THE ELECTRICIAN:

A WEEKLY JOURNAL OF

THEORETICAL AND APPLIED ELECTRICITY AND CHEMICAL PHYSICS.

VOLUME XIII.

FROM MAY 17 TO NOVEMBER 8, 1884.

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at "THE ELECTRICIAN" Offices, 1, Salisbury-court, Fleet-street, E.C.

1884.

Digitized by Google

INDEX TO VOL. XIII.

A

Accident at Health Exhibition, 480, 494, 502.
Africa, West, A Cable to, 542, 554.
American Science Association, The, 495.
Ammen, Admiral D., Sounding Apparatus, 457.
Anderson, Sir J., Cables in War Time, 540.
Arago Disc Dynamo, 351.
Artificial Lighting, by R. E. Crompton, 210.
Ayrton and Perry, Professors, New Form of Spring for Meters, 85, 109.

B

B.T.K. System at Colchester, 117, 137, 474.
Bandsept, A., Tubular Carbons, 61.
Barker, E. R., Galvanometer and Battery Test, 247.
Bartholomew's Hospital, Electrical Department, 261.
Batteries, Primary :—
  Crova and Garbe's Standard Cell, 296.
  for Electric Lighting, by I. Probert, 161, 183.
  Lalande and Chaperon's 90.
  Seat of E.M.F. in, by Dr. Lodge, 497.
Batteries, Secondary :—
  Discharge of, by Professor Frankland, 471.
  Electrolysis of Sulphuric Acid in, 234.
  Swan and Brush Patents, 95.
  Their Use in Telegraphy, by W. H. Preece, 498.
  Working Tramcars in Brussels, 94.
  See also CORRESPONDENCE and NOTES.
Battery and Galvanometer Test, 247.
Beetz, W. H., Electrometric Measurements, 394.
Belgium, Long Distance Telephoning in, 560.
Bell, Jenkin's Alarm, for Greenhouses, 203.
Berlin, Cost of Electric Lighting in, 479.
Bidwell, S., Physical Properties of Metals, 35.
Bismuth, Variations in Physical Properties of, 479.
Blakesley, T. H., Currents and Conductors, 106.
Blyth, Professor J., Solenoid Galvanometer, 432.
Body, The, and Currents, 108.
Books, Notices of (*see* REVIEWS).
Boston or Bernstein Lamp, 59.
Bottomley, J. T., Daniell's Cell, 574.
Bottomley, J. T., Loss of Heat by Radiation, 441.
Bottomley, J. T., Permanent Temperature of Conductors, 538, 559.
Boys, C. V., Magneto-Electric Induction, 225, 462.
Brackett's Energy Meter, 80.
Bramwell, Sir F., Address to Section G, British Association, 421.
Breguet's Theory of Dynamos, 280.
Bridge for Measuring Small Resistances, by E. C. Rimington, 89.
Bristol Corporation *v.* United Telephone Company, 192.
British Association Meeting at Montreal :—
  Admiral Ammen on Sounding Apparatus, 457.
  J. T. Bottomley on Loss of Heat by Radiation, 441.
  Sir F. Bramwell's Address to Section G, 421.
  Captain Cardew on a New Voltmeter, 431.
  Professor Frankland on the Discharge of Accumulators, 471.
  Leading Article on, 392.
  Dr. O. J. Lodge on Dust, 459.
  Dr. O. J. Lodge on the Seat of E.M.F. in the Voltaic Cell, 497.
British Association Meeting at Montreal :—
  W. H. Preece on the Watt and Horse-Power, 473.
  W. H. Preece on Secondary Batteries for Telegraphy, 498.
  President's Address, 373.
  Report of Committee on Screw Gauge, 417.
  Sir H. Roscoe's Address to Section B, 400.
  Summary of Proceedings, 470.
  Sir W. Thomson's Address to Section A, 397.
  Sir W. Thomson on a Gyrostatic Compass, 492.
Brush Dynamo, The, 304.
Brush and Swan Accumulator Patents, 95.
Brussels, Electric Lighting of the Grand Place, 396.
Brussels, Tramcars Worked by Accumulators in, 94.
Bucharest, Electricity in, 577.
Bürgin Dynamo, The, 305.

C

Cable Maintenance, One Phase of (Leading Article), 534.
Cable Stories, Old, by F. C. Webb, 55, 203, 272, 365, 415, 436, 510.
Cable Testing, by H. C. Mance, 21.
Cable to West Africa, 542, 554.
Cables, Submarine, Protection of, 10, 36.
Cables in War Time, by Sir J. Anderson, 540.
Cambrian Railways and Postmaster General, 330.
Carbon, Electro-deposition of, by Dr. Gore, 340.
Carbons, Tubular, by A. Bandsept, 61.
Cardew, Captain, New Voltmeter, 431.
Carus-Wilson's Electric Governor, 226.
Cary's Telephone Signal, 512.
Cauderay's Electric Meter, 439.
Chandler, Professor, Electricity and Magnetism, 18.
Chemical Corrosion and Voltaic Current, by Dr. G. Gore, 30.
Chlorate of Silver, Electrolysis of, by Dr. Gore, 341.
City and Guilds Institute, The :—
  Examination Papers, 160, 182.
  Leading Article on, 204.
  Programme of Central Institution, 414, 419.
  Technical College at Finsbury, 181.
Clock Setting Mechanism, Kettell's, 453.
Coast Defence, Williams's System of, 518.
Colchester, B.T.K. System at, 117, 137, 474.

COMPANIES' MEETINGS, REPORTS, &c. :—
  Anglo-American Brush, 288.
  Anglo-American Telegraph, 287, 308.
  Brazilian Submarine Telegraph, 544, 580.
  Consolidated Telephone, 70, 285.
  Cuba Submarine Telegraph, 287, 312, 330.
  Direct Spanish Telegraph, 444, 483.
  Direct United States Cable, 236, 283.
  Eastbourne Electric Light, 311.
  Eastern Telegraph, 215, 236.
  Eastern Extension Telegraph, 504, 522.
  Faure Accumulator, 144, 216.
  Globe Telegraph, 264, 284.
  Great Western Electric Light, 484, 503.
  India Rubber, 263.
  Lancashire and Cheshire Telephone Exchange, 332.
  Lancashire Maxim-Weston Electric, 46.
COMPANIES' MEETINGS (*continued*):
  London Platino-Brazilian Telegraph, 43.
  Maxim-Weston Electric, 45.
  National Telephone, 312, 331.
  Pilsen Joel Electric Light, 379.
  River Plate Telephone, 72, 355.
  Submarine Cables Trust, 24.
  Submarine Telegraph, 287, 310.
  Telegraph Construction, 263.
  Telephone Company of Ireland, 524, 544.
  United Telephone, 239.
  West Coast of America Telegraph, 236, 262.
  West India and Panama Telegraph, 44, 524, 543.
  West Middlesex Electric Light, 264.

Compass, Gyrostatic Model of, by Sir W. Thomson, 492.
Condenser, Measuring the Capacity of, 297.
Conductors and Currents, by T. H. Blakesley, 106.
Conductors, Economical, by W. L. Hooper, 274.
Conductors and Heating, by Professor G. Forbes, 16, 39, 63, 82.
Conductors, Permanent Temperature of, by J. T. Bottomley, 538, 559.
Congress, Electrical at Philadelphia :—
  Report of Discussions, &c., 454, 459, 477.
  Professor FitzGerald on the Theory of the Dynamo, 558.
  Professor Rowland's Address as President, 481, 500.
  Professor Rowland on the Theory of the Dynamo, 516, 635.
Copper-Oxide Battery, Lalande and Chaperon's, 90.
Cores, Induction in, by O. Heaviside, 54, 103, 133, 199, 333, 362, 386, 430.

CORRESPONDENCE TO "THE ELECTRICIAN :"—
  Accident at Health Exhibition, 493.
  Accumulators (*see* BATTERIES, Secondary).
  Allbright, J. F., Electric Lighting for Lighthouses, 320.
  Allbright, J. F., Lamps with Dynamos and Batteries, 254.
  Aldred, W., What is Electricity ? 393.
  Avertisseur Electro-Automatique, 436.
  Ball's Unipolar Dynamo, 515.
  Bain, Alexander, 179.
  Banks, W., Electric Launch Trial, 456.
  Batteries, Primary :—
    FitzGerald's Method of Measuring Internal Resistance, 393.
    For House Lighting, 205, 254, 277.
  Batteries, Secondary :—
    F. S. V. at Bristol, 58.
    Gadot's Improvements in F.S.V., 320.
    Zinc-Lead, 37.
  Blakesley, T. H., Electro-Dynamics, 277.
  Braithwaite, J. B., Accumulators, 58.
  Bright, Sir C. T., Siemens' Electro Dynamometer, 345.
  Capito, C., Electric Launch, 435.
  Central Station Lighting, 58.
  City and Guilds Telegraphy Examination, 346.
  Condenser, Capacity of, 345.
  Consolidated Telephone Company's Meeting, 320.
  Conversazione at King's College, The Lighting at, 254.
  Crompton, R. E., Cost of Electric Lighting, 154.
  Cruto Lamp, 127.
  Current Carrying Capacity of Wires, 178, 206, 345.

Digitized by Google

CORRESPONDENCE (*continued*):
Current, Passage of, through a Conductor, 394.
Currents, Accidents from, 109.
Davey, Edward, 533.
Davey, St. G. W., The Roussy Moderator, 555.
Deane, H. P., Inventions Exhibition, 475.
Dundee Telephone Company, 475, 493, 533.
Dunston, R. E., The Roussy Moderator, 555.
Dynamometers, 229.
Dynamos:—
Ball's Unipolar, 515.
v. Batteries, 205, 254, 277.
Calculating the Relation of Resistances, 253.
Compound, 455.
Dimensions of, 475.
Formulæ, &c., Wanted, 299.

THE ELECTRICIAN:

A WEEKLY JOURNAL OF

THEORETICAL AND APPLIED ELECTRICITY AND CHEMICAL PHYSICS.

No. 1.—Vol. XIII. SATURDAY, MAY 17, 1884. Price 4d.

NOTES.

The West Indies.—Telegraphic communication between Key West and Havana is interrupted.

Telegrams for the West Indies.—Telegraphic communication between Key West and Havana is interrupted.

Central News v. Eastern Telegraph and Others.—The further hearing of this case will be taken next Saturday.

Brazilian Submarine Telegraph Company.—The traffic receipts of this company for the week ended 2nd instant amounted to £3,797.

Brussels.—It is proposed to hold an international exhibition in 1887. Electricity is expected to hold an important place in this exhibition.

Telpherage.—Professor Fleeming Jenkin's paper on this subject was read on Wednesday at the Society of Arts. The paper will be given in our next issue.

A New Atlantic Cable.—A Reuter's telegram from Halifax states that the "Faraday" had successfully laid the shore end of the new Atlantic cable on Friday last week.

Lundy Island.—Telegraphic communication has been extended from the Postal Telegraphic Office at Hartland to a new signal station established by Lloyds on Lundy Island.

Egypt.—Telegraphic communication between Korosko and Abou Hamed was destroyed on Monday last. Debbeh is now the last station to which telegraphic communication extends.

Personal.—We understand that Mr. F. C. Phillips has left the Hammond Company as their managing electrician, and intends practising as an electrical and consulting engineer.

Society of Telegraph Engineers.—At the next meeting of the Society of Telegraph Engineers and Electricians, May 22, Mr. Preece is going to give a paper on the results of the three electrical congresses of Paris.

Philadelphia.—It is reported that all the available space in the Philadelphia Electrical Exhibition building has been applied for, and that the question of building one or more annexes is now under consideration.

Western and Brazilian Telegraph Company.—The traffic receipts for this company for the week ended 9th inst. were £2,916, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

Direct Spanish Cable.—The duplicate cable of this company between Kennack Cove, Cornwall, and Bilbao, Spain, has been successfully laid, and is in perfect working order. The cable was manufactured and laid by the Telegraph Construction and Maintenance Company.

Telephones in Russian Fortresses.—The St. Petersburg *Novoe Vremya* of 10th instant states that the War Department has successfully completed an experiment with telephones at the Sweaborg forts, and proposes the adoption of this means of communication in fortresses generally.

Great Northern Telegraph Company.—This company's bankers, Messrs. C. J. Hambro and Son, No. 70, Old Broad-street, E.C., are now prepared to issue new share certificates, with fresh coupon sheets, in exchange for the old certificates, which are to be given up with the talon attached.

Personal.—His Majesty King George of the Hellenes has been graciously pleased to confer upon Baron John de Normann, Superintendent of the Mediterranean Extension Telegraph Company at Corfu for the last 20 years, the Gold Cross of Knighthood of the Most Noble Order of the Saviour, as a mark of his sovereign approval.

Lundy Island.—Telegraphic communication has been extended from the Postal Telegraph Office at Hartland to a new signal station established by Lloyd's on Lundy Island. The fee charged by Lloyd's for signalling telegrams to and from passing vessels, or for reporting vessels, is 3s. 6d. if the message or report does not exceed twenty words, additional words being charged for at the rate of 6d. for five words or fraction of five words.

Ransomes, Sims, and Jefferies.—This old and well-known firm has on account of the continuous extension of business, and the desirability of fixing the capital employed in it, been converted into a private limited company, constituted under the Companies Acts, 1862 to 1883, and has been registered, and will be henceforward carried on under the name of Ransomes, Sims, and Jefferies (Limited). The new company has acquired all the assets, and will discharge all the liabilities of the partnership. The management of the business of the company will be continued by the partners of the late firm.

Reported Massacre of Berber Telegraphists.—The Cairo correspondent of the *Daily News* stated on Tuesday last that the sub-inspector of the telegraph had escaped from Berber to Korosko, but his colleagues remained at Berber waiting for camels, and owing to the absence of telegraphic communication they received no instructions, were captured, and, it is said, massacred, while endeavouring to reach Abou Hamed, by the rebels, by order of the Emirs of the Mahdi.

The Post Office and the Telephone Companies.—In reply to Mr. Sexton, Mr. Fawcett stated in the House of

Digitized by Google

Commons last week that no royalty had ever been demanded from the telephone companies for payments made to them for advertisements in their own catalogues. There was a royalty demanded for a certain payment of one guinea made by some subscribers in addition to their ordinary rent, but the nature of this payment being explained the demand was at once withdrawn.

FIELD TELEGRAPHING.—Under instructions from army headquarters a committee has been ordered to assemble at Alder shot and report on the value of the various methods of effecting telegraphic communication between outposts and the main body in the field. The committee is constituted as follows:—President: Major-General Lyons, C.B. Members: Lieut.-Colonel Hale (1st Battalion Scottish Rifles), Lieut.-Colonel Hanning Lee (2nd Dragoon Guards), and Lieut.-Colonel Hamilton, R.E.

EARTH CURRENTS.—We have received from M. E. Blavier a pamphlet containing the results of his investigations upon earth currents. This work is entitled "Etude des Courants Telluriques," par E. E. Blavier, Inspecteur-Général au Ministère des Postes et Télégraphes, Directeur de l'Ecole Supérieure de Télégraphie, nd is published par ordre de M. le Ministre des Postes et des Télégraphes. The work contains a beautiful series of illustrations of curves obtained during the investigations.

TELEPHONY IN THE NORTH.—Telephonic communication is now established between Sunderland, South Shields, and Newcastle, under the auspices of the Northern District Telephone Company, who have arranged with the Postmaster-General for a trunk line. The yearly subscription for the use of the trunk wire between Sunderland and Newcastle by exchange subscribers is £6 10s.; and for that between Sunderland and South Shields £6. The annual charge for the use of the trunk wire from Newcastle to North Shields is £6.

ELECTRIC LIGHTING AT NOTTINGHAM.—The ground-floor room of the Central Free Library has now been lighted by 72 20-candle Swan lamps, the current being supplied from a Ferranti machine driven by the engine belonging to the Technical Schools. The lights are perfectly steady, and during one evening, though the library was crowded, the temperature rose only 2° F. The lamps are 41-volt lamps arranged three in series, the E.M.F. at the ends of the cables being 123 volts. The whole of the installation has been carried out by the staff of the physical department of the college.

THE GIRALDA AT SEVILLE.—A letter from Seville, says *The Times*, reports that a terrible thunderstorm, which occurred on the 25th of April, did serious mischief to the Cathedral and its famous campanile, known as "the Giralda." Great injury has been done to the picture, of considerable artistic value, over the southern entrance of the cathedral, the so-called "Puerta de los Palos," representing St. Sebastian before the Emperor Diocletian. It is reported that as soon as Queen Isabella heard of the accident she telegraphed that she would defray the expenses of erecting conductors out of her private purse.

THUNDERSTORM.—About half-past four o'clock on Monday afternoon a storm, accompanied by loud and prolonged peals of thunder and vivid flashes of lightning, passed over London, doing considerable damage to property in the West. No. 141, Westbourne-terrace, Paddington, a large dwelling-house at the corner of Westbourne-terrace and Bishop's-road, was struck by lightning, causing a chimney, ten feet high by eight feet wide, to fall with a loud crash into the footpath beneath, but fortunately not injuring anybody. The roof of 28, Bishop's-road also was destroyed, but the only person on the premises was the caretaker, who was not injured. The goods in the house were severely damaged by the falling *débris*.

NEW BOOKS.—The long-promised work of Mr. J. E. H. Gordon on electric lighting has been issued. It is published by Messrs. Sampson Low and Co., the exact title being "A Practical Treatise on Electric Lighting." It is well illustrated and carefully printed, as might, indeed, be expected of any book issued by this firm. Our notice of the text must be left to another date, except, perhaps, to say that in many respects it inaugurates a new departure. The electrical principles upon which this particular application of electricity is founded are first discussed. Then we come to chapters on incandescent lamps, on arc lamps, on dynamos, on storage, photometry, meters, and so on, concluding with a series of useful tables.

SECONDARY BATTERIES.—*L'Electricien* contains an article by M. Emile Reynier on a zinc accumulator which appears to be a secondary battery, with an anode (in charging) of lead and a cathode of zinc. The ratio of stored energy to weight in the case of several batteries, inclusive of the above, is given by the author as follows:—

	Kilogrammètres.
1 kilogram of the Planté accumulator, small size, "formed" by the inventor, stores	1,500
1 kilogram of the Faure accumulator, old form, weighing 8 kilograms, stores...............	3,000
1 kilogram of the Faure accumulator, more recent form, weighing 30 kilograms stores	4,400
1 kilogram of the present zinc accumulator of the form, weighing 17 kilograms stores...............	7,600

We are not, however, informed how the zinc, when once dissolved, can be reduced by the charging current without a ruinous waste of energy expended in the evolution of hydrogen gas.

COST OF THE ELECTRIC LIGHT IN NEW YORK.—"The following contracts for electric lighting," says the American *Electrical Review* of May 3, "in this city were awarded on the 17th inst for ensuing year:—The United States Electric Illuminating Company was awarded a contract at seventy cents per night for each lamp for lighting Battery Park, City Hall Park, Washington-square, Tompkin-square; Broadway, from Battery-place to Twelfth-street; Fifth-avenue, from Washington-square to Thirteenth-square; Bleecker-street, from Broadway to Eighth-avenue; South-street, from Whitehall to Grand; Eighth-avenue, from Bleecker to Fourteenth-street; Gansevoort Market-square; East Broadway, from Chatham-square to Grand-street; and West-street, from Battery-place to West Eleventh-street. The Brush Electric Light Company was given the contract at the above-named price for electric lights in the following territory: Fourteenth, Twenty-third and Forty-second-streets, from the East River to the Hudson; Fifty-third-street, from Third to Ninth-avenue; Seventh-avenue, from Fourteenth to Fifty-ninth-street; Broadway and Fifth-avenue, from Fourteenth to Fifty-ninth-street; Fourth-avenue, from Eighteenth to Forty-second-street, and Union and Madison-squares.

ELECTRICITY AND RAILWAYS.—In the current number of the *Railway Engineer* the question of the application of electricity to railway purposes is commenced, and it seems that electricity is to play a prominent part in the railway work of the future, for the writer says, "Through all this cloud of doubt and beyond all these obstacles we plainly see in elec-

Digitized by Google

tricity the vital principle of railway work in the future. Not only large stations will be lighted, but all signal lamps, signal boxes, and small stations throughout the line. The head and tail lights of trains, and all the carriages will be illuminated with the cool, soft, pure, beautiful light; the sickly glare and horrible odour of bad gas and rank oil will be barbarisms of the past; from end to end of every train perfectly easy and reliable communication between guard, passengers, and driver will be maintained by the electric current; electricity will apply the brakes; the driver and guard will at all times know the exact state of the line a thousand yards in front or rear; the power will be converted into heat for the purpose of warming the carriages; and just as the world will be growing alarmed at the approaching exhaustion of our coal beds, electricity, conveying mechanical work from the tidal waves, will take the place of our grand old locomotive, and draw the heaviest trains at a higher speed and under conditions of greater safety than the fastest and best equipped express of to-day."

Press Messages on Military Lines.—It is somewhat strange that the statements in a letter from "Cush" to the *Daily News* are published in face of Colonel Webber's evidence at the trial. "Cush" writes:—"The Lord Chief Justice said or implied that press messages were sent over that wire free of charge, and if they, the military, obliged the press in that way they had a right to see what was received. On the contrary, however, a through charge of 2s. 6d. per word was made by the military from Kassassin to England, at which rate I sent several messages myself. The rates, I think I am right in saying, were:—Alexandria to London 1s. 7d. per word, Alexandria to Ismailia 6d. per word, and Ismailia to Kassassin 5d. per word. So, after all, the military were not quite so obliging as they appeared to be, as they only charged 8s. 4d. for 20 words 20 miles, which in England would be sent for 1s. Considering this charge, surely Sir Charles Wilson had no right to read, or, if he had to read, surely not to divulge the Burleigh message. By making this known I think it will do something towards helping the Central News to win the point of law now under consideration, and thus have a verdict in their favour, which they so justly deserve." The only statement here to be considered is that about the charge from "Kassassin to Ismailia," or rather we should say want of statement, for there is not one word of proof that a charge was made on the military line. All other lines except this were lines erected, we should imagine, as ordinary business lines, and belonged either to the Egyptian Government or to the Eastern Telegraph Company, over which of course a charge was made. At Ismailia at the Egyptian office charges would naturally be made. At Kassassin Col. Webber said nothing was paid, and this more than once.

Brush Electric Light and Power Company of Scotland.—This company, acting under their directors' advice, and with unanimous consent of shareholders, went into voluntary liquidation on October 16th, 1883. Their share capital consisted of 22,000 shares of £5 each, with £2 10s. paid, and 8,000 shares of £5 each fully paid, their cash in hand being about £30,000, as against sundry liabilities. Three of the directors were appointed liquidators. Many intricate questions arose, for it seems by law that in a liquidation where two classes of shares exist, as above indicated, the fully paid shareholders can insist that the liquidator shall first call up the balance remaining upon the partially paid shares, so as to put all on the same level, and then divide equally. This of course would have acted disastrously upon the 22,000 shareholders, and a splendid opening for the lawyers seemed imminent. By tact, management, and mutual forbearance on each side the liquidators succeeded in settling all disputes, in keeping the company out of court, and reducing its law expenses incident to the liquidation to a sum under £200, and this with many threatening actions where contracts had to be compromised, and sales of going installations effected where under contract for years. The negotiations for a surrender of the license to the Anglo-American Brush Corporation was effected (without legal expenditure) by the liquidators themselves, and thirty-eight days from the passing of the resolution to wind up a dividend of 10s. and 20s. per share was returned, followed at an interval of two months by a further 5s. 10d. and 11s. 8d. per share, and within seven months the shareholders were called to the final meeting when the full accounts were placed before them, the fourth and last dividend making nearly 20s. per £2 10s. share agreed, and the company dissolved.

Central News v. Eastern Telegraph Company.—With reference to this case Mr. J. F. Andrews, editor of the Exchange Telegraph Company, writes to the *Daily News*:—"I have today read your comments upon the trial which terminated on Wednesday, and to which the Exchange Telegraph Company was a party. In the course of them you remark, 'Now the Exchange Telegraph Company, of which Sir James Anderson was the chairman, had no correspondent in Egypt.' A similar statement was made by the counsel for the plaintiffs, but the evidence not only of the defendants' witnesses, but that of the plaintiffs, showed that this company was represented by Mr. Tait, who followed the army under Sir Garnet Wolseley, and was sent out from London for that purpose, and by Mr. Atkins at Alexandria. Our payments to the Eastern Telegraph Company are ample proof of the activity of our representatives during the whole time of the Egyptian crisis in 1882. During that period our telegrams were appearing daily in the newspapers; if, therefore, such a statement, made by an independent and impartial journal, were allowed to pass uncontradicted, the inference that might be drawn would probably be more prejudicial to the interests of this company than any charges emanating from a rival agency. On the day of the battle of Tel-el-Kebir Mr. Tait was at Ismailia, and his telegram was produced in court as a commentary upon the charge against the Eastern Telegraph Company of 'expediting Diocles.' The telegram to Diocles left the Egyptian Telegraph office 38 minutes after the Burleigh telegram, but was not delivered in London until five or six hours after it. I am not giving you my own knowledge, but facts proved by witnesses in court. As your misapprehension of them has been stated in your columns, I hope your pages will be open to a correction."

Property in Cablegrams.—In the House of Commons, on Tuesday last, Mr. T. P. O'Connor (for Mr. Labouchere) asked the Postmaster-General whether it was his intention to take any action with a view to make the milking of cablegrams to this country by the officials of cable companies illegal; and to ensure, so far as is possible, the secrecy of all cablegrams sent to and from this country over land lines belonging to the Post Office.—Mr. Fawcett replied: Although the public is sufficiently protected by the existing law against messages passing over wires belonging to the Post Office being divulged, I fully admit the importance of, if possible, providing similar protection to foreign telegrams passing over the wires worked by private companies. The question is not free from difficulty, but I should be very glad to consider whether a clause could not be framed to be inserted in the Post Office Protection Bill to meet such a case as that referred to by my hon. friend. It has been intimated by some of the most important cable companies that they would be glad to see such a clause passed by the House. The Post Office Protection Bill, which now stands

Digitized by Google

for second reading, is at the present time blocked, and this being the case, I am prevented until a second reading is obtained from putting on the paper any new clause that it may be intended to move in committee to carry out the object desired.—Mr. T. P. O'Connor asked whether the Postmaster-General would have any objection to consider the advisability of introducing into the proposed clause a provision which should ensure that no precedence should be given to the cablegrams of directors of cable companies.—Mr. Fawcett: If I can only get the second reading of this Bill, which is a purely administrative Bill, passed I shall put at once on the paper the form of clause, and shall then be glad to receive any suggestion.

Influence of Stress on the Electrical Resistance of Iron and Steel Wires.—In the *Proceedings* of the Manchester Philosophical Society, Mr. W. H. Johnson, B.Sc., describes some experiments made by him as follows:—A piece of piano steel wire, about 0·040 inch diameter, was found to have a resistance of 0·418 ohm. A heavy longitudinal stress causing a temporary elongation of 3 per cent., but not sufficient to produce any permanent strain, was applied, and the resistance observed was 0·422 ohm, the temperature in both cases being the same. If the resistance per meter gramme of the wire had been unaltered by the *stress*, the observed resistance of the wire under stress should have been 0·443 ohm, or some 5 per cent. more than that observed. The resistance of hardened and tempered steel wire thus appears to *decrease* 5 per cent. under stress. Experiments were next made on hard iron wire, about the same diameter as above, 1·774 metre long and 0·2274 ohm resistance. Under longitudinal stress, causing a temporary elongation of 0·33 per cent., the resistance was found to be 0·232 ohm. Now, if the wire had been unaltered in resistance by stress, the observed resistance should have been 0·229 ohm. Thus it appears that the resistance of hard or unannealed iron wire, unlike piano steel, is *increased* by stress some 1½ per cent. The figures denoting the percentage of change of resistance caused by stress are of course only approximate, but serve well to denote the direction of the change. In both sets of experiments the iron and steel wires returned to their original resistance when the stress was removed. The stress applied to the steel wire was many times that applied to the iron wire, so it is just possible that the steel wire under a small stress would have behaved like the iron wire and increased in resistance. The stress applied to both iron and steel wires was the highest they would bear without permanent change of length.

Electric Light at the Health Exhibition.—On the evening of the opening day of this exhibition a portion of the electric lighting was in service, enough to show the visitors some of the most attractive exhibits. The Hammond Company had the whole length of the western corridor lighted with bright arc lights, and also illuminated the west quadrant in like manner, causing crowds to congregate and criticise the long series of historical costumes which this indication already makes certain will be one of the most popular attractions. The entrance vestibule and the dining rooms were beautifully lighted by incandescents by the Edison-Swan United Company, and the great south gallery by Siemens with a thousand Swan incandescents as before. The former fish market, now a dining room on the Duval system, with its number of maid servants in blue serge dresses and white aprons, was lighted by many arc lights, and presented a very cool and pleasant appearance. The Central Gallery, formerly the Newfoundland Court, was again lighted by the Jablochkoff Company, the lights having a far better aspect than formerly, being now shaded by the Trotter prismatic lamp-glasses. The gardens were exceedingly beautiful with the soft light of the moon and the glitter of hundreds of Venetian lamps and Chinese lanterns, which are distributed and displayed by Mr. Pain with more even than his usual tact and talent. The windows of the corridors are arched externally with little yellow lights which form jewel-like settings to the bluish glare seen through the windows from the electric arcs within. The reflection of the various coloured tiny Vauxhall lamps in the water pools and basins, the wreaths of similar coloured lights around the pedestal of the Albert Statue, and the occasional gleams of the strong electric lights between the trees contrasting with their deep shadows combined to render the scene most charming. Two military bands added excellent music to the other outdoor attractions. This lighting and music will be continued every night. The number of visitors on the opening day exceeded 14,000.

He Forgot to Put in the Wires.—One or two good stories come from Washington anent the laying of underground cables there:—The Bankers' and Merchants' Telegraph Company in this city are putting their wires under ground. The other day they made a discovery that was amusing to others, but not to the man having in charge the underground work. He had completed the work for four squares when a thought struck him. He was very sorry that he had not been struck by it before. He had made the underground receptacle for the wires and covered it over according to the most approved methods, but he had neglected to put in the wires or anything by which they could be pulled through. He tried air pressure and everything he could devise to force a wire through the underground trough. But nothing availed. The whole thing had to be taken up and the work done over again. Mr. Morrill Marean, manager of the Washington office of the Western Union Company, told a *Critic* man about this. He continued.—"It reminds me of the time they had in London in 1857 or '58. The telegraph wires in that city have always, for the greater part, been under ground. The main wires are laid through the big tunnels, which accommodate also the gas and sewer pipes. These tunnels are big enough for a man to walk through easily. Of course there is no trouble about inspecting the wires or repairing or replacing them whenever it becomes necessary. But the pipes containing the lateral wires, running off for two or three miles from the main line, are small ones. At the time of which I speak one of these lateral wires was hauled out to be repaired. The men doing this work failed to attach to it a leading line, by which the wire could be drawn through again. The means employed to correct the error were very unique. A large rat, with a fine steel wire, was put in the pipe. Behind there was thrust a ferret. The rat ran from the ferret a short distance and stopped. It was feared that he would show fight and be killed. But he started on again. He ran through the whole length of the pipe, and brought out the wire in good style, though closely pushed by the ferret."—*The Operator*.

Professor Huxley on Science Teaching.—Professor Huxley was examined on Tuesday before the Select Committee of the House of Commons on the Education, Science, and Art Departments. He stated that in his opinion greater attention should be paid in our public schools to physical science. The Endowed Schools Commission was appointed to a great extent on account of the general state of apathy which existed in connection with the endowed schools.—Sir John Lubbock: Has it not been one of the schemes to secure that greater attention should be given to modern languages and physical science?—Yes, there is a distinct provision that a certain proportion

Digitized by Google

of marks should be given to science and modern languages. The system, however, is not well carried out in the public schools. Not more than two hours a week are given to science. There is no doubt that the Oxford and Cambridge School Examination Board Regulations tend to handicap science extremely; but while that is the case I should be sorry to be supposed to blame the examiners, because I do not see how they can adopt a different course to that which they at present take. They found their examinations on what is taught in the schools, and the schools found their instruction on the requirements of the examiners. No doubt if the examining boards gave a greater value to science it would act as an inducement to the educational bodies to improve their system. I have not the slightest desire to interfere with the study of the classics, but I look upon the present system as wrong from top to bottom. The subjects on which most stress is laid are really luxuries, while those which are regarded as luxuries are really the most essential. For instance, it is a common thing for a young man in this country to be familiar with the classics, and to be totally unfamiliar with English literature, never having made it a study. That strikes me as a deadly harm to literature. I do not object to it as a man of science, but I object to it from my admiration for literature. In the same way as to history: it is possible for a young man to obtain the highest honours at our Universities without having any idea at all of the historical growth of his own country and the particular institutions under which he lives. In this matter science is no worse off than a great many other things. The present system of education in the country shuts out young men from many employments for which they should be eligible, and tends to the employment of foreigners.—The Chancellor of the Exchequer: You, having laid down a principle, would like to see it carried out, and would trust for its fulfilment to public opinion?—Professor Huxley: Yes; but I would give public opinion a lever through the State.—But you would really trust to immediate public opinion rather than to any active intervention on the part of a department?—No; I think an influential Minister, with a seat in the Cabinet, might do a great deal. It would be his business to judge in what direction the educational system was tending, and to enforce on the educational bodies a modification of their system in the desired direction. I would give the Minister power to insist upon more time being given to science and modern language.

Lightning and Collieries.—At the last ordinary monthly meeting of the Manchester Geological Society, Mr. John Knowles, M. Inst. C.E., read a paper describing the descent of an electric current into the New Rivin Pit, belonging to Messrs. Andrew Knowles and Sons. During a thunderstorm which took place on the 21st February a shock was felt in the workings at the New Rivin Pit, near Bolton. The colliery was about three miles from Bolton, the upcast pit being about 30 yards from the road and the downcast 50 yards. The upcast pit was 9ft. in diameter inside the brickwork, which rose as a chimney about 24ft. above the ground. In this pit there was no winding, but there was one pulley 5ft. in diameter, which stood without rope, to be used with a portable capstan engine in case of emergency. There were also two folding iron doors, which took up a space in the chimney 8ft. high by 5ft. wide. The pit was 97 yards deep. The downcast pit was also 9ft. in diameter and 97 yards deep, with a sump of 14 yards further. In the pit were four iron wire guides, 1¼in. in diameter, and two iron wire ropes between the cages; the former went into the water at the sump, and the latter terminated just below the landing plates. There were also a bell wire of galvanised iron and 3in. steam pipes mostly uncovered. The two cages were of iron, a steel rope being used for one cage and an iron rope for the other. This pit was surrounded with the ordinary cast plates and rails, but there was not any connection with the chimney of the upcast shaft. There were the usual buildings about the pits; also a chimney 6ft. square and 20 yards high, but no lightning conductor on it. At the bottom of the downcast pit there were the usual plates and rails, with the steam pipes extending to two engines on the east side and one on the west. Those going eastward were laid up a brow, with a gradient of one in three, to the Lower Three Yards mine, and then a short distance on a level to the first engine, which wound up the downbrow in this mine. At this point there was a rise tunnel to the Lower Yard mine, worked as a self-acting incline. The steam pipes were carried to the top of this tunnel, and then on a short level to the engine at the top of a downbrow in the Yard coal, where a wire rope was used to wind the coal to that point. There was also a wire rope used in that brow to work a small pump, which forced water to the top of the incline, whence it ran to the pit. On the west side the steam pipes were laid on a level in the Lower Yard mine to a small engine, which wound coal up a dip tunnel from the Lower Three Yards mine. This engine had a 6in. cylinder, with 10in. stroke, the dip tunnel being 48 yards long, with a gradient of 1 in 5. The electric current appeared to have struck the chimney at the top of the upcast pit about 2:30 p.m. on the day named. It displaced a large quantity of brickwork, and then came down outside the chimney, striking the ground close to it and making a large hole. It then went along the ground to the cast plates at the top of the downcast pit, and it was presumed went down the steam pipes and so into the workings—on the east side going through the Yard downbrow engine, and along the rope to the waggons, and on the west side passing along the pipes to the engine, where the manager was standing. The strength of the current must have been very great as experienced by a waggoner seated four or five yards from the bottom of the downcast, as he stated that he saw a brilliant flash, and heard a great noise, which sounded as if in the pit. He had the heel of his clog on one of the plates at the time, and felt a tingling sensation in his leg, which lasted a day or two, and the sole of his clog was burnt, as if hot iron had been drawn over it. Other men in the pit also experienced a sensation which they described as resembling the shock received at an electrifying machine. The manager, who was on the west side in the Lower Yard mine, at a small engine 300 yards from the pit, had his hand on the steam handle and felt a shock which numbed him for a few seconds, so that he could not see or move, and was afterwards so completely prostrated by the effects of the shock that he was confined at home to bed for six days. From the statements made by the men it would appear that there must have been a very strong current of electricity passing down the ironwork of the pit, and it was fortunate that much of it was distributed before it reached the workmen in contact with any metal. The manager being the nearest in direct contact seemed to have suffered the most, as the waggoner was only connected with the plates by a wooden clog, and others at the bottom of the Lower Yard coal incline only received a shock after it had passed many means of distribution. Two other cases of a similar kind had occurred, one at the Tanfield Moor Colliery on the 12th July, 1880, on which a paper was read before the members of the North of England Institute of Mining and Mechanical Engineers, and the other at West Thornley Colliery, on the 11th December, 1883, with regard to which a paper was also read before the same society.

ELECTRO-CHEMISTRY.—Inorganic.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 605, VOL. XII.)

Separation of Thallium.—Tl. Electro-chemical equivalent = 204. A monad cation. Zinc coats itself with metal in solutions of salts of thallium, but tin usually does not. According to Lamy, zinc precipitates the metal from the solutions of the nitrate and sulphate in the form of brilliant crystalline laminæ. I found that crystals of silicon had no reducing effect on a solution of fluoride of thallium containing free hydrofluoric acid. According to A. Cossa, aluminium deposits by simple immersion, metallic thallium from a solution of thallium chloride at 90° C. (Watts's "Dictionary of Chemistry," Vol. VII., p. 54).

Solutions of the salts of this metal are easily decomposed by a feeble current, and the metal deposited in beautiful crystalline plates upon the cathode. I electrolysed an aqueous solution of the fluoride by a current from a single Smee's element, a thallium anode and a platinum cathode. It conducted freely, and quickly gave a metallic deposit, in long feathery crystals, like those of electro-deposited tin, but of a less white colour.

According to L. Schicht, acidulated solutions of nitrate and sulphate of thallium were not precipitated by a separate current. From ammoniacal solutions thallium was deposited upon the cathode together with much gas; whilst at the anode there appeared blackish brown thallium oxide, much resembling peroxide of lead. The current was from four Meidinger-Pincus elements, and yielded the metal in a spongy state and of a dark colour; but by using only two or three cells, fine permanently adhesive metal was obtained. From neutral solutions the metal is imperfectly precipitated on account of the acid which is liberated, but in alkaline ones the metal is bright and solid, and the deposition is complete. The deposit redissolves readily in sulphuric acid. (*Chem. News*, Vol. XLI., p. 280; also Vol. XLVII., p. 209.)

Electrolysis of Sulphate of Thallium.—TL_2SO_4. Molecular weight = 504. Aluminium immersed in a slightly acid solution of thallium sulphate, becomes coated in ten days with regular octohedra of thallium alum (Watts's "Dictionary of Chemistry," Vol. VII., p. 54). A solution of sulphate of thallium, acidulated with sulphuric acid, deposits its metal upon zinc by simple immersion (*Chem. News*, Vol. XXXVI., p. 166).

A thallium anode, in water acidulated with sulphuric acid, is converted into the black trioxide by a current from two Bunsen's cells. (Watts's "Dictionary of Chemistry," Vol. VI., p. 1,082.)

The metal is reduced from its solutions, generally from the sulphate, either by a separate current or by simple immersion of zinc. When a current from two or three Grove's cells, with platinum electrodes, is passed through an acidulated solution of thallium sulphate, dissolved in its own weight of water, the metal is deposited upon the cathode in brilliant plates, and long needle shaped crystals stretching out towards the anode. The reduction is complete when hydrogen begins to escape at the cathode. (Crookes, Watts's "Dictionary of Chemistry," Vol. V., p. 743.)

For the electrolytic analysis of compounds of thallium see L. Schicht, *Chem. News*, Vol. XLII., p. 331.

Separation of Indium.—In. Atomic weight = 113·4. A cation. This metal being very costly, but little has been done with it in electro-chemistry. It is deposited from its solutions by simple immersion of zinc in them.

According to L. Schicht, indium is completely deposited as a bluish white metal at the cathode by a separate current, both from acid and from alkaline solutions. In the latter case the metal is very bright and firm. With solutions containing organic acids, indium is also deposited in a coherent state, with abundant escape of gas. (*Chem. News*, Vol. XLI., p. 280; also Vol. XLVII., p. 209.)

For the electrolytic analysis of compounds of indium see L. Schicht, *Chem. News*, Vol. XLII., p. 331.

Separation of Tin.—Sn. Atomic weight = 118. A cation. Very few solutions of tin are available for electrolysis; the chief are stannous chloride and the aqueous solutions of stannous and stannic fluoride.

M. H. Loewel added metallic tin to a solution of green crystallised chloride of chromium free from excess of acid, in a closed glass vessel, and boiled the mixture during about 10 or 12 minutes, and then allowed it to cool. During the heating the tin combined with the chlorine of some of the chromium salt, forming stannous chloride and chromous chloride; but during the cooling the action was reversed, the chromous chloride took chlorine from the stannous chloride, and metallic tin was deposited in the form of numerous small plates (*The Chemist*, Part VIII., May, 1854, p. 476).

Electrolysis of Stannous Fluoride.—$Sn.F_2$. Molecular weight = 156. I found that zinc, immersed in a solution of stannous fluoride, produced a flocculent precipitate, and evolved gas. In the same liquid, but containing free hydro-fluoric acid, crystals of silicon did not deposit tin by simple immersion. Fremy electrolysed fused fluoride of tin in a platinum vessel; it was easily decomposed; the deposited metal alloyed with and perforated the vessel in a few minutes (*The Chemist*, New Series, Vol. II., p. 548). I electrolysed a saturated nonacid solution of stannous fluoride by means of large platinum electrodes, and a current from 10 large Smee's cells; the conduction was sparing, a little oxygen was evolved at the anode, and long feathery crystals of tin were slowly formed upon the cathode. No gas appeared at the cathode, or solid deposit at the anode. By using only one Smee's cell the deposit of tin was white, and beautiful crystals of the metal soon reached across the liquid, and completed the metallic circuit by touching the anode.

Also by passing a current from six Grove's elements by means of platinum electrodes through a strong aqueous solution of *stannic* fluoride containing little or no free hydrofluoric acid a grey deposit of tin soon appeared on the cathode. The condution was free, much gas came from the anode, and heat was evolved in the liquid. The anode was not corroded, nor did it acquire any solid deposit.

Electrolysis of Stannous Chloride.—$Sn. Cl_2$. Molecular weight = 189. Electrolytic experiments for the separation of tin are usually made with solutions containing this salt. Magnesium deposits stannic acid and spongy tin from this solution (Commaille, *Chem. News*, Vol. XIV., p. 188). A "tin tree" is produced by immersing a spiral of zinc wire in ten to twenty ounces of water in which has been dissolved three drachms of this salt and ten drops of nitric acid, and allowing the arrangement to remain undisturbed. According to Böttger, sodium amalgam in contact with a concentrated solution of stannous chloride forms a viscid amalgam. Joule obtained a beautiful crystalline amalgam by using a separate current and making mercury the cathode in this liquid. I have observed that zinc and lead become tinned by simple immersion in a solution of the salt, but antimony, bismuth, platinum, gold, silver, copper, brass, German silver, nickel, iron, and tin do not. According to Raoult, gold or copper in contact with tin in a concentrated and boiling solution of stannous chloride receive a deposit of tin; but gold in contact with antimony, silver, copper, nickel, iron, or lead receives no such coating in either the hot or cold liquid. (*Chem. News*, Vol. XXVI., p. 240; and XXVII., p. 59. Also *Jour. Chem. Soc.*, Vol. X., p. 464.)

Zinc or iron previously coated with a film of metallic copper by simple immersion process acquire a deposit of tin by simple contact with a solution composed of one part of crystals of stannous chloride, two of water, and two of hydrochloric acid (C. Paul, *Jour. Chem. Soc.*, Vol. XI., p. 955). According to Roseleur, zinc and iron become tinned by simple immersion in a boiling hot solution composed of one part of fused stannous chloride, thirty of ammonium alum, and 2,000 of water; zinc also acquires a coating of tin by simple contact with a solution of one part of fused stannous chloride and five of pyrophosphate of sodium, dissolved in 300 parts of distilled water.

Copper, brass, and bronze become coated with tin by con-

Digitized by Google

tact during a few minutes with that metal in a boiling hot solution of peroxide of tin in caustic potash. F. Weil coats copper with tin by immersing it, in contact with zinc, in a solution formed by dissolving a salt of tin in a strong solution of caustic potash or soda, the liquid being at 50° to 100°C.; the deposit, however, contains zinc (*Chem. News*, Vol. XIII., p. 2). Dr. Hillier tins metals by immersing them in contact both with tin and zinc in a hot solution of one part of stannous chloride dissolved in 20 of water, to which has next been added one or two parts of caustic soda in 20 of water.

(TO BE CONTINUED.)

ELECTRICITY AND LIGHT.

BY JOHN T. SPRAGUE.

Electricity appears almost to realise for us one of the oldest and most striking of the representations of creative power, "Let there be light, and there was light." In most of our other sources of artificial light we appear to consume something which to the ordinary mind is converted into light. Here we have to all appearance light produced out of nothing, or as the next step from the ordinary unscientific reasoning to that of partial scientific enlightenment, *electricity converted into light*. A further advance in knowledge teaches us that—1. Electricity is not converted into light; 2, that no illuminating agent is so converted; 3, that light does not exist at all; that it is not *a thing*, but the *perception of an action*. The light is in the eye itself.

2. *Light is a Function of Energy*, and its study involves four considerations—1. The phenomena of its origin; 2, the mode of its transmission across space; 3, the nature of its perception; 4, the energy expended in these several processes. Each of these calls for and will be worth some little examination; but inasmuch as one of the great dangers of science is the acceptance of *words* (which are worthless except in so far as they convey a definite meaning) in the place of realities, it will be well to begin at an even earlier starting point. Electricity itself is a word which we all use, and which too many employ as though it were one of the old "words of power," the mere utterance of which is in itself sufficient to place the powers of nature under subjection. Yet what conflicting ideas exist as to what the word really means, and how few could give a really intelligible explanation of what they mean by it. That task we need not now attempt: but the latest of these magic names of science which we shall have much occasion to use calls for some particular consideration.

3. *What is Energy?* We have outgrown the intellectual stages at which men invented a specific fluid to answer such a question, and we recognise that we cannot say what anything *is*; we can only state the idea we form of it from its actions; we have no conception of energy except as a relation of matter and motion. It may be either expressed as the work capacity of matter in motion, or of matter under a stress capable of generating motion. But the essential feature of the modern scientific ideas as to energy is the recognition that it is uncreatable and indestructible. We can form no concrete idea of its nature; it is best conceived as *motion*, yet it is impossible even to conceive of motion apart from matter. It must therefore be recognised as an attribute of matter, yet distinct in its origin and nature, because it is transferable from one mass of matter to another, and even to that more intangible something, the *ether*. It is here, in fact, that the most usual explanations of energy fail us; we can form some sort of idea of energy in the form of work imparted to or effected by a moving mass of matter, but the imagination fails in realising the existence of vast stores of energy in mere space. It is a relief to accept the "ether," of which we know nothing, as almost representing the underlying essence of all things—the *substance* of metaphysics, endowed by the mathematician with the properties of an elastic solid, possessing none of the attributes of *matter* itself, while it is interchangeable with matter in the relations of energy.

4. *Kinetic energy* appreciable as work is the natural starting point of the endeavour to reach the unseen. A cricket ball struck by the bat gives us a perfect picture of the nature of energy, for it shows us an inert mass of matter suddenly endowed with motion, and with the capacity of doing work in consequence of that motion. We know that this capacity of doing work has been imparted to it from the muscles which moved the bat, that it is partly expended in friction of the air during its transit, and that if the motion is suddenly arrested some considerable results may be produced; in fact the ball has received, has transmitted, and has transferred that something which modern science calls "energy," and which is one of the most important elements out of which modern science is constructed.

5. *This energy can be definitely measured.* But here we should clearly recognise that, while professing to measure a thing which has after all no conceivable existence, we are merely measuring, not the thing itself, but an effect it produces. This is not an idle truism, for probably few people realise that it applies to all measurement, to all our knowledge. The most concrete idea—apparently—is that of matter, and the most apparent of our conceptions of matter is its *weight*, or in scientific terms, its mass. Yet, when we weigh a thing we are *not weighing matter itself*, we are merely measuring a *force exerted by it.* In ordinary cases we simply measure the mutual forces of attraction of the earth and the object.

6. *The most concrete measure of energy* is furnished by this very attraction, viz., the unit of mechanical work, the foot-pound, the energy imparted to a pound weight while moving through one foot of space under the force of the earth's attraction, or which must be expended in lifting that pound weight against the earth's attraction.

7. *Heat gives us another concrete unit* in the quantity of heat, which is now known to be an action of energy, necessary to raise one pound of water one degree of temperature. Here again, however, we have to recognise that we cannot measure a thing itself, but only its effects. We speak of a *quantity of heat*, but we never measure *heat itself;* we measure either a temperature effect, variable in every separate substance, and necessary to be ascertained by experiment, or we measure an expansion effect variable also in every substance except in pure gases.

8. *The correlation of the forces*, the knowledge of which is the greatest achievement of this age, as far as pure science is concerned, because it is the starting point of progress of discovery in all directions, means that many actions which used to be attributed to special fluids or *forces* are merely different manifestations of *energy*. It follows, therefore, that one unit of energy can represent all these actions; that is to say, that just as a quantity of heat contained in a mass of red hot iron can be expressed in terms of the number of pounds of water it will raise 1° F. in temperature when the relations are ascertained, so can it equally be expressed in foot-pounds of mechanical work once the inter-relation of these actions of energy is ascertained.

9. *The action of heat on a pure gas* is the most apparent evidence of this relation, although not the one by which it is usually illustrated. We can impart heat to a gas in two ways. 1. The gas being enclosed in a rigid vessel and heated, a certain number of degrees exhibits that heat in the form of temperature, just as water or iron does; this is the *heat of constant volume.* Under these circumstances a force is also developed—a pressure or tendency to expand. 2. The gas may be allowed to expand freely while heating, and will now absorb what is called the *heat of constant pressure.* Now if we pass the gas into a calorimeter we shall find that the heat of this second case is the greater by a measureable quantity. But as the same quantity of gas is at the same temperature in each case, how has this excess of heat been disposed of so as not to be apparent, and yet capable of being recovered? Something else has been done besides heating the gas; the art of expansion involved the lifting a column of the atmosphere, and this work can be measured in foot-pounds. This work therefore represents the energy corresponding to the difference of the two heats. Various experimental conversions have been made resulting in the two figures of 772 foot-pounds and

Digitized by Google

1lb. 1° F. of water, which are received as the "mechanical equivalent of heat;" that is to say, the same quantity of energy will appear as either of the two forms, and 1lb. of water falling 772 feet would be heated 1° if it could be stopped so as to retain in itself the whole energy of the earth's attraction.

10. *Potential energy* is more difficult to conceive than kinetic, but our cricket ball may furnish some ideas. When it is flying through space it is not doing work, except as friction in the air; but it has the capacity to do work, and this friction work is a gradual exertion of that capacity. Its motion at each instant is therefore the measure of its remaining capacity, and is in fact the consequence of and the evidence of the energy *potential* or latent in the ball. Now the unscientific mind would imagine that this energy was created by the striker, the production of his will; but science knows that the player no more created the energy than the bat did. The player in exerting his muscles burnt away a portion of their material or consumed some of the substance stored in his blood and derived from his food; in fact, he corresponds in function to a steam engine and boiler fed with coal. We come then to the result that he simply transferred *potential* energy to the ball, converting it first into *kinetic* energy or mechanical work in his muscles. The food itself simply stored up energy derived from the sun's beams, because the process of vegetable life is a continual *unburning* of hydrogen in water and carbon in carbonic acid, and the setting free of oxygen in the air, a process which requires an equivalent of energy to be imparted to the atoms, which energy they give up on their re-union, whether in the lungs and muscles of the cricket player or the boiler of the steam-engine.

ON MECHANICAL DYNAMOMETERS.

BY GISBERT KAPP.

(CONTINUED FROM PAGE 539, VOL. XII.)

Another very ingenious contrivance depending upon gravity is H. Darwin's dead-weight rotary dynamometer,* which is

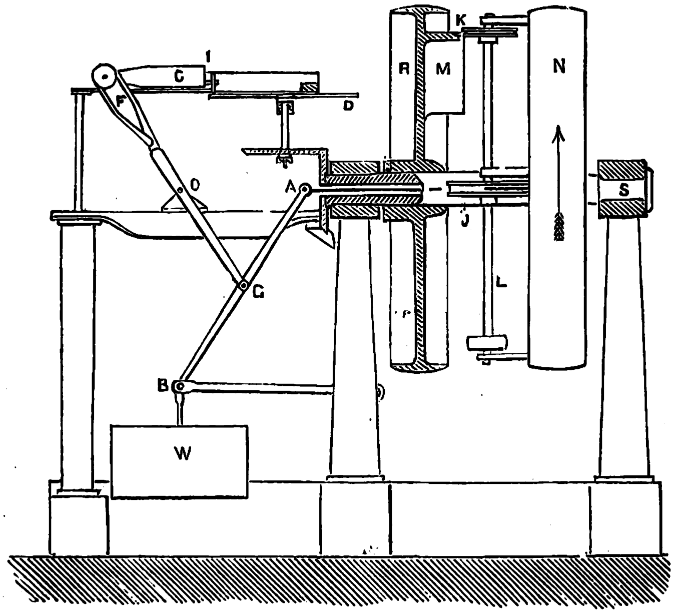

FIG. 27.—Darwin's Dead-Weight Rotary Dynamometer.

shown in elevation in Fig. 27. The power is received on pulley N (which is keyed fast on the shaft S), and is transmitted to the machine under test by a belt from pulley R. The latter is loose on the shaft, but is carried round by a chain, one end of which is attached to the sector M, whilst the other end is wound on to the small wheel K. This wheel is keyed to a spindle L L, supported in bearings which are fastened to pulley N, and is thus forced to revolve with that pulley. Another wheel, J, is keyed to about the middle of shaft L, and enters partly into a slot cut out in shaft S. The object of this is to bring a chain, which is wound on wheel J, exactly into the centre of the shaft, where it is fastened to a flat bar, passing through a central hole, and ending with a swivel joint at A. A G B is a lever pivoted at G, and carrying at B a weight, W, which tends to pull the bar out from the shaft, thus uncoiling the chain wound on T, and coiling more chain on to wheel K, the two chains being wound in opposite directions. Conversely, a twisting strain or torque between the pulleys N and R will result in partly uncoiling the chain wound on K, and coiling more on to J, whereby the bar is drawn further into the shaft, and the weight is raised. The fulcrum G of the lever A B is not fixed, but is formed by the lower end of another lever G O F, which is pivoted in a fixed point, O, and the upper end of which is provided with a fork, F, by which the position of the integrating wheel T is controlled. D D is the disc driven by bevel gear at a speed proportional to that of the pulleys, and C is a counter by which the mechanical energy transmitted during any given time is recorded. One important feature of this dynamometer is that the horizontal displacement of the integrating wheel is exactly proportional to the torque between the two pulleys, and that therefore the integration performed by the recording apparatus is mathematically correct. To prove this let, in Fig. 28, A P represent the pull on the bar, that is, a force proportional to the torque transmitted; let B W represent the weight which is attached to the lower end

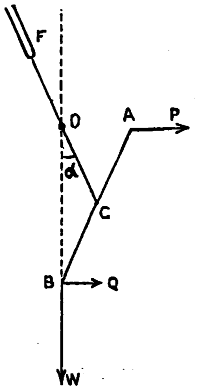

FIG. 28.

of the lever A G B, and O G the lower arm of the lever, which by a fork, F, controls the position of the integrating wheel. The displacement of this wheel is of course proportional to tang α, α being the angle to which the lever O G is pulled away from the vertical by the force A P. If O G = A G = B G, the three points A, O and B must be on a circle described from G as a centre, and if A be guided horizontally and B vertically the direction of both forces P and W must be through the fixed fulcrum O, and their magnitude must be as the corresponding sides of the rectangular triangle A O B inscribed into the semi-circle. We would thus have the equation

$$P = W \text{ tang } \alpha.$$

There is, however, one objection which might be raised against this reasoning, viz., that the guiding of the points A and B in a horizontal and vertical line respectively might introduce certain reacting forces (in a vertical direction on A and in a horizontal direction on B) which would invalidate the above equation. It is easy to show that these points would move in straight lines, even if not forced to do so by guides, or, in other words, that the guides do not react on these points. To prove this, assume that on the long radius rod guiding B (Fig. 27) in an arc, which for a small vertical displacement can without error be substituted for its tangent, there were a reaction Q in a horizontal direction. Replacing the forces P, W and Q by their components taken parallel and vertical to A B, we find one condition of equilibrium for this lever to be

$$P \cos \alpha = W \sin \alpha + Q \cos \alpha \quad . \quad . \quad . \quad . \quad (1)$$

Let T represent the total pull on the second lever in the direction O G, and substitute for it also its components, we

* *Proceedings* Institution of Mechanical Engineers, July, 1876.

Digitized by Google

find that the vertical component is

$$T \sin 2\alpha,$$

and the parallel

$$T \cos 2\alpha.$$

Since both arms of the lever A B are equal, the reaction in its fulcrum must be twice as great as the force applied on either end, that is

$$2 P \cos \alpha = T \sin 2\alpha \quad . \quad . \quad . \quad . \quad (2)$$

The components taken parallel to A B of the various forces acting in A, G and B must be in equilibrium amongst themselves, which gives the equation

$$P \sin \alpha + T \cos 2\alpha + Q \sin \alpha = W \cos \alpha,$$

which, combined with (2), gives

$$P + Q\, tg^2 \alpha = W\, tg\, \alpha.$$

But from equation (1) it follows that

$$P - Q = W\, tg\, \alpha,$$

and it is evident that these equations can only coexist if $Q = 0$.

In the same way it can be proved that a guide in A cannot produce any vertical pressure on that point; in fact, if the lower end of the lever is guided in a vertical line the upper end will of itself move along a horizontal, and thus make a second guide unnecessary. Having now proved that the equation

$$P = W\, tg\, \alpha$$

is rigorously correct, and remembering that the displacement of the integrating wheel from the centre of the disc is by reason of the sliding fork-attachment also proportional to $tg\, \alpha$, we find that

$$P = cr$$

where P can now be taken to represent the torque or power transmitted to the machine under test, c is a constant, and r is the radial displacement of the integrating wheel on the face of the disc D D.

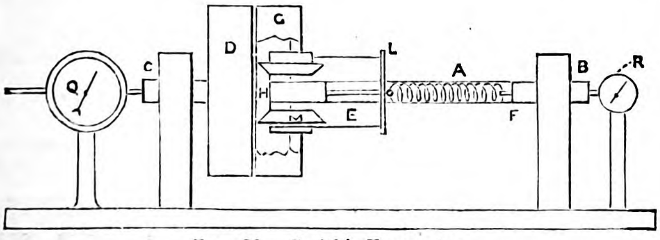

FIG. 29.—Smith's Ergometer.

Although this instrument does not seem to have met with much practical success, it forms one of the most interesting and ingenious contrivances for integrating energy transmitted, and the peculiar arrangement of levers just described deserves to be more widely known, as it may prove useful for some other application.

A somewhat similar instrument, but without integrating apparatus, is Emmerson's transmission dynamometer, intended for use in factories for measuring, or rather indicating, at any moment the amount of power flowing from the main shaft into that particular tool to which it is fitted. In this case the instrument takes the place of the usual overhead motion, and consists of a short countershaft provided with two pulleys, of which one is fast and drives on to the tool, the other is loose and connected by a belt with the main shaft. A system of bell-crank levers and sliding pieces (corresponding in Darwin's dynamometer to the chains, wheels and sliding bar) connect the loose pulley to a hub sliding on a fast feather on the shaft and transmitting to it the rotation of that pulley, whilst displacing at the same time the hub longitudinally on the shaft to a greater or lesser amount, according to the power transmitted. This displacement is partly resisted by a collar, bell-cranks, tension-rod and weight swinging on a radial arm and in front of a quadrant, on which, by means of a suitable scale, the power transmitted can at any moment be read off. The scale can of course be only correct for one definite speed of the main shaft, but since that is very nearly a constant speed in most factories the dynamometer overhead motion fitted to each tool can be calibrated for that constant speed and would thus show at a glance the power absorbed by each tool.

Fig. 29 shows F. T. Smith's transmission ergometer. This dynamometer has as usual two pulleys, D fast and G loose. To the former is fixed a bevel wheel, H, and to the latter are attached bearings for two other bevel wheels, K and M, both in gear with H, and each provided with a drum upon which a steel cord is coiled, the direction being opposite on the two drums. The cords are attached to a cross-bar, L, passing through the shaft C B, which is tubular at each end, and link-shaped between E F, and the centre of this cross-bar is fastened to a spiral spring A, which is elongated in proportion to the twisting couple which is being transmitted from D to G by means of the bevel gear. The speed is taken from a speed indicator, R, and the tension of the spring—that is the torque transmitted—is made known by the pointer of the dial Q, which is worked by a rod passing through the hollow shaft. Since the spring is placed into the centre of the shaft it is unaffected by centrifugal force. Fig. 30 is a full view of the apparatus as applied to a magneto machine, and the author is indebted to the inventor for the loan of this drawing. Mr. Smith has greatly improved existing and also invented new appliances for use in dynamometric tests. As a detailed account of these will be found in a little pamphlet* only recently published, it will not be necessary to describe these appliances here at length, and we must be content to merely mention a few. One of these is the testing of a small electromotor by suspending its field-magnets on centres, and measuring by a lever and weight or spring the power required to keep the field-magnets from revolving. This plan was first used in 1881 on some Trouvé motors. Another is an improvement in White's dynamometer, whereby a continuous diagram and record of the power transmitted is obtained, and also deserves mention. Mr. Smith has devised several integrating instruments. In one of these the volume of water delivered by a little pump is made to be in direct proportion with the work passing through the dynamometer. The pump is driven at the same or a proportional speed to the dynamometer, but its stroke is variable by means of a link and sliding block. The position of the block being controlled in accordance with the torque transmitted, the volume of water delivered by the pump is an exact measure of the energy. Another instrument is the ratchet and sink integrator, organically the same as the hydraulic integrator, but instead of a double acting pump two ratchet wheels are employed. The usual integrating wheel already often mentioned in these articles has been improved by Mr. Smith so as to move over the face of the disc with practically no friction. This is attained by providing the rim of the integrating wheel with a number of small rollers, and thus changing what formerly was a scraping movement into smooth rolling. To indicate the speed Mr. Smith employs a modification of Ramsbottom's well-known velocimeter, substituting mercury and tinted water for oil, or a telephonic arrangement depending upon the isochronic movement of two wheels, one driven by the machine, the other by hand. This method is especially recommended for testing small motors. The power necessary to drive an ordinary speed counter or speed indicator, although small enough in itself, is yet sufficiently large to be felt by a small motor. In these cases the speed can be found either by employing Mr. Smith's telephonic arrangement or by a phonetic wheel, or by a very light train of clockwork driven by an endless fine cotton thread from a small grooved wheel on the spindle of the motor to a large wheel on the quickest shaft of the clockwork, a plan which the author has found to answer very well. If the frame of the clockwork be pivoted on centres with a light spring to pull it against the driving thread there will be no loss of speed from slipping, and yet the power to drive the clockwork is so small that it can be neglected even if testing very small motors.

THE PROTECTION OF SUBMARINE TELEGRAPH CABLES.

The following is the English translation of a despatch, signed at Paris on March 14 last, from Lord Lyons to the Secretary of State for Foreign Affairs, on the subject of the Protection of Submarine Telegraph Cables :—

Viscount Lyons to Earl Granville.—(Received March 22.)

(Extract.) Paris, March 21, 1884.

I have the honour to transmit herewith to your lordship, in original, the Convention for the protection of submarine cables, signed on the 14th instant by myself, on the part of Great Britain, and by the Plenipotentiaries of the twenty-five other States parties to it, on behalf of their respective Governments.

I transmit also the *procès-verbal* of signature, which was signed by the other Plenipotentiaries and myself on the 14th March.

Your lordship will observe that the *procès-verbal* contains a provision that the exchange of the ratifications of the Convention shall be made through the French Government.

(Enclosure I.)

Her Majesty the Queen of the United Kingdom of Great Britain and Ireland, Empress of India, His Majesty the German Emperor, King of Prussia, His Excellency the President of the Argentine Confederation, His Majesty the Emperor of Austria, King of Bohemia, &c., and Apostolic King of Hungary, His Majesty the King of the Belgians, His Majesty the Emperor of Brazil, His Excellency the President of the Republic of Costa Rica, His Majesty the King of Denmark, His Excellency the President of the Dominician Republic, His Majesty the King of Spain, His Excellency the President of the United States of America, His Excellency the President of the United States of Colombia, His Excellency the President of the French Republic, His Excellency the President of the Republic of Guatemala, His Majesty the King of the Hellenes, His Majesty the King of Italy, His Majesty the Emperor of the Ottomans, His Majesty the King of the Netherlands, Grand Duke of Luxemburg, His Majesty the Shah of Persia, His Majesty the King of Portugal and the Algarves, His Majesty the King of Roumania, His Majesty the Emperor of all the Russias, His Excellency the President of the Republic of Salvador, His Majesty the King of Servia, His Majesty the King of Sweden and of Norway, and His Excellency the President of the Oriental Republic of the Uruguay, being desirous to secure the preservation of telegraphic communications made by means of submarine cables, have resolved to conclude a Convention for this purpose, and have named for their Plenipotentiaries, that is to say :

Her Majesty the Queen of the United Kingdom of Great Britain and Ireland, Empress of India : his Excellency the Right Honourable Richard Bickerton Pemell, Viscount Lyons, a Peer of the United Kingdom of Great Britain and Ireland, Member of Her Britannic Majesty's Privy Council, Her Ambassador Extraordinary and Plenipotentiary to the Government of the French Republic, &c., &c. ;

His Majesty the Emperor of Germany, King of Prussia : his Highness Prince Chlodwig Charles Victor de Hohenlohe-Schillingfürst, Prince de Ratibor and Corvey, Grand Chamberlain of the Crown of Bavaria, his Ambassador Extraordinary and Plenipotentiary to the Government of the French Republic, &c., &c.;

His Excellency the President of the Argentine Confederation : M. Balcarce, Envoy Extraordinary and Minister Plenipotentiary of the Confederation at Paris, &c., &c.;

His Majesty the Emperor of Austria, King of Bohemia, &c., and Apostolic King of Hungary : his Excellency Count Ladislas Hoyos, Actual Privy Councillor, his Ambassador Extraordinary and Plenipotentiary to the Government of the French Republic, &c., &c.;

His Majesty the King of the Belgians : Baron Beyens, his Envy Extraordinary and Minister Plenipotentiary at Paris, &c., &c. ; and M. Léopold Orban, Envoy Extraordinary and Minister Plenipotentiary, Political Director-General in the Department for Foreign Affairs of Belgium, &c., &c. ;

His Majesty the Emperor of Brazil : M. d'Araujo, Baron d'Itajuba, Brazilian Chargé d'Affaires at Paris, &c., &c. ;

His Excellency the President of the Republic of Costa Rica : M. Léon Somzée, Secretary of the Costa Rican Legation at Paris, &c., &c. ;

His Majesty the King of Denmark : Count Moltke-Hvitfeldt, his Envoy Extraordinary and Minister Plenipotentiary at Paris, &c., &c. ;

His Excellency the President of the Dominican Republic : Baron de Almeda, Minister Plenipotentiary of the Dominican Republic at Paris, &c., &c. ;

His Majesty the King of Spain : His Excellency M. Manuel Silvela de le Vielleuse, Permanent Senator, Member of the Spanish Academy, his Ambassador Extraordinary and Plenipotentiary to the Government of the French Republic, &c., &c. ;

His Excellency the President of the United States of America : Mr. L. P. Morton, Envoy Extraordinary and Minister Plenipotentiary of the United States of America at Paris, &c., &c., and Mr. Vignaud, Secretary of the Legation of the United States of America at Paris, &c., &c. ;

His Excellency the President of the United States of Colombia : Dr. José G. Triana, Consul-General of the United States of Colombia at Paris, &c., &c. ;

His Excellency the President of the French Republic : M. Jules Ferry, Deputy, President of the Council, Minister for Foreign Affairs, &c., &c., and M. Adolphe Cochery, Deputy, Minister of Posts and Telegraphs, &c., &c. ;

His Excellency the President of the Republic of Guatemala : M. Crisanto Medina, Envoy Extraordinary and Minister Plenipotentiary of the Republic of Guatemala at Paris, &c., &c. ;

His Majesty the King of the Hellenes : Prince Maurocordato, his Envoy Extraordinary and Minister Plenipotentiary at Paris, &c., &c. ;

His Majesty the King of Italy : his Excellency General Count Menabrea, Marquis de Valdora, his Ambassador Extraordinary and Plenipotentiary to the Covernment of the French Republic, &c., &c. ;

His Majesty the Emperor of the Ottomans : his Excellency Essad Pasha, his Ambassador Extraordinary and Plenipotentiary to the Government of the French Republic, &c., &c. ;

His Majesty the King of the Netherlands : Grand Duke of Luxemburg, Baron de Zuylen de Nyevelt, his Envoy Extraordinary and Minister Plenipotentiary at Paris, &c., &c. ;

His Majesty the Shah of Persia : General Nazare Aga, his Envoy Extraordinary and Minister Plenipotentiary at Paris, &c., &c. ;

His Majesty the King of Portugal and the Algarves : M. d'Azevedo, Portuguese Chargé d'Affaires at Paris, &c., &c. ;

His Majesty the King of Roumania : M. Odobesco, Roumanian Chargé d'Affaires *ad interim* at Paris, &c., &c. ;

His Majesty the Emperor of all the Russias : his Excellency Aide-de-camp General Prince Nicolas Orloff, his Ambassador Extraordinary and Plenipotentiary to the Government of the French Republic, &c., &c. ;

His Excellency the President of the Republic of Salvador : M. Torrès-Caïcedo, Envoy Extraordinary and Minister Plenipotentiary of the Republic of Salvador at Paris, &c., &c. ;

His Majesty the King of Servia : M. Marinovitch, his Envoy Extraordinary and Minister Plenipotentiary at Paris, &c., &c. ;

His Majesty the King of Sweden and of Norway : M. Sibbern, his Envoy Extraordinary and Minister Plenipotentiary at Paris, &c., &c. ;

His Excellency the President of the Oriental Republic of the Uruguay : Colonel Diaz, Envoy Extraordinary and Minister Plenipotentiary of the Oriental Republic of the Uruguay at Paris, &c., &c. ;

Who, after having exchanged their full powers, found in good and due form, have agreed upon the following Articles :—

ARTICLE I.—The present Convention applies outside territorial waters to all legally established cables landed on the territories, colonies, or possessions of one or more of the high contracting parties.

ARTICLE II.—It is a punishable offence to break or injure a submarine cable, wilfully or by culpable negligence, so as to interrupt or obstruct telegraphic communication, either wholly or partially, such punishment being without prejudice to any civil action for damages.

This provision does not apply to cases where those who break or injure a cable do so with the lawful object of saving their lives or their ship, after they have taken every necessary precaution to avoid so breaking or injuring the cable.

ARTICLE III.—The high contracting parties undertake that, on granting a concession for landing a submarine cable, they will insist upon proper measures of safety being taken, both as regards the track of the cable and its dimensions.

ARTICLE IV.—The owner of a cable who, on laying or repairing his own cable, breaks or injures another cable, must bear the cost of repairing the breakage or injury, without prejudice to the application, if need be, of Article II. of the present Convention.

ARTICLE V.—Vessels engaged in laying or repairing submarine cables shall conform to the regulations as to signals which have been, or may be, adopted by mutual agreement among the high contracting parties, with the view of preventing collisions at sea.

When a ship engaged in repairing a cable exhibits the said signals, other vessels which see them, or are able to see them, shall withdraw to or keep beyond a distance of 1 nautical mile at least from the ship in question, so as not to interfere with her operations.

Fishing gear and nets shall be kept at the same distance.

Nevertheless, fishing-vessels which see or are able to see a telegraph ship exhibiting the said signals, shall be allowed a period of twenty-four hours at most within which to obey the notice so given, during which time she shall not be interfered with in any way.

The operations of the telegraph ships shall be completed as quickly as possible.

ARTICLE VI.—Vessels which see, or are able to see, the buoys showing the position of a cable when the latter is being laid, is out of order, or is broken, shall keep beyond a distance of one-quarter of a nautical mile at least from the said buoys.

Fishing nets and gear shall be kept at the same distance.

ARTICLE VII.—Owners of ships or vessels who can prove that they have sacrificed an anchor, a net, or other fishing gear in order to avoid injuring a submarine cable shall receive compensation from the owner of the cable.

To be entitled to such compensation, a statement, supported by the evidence of the crew, must, whenever possible, be drawn up immediately after the occurrence ; and the master must, within twenty-four hours after arriving at his destination, or on next putting into a port, make a declaration to the proper authorities.

The latter shall communicate the information to the consular authorities of the country to which the owner of the cable belongs.

ARTICLE VIII.—The tribunals competent to take cognisance of infractions of the present Convention are those of the country to which the vessel on board of which the offence was committed belongs.

It is, moreover, understood that, in cases where the provisions in the previous paragraph cannot apply, offences against the present Convention

Digitized by Google

will be dealt with in each of the contracting States in accordance, so far as the subjects and citizens of those States respectively are concerned, with the general rules of competence prescribed by the municipal laws of that State, or by international treaties.

ARTICLE IX.—Prosecutions for infractions provided against by Articles II., V., and VI. of the present Convention shall be instituted by the State, or in its name.

ARTICLE X.—Offences against the present Convention may be verified by all means of proof allowed by the legislation of the country of the Court. When the officers commanding the ships of war, or ships specially commissioned for the purpose by one of the high contracting parties, have reason to believe that an infraction of the measures provided for in the present Convention has been committed by a vessel other than a vessel of war, they may demand from the captain or master the production of the official documents proving the nationality of the said vessel. The fact of such document having been exhibited shall then be endorsed upon it immediately. Further, formal statements of the facts of any offence may be prepared by the said officers, whatever may be the nationality of the vessel on board of which the offence has been committed. These formal statements shall be drawn up in the form and in the language used in the country to which the officer making them belongs; they may be considered, in the country where they are adduced, as evidence in accordance with the laws of that country. The accused and the witnesses shall have the right to add, or to have added, thereto, in their own language, any explanations they may consider useful. These declarations shall be duly signed.

ARTICLE XI.—The proceedings and trial in cases of infraction of the provisions of the present Convention shall take place as summarily as the laws and regulations in force will permit.

ARTICLE XII.—The high contracting parties engage to take or to propose to their respective Legislatures the necessary measures for insuring the execution of the present Convention, and especially for punishing, by either fine or imprisonment, or both, those who contravene the provisions of Articles II., V., and VI.

ARTICLE XIII.—The high contracting parties will communicate to each other laws already made, or which may hereafter be made, in their respective countries, relating to the object of the present Convention.

ARTICLE XIV.—States which have not signed the present Convention may adhere to it on making a request to that effect. This adhesion shall be notified diplomatically to the Government of the French Republic, and by the latter to the other Signatory Powers.

ARTICLE XV.—It is understood that the stipulations of the present Convention do not in any way restrict the freedom of action of belligerents.

ARTICLE XVI.—The present Convention shall be brought into force on a day to be agreed upon by the high contracting Powers.

It shall remain in force for five years from that day, and unless any of the high contracting parties have announced, twelve months before the expiration of the said period of five years, its intention to terminate its operation, it shall continue in force for a period of one year, and so on from year to year.

If one of the Signatory Powers denounce the Convention, such denunciation shall have effect only as regards that Power.

ARTICLE XVII.—The present Convention shall be ratified, and the ratifications exchanged at Paris with as little delay as possible, and, at the latest, at the expiration of a year.

In witness whereof the respective Plenipotentiaries have signed the same, and have affixed thereto their seals.

Done in twenty-six copies, at Paris, the 14th day of March, 1884.

ADDITIONAL ARTICLE.—The stipulations of the Convention concluded under to-day's date for the protection of submarine cables shall be applicable, in conformity with Article I., to the Colonies and possessions of Her Britannic Majesty, with the exception of those hereinafter mentioned, namely:—Canada, Newfoundland, the Cape, Natal, New South Wales, Victoria Queensland, Tasmania, South Australia, Western Australia, New Zealand. Provided always that the stipulations of the said Convention shall be applicable to any of the above-named Colonies or possessions on whose behalf notice to that effect shall have been given by Her Britannic Majesty's representative at Paris to the French Minister for Foreign Affairs.

Each of the above-named Colonies or possessions which may have acceded to the said Convention shall be at liberty to withdraw from it in the same manner as the Powers parties to it. In the event of any of the said Colonies or possessions desiring to withdraw from the Convention, a notification to that effect shall be made by Her Britannic Majesty's Representative at Paris to the French Minister for Foreign Affairs.

(Enclosure II.)

After having communicated their full powers, the Plenipotentiaries collated the texts of the Convention which had been prepared in a number equal to that of the contracting States, and all these documents having been found in good and proper form, the Plenipotentiaries affixed thereto their signatures and the seal of their arms.

On signing the Convention, his Excellency Lord LYONS made the following declaration in the name of his Government:—

"Her Majesty's Government takes Article XV. to mean that in time of war, a belligerent, who is Signatory to the Convention, will be free to act, with respect to submarine cables, as if the Convention did not exist."

Formal note was taken of this declaration on the part of his Excellency the Ambassador of Great Britain.

M. LÉOPOLD ORBAN read the following declaration in the name of the Belgian Government:—

"The Belgian Government, through its delegate at the Conference, has maintained that the Convention has no effect on the rights of belligerent Powers; these rights would be, after signing, neither more nor less extended than they are at present. The reference inserted in Article XV., though absolutely useless in the view of the Belgian Government, would not justify it in refusing to join in an object the importance of which was beyond dispute."

Formal note was taken of this declaration of M. Léopold Orban.

Baron de ZUYLEN DE NYEVELT stated that the Netherlands Government, in signing the Convention, could undertake to accede at present only as regards the mother country. It reserved to itself the power to accede later to this Convention for the whole or for part of its colonies or possessions.

Formal note was taken of this declaration of the Minister of the Netherlands.

The Minister of SWEDEN and NORWAY stated that his instructions require him to reserve, in signing the Convention, the subsequent approval of the legislatures of the United Kingdoms.

The PRESIDENT took formal note of this declaration of the Minister of Sweden and Norway, while observing further that the reservation for the fulfilment of the formalities required by the different constitutions, before exchanging the ratifications of the Convention, was the right of all the contracting States.

Taking into consideration the large number of the contracting parties, and following the method of proceeding already adopted at the time of the ratification of the treaties relative to the redemption of the Sound dues and Scheldt tolls, of the Telegraph Convention at Paris, and of the Metre Convention, it was agreed, on the motion of the President, that the exchange of ratifications for the protection of submarine cables should be effected through the Government of the French Republic.

The Plenipotentiaries decided further that the document which had just been signed should be brought to the cognisance of all the non-Signatory States, which should be invited to take advantage of the power of accession which is reserved to them by Article XIV. of the Convention.

It was agreed that this communication should be left to the care of the French Minister for Foreign Affairs. The Government of the French Republic would likewise receive notifications of accession which might come in before the date fixed for the Convention to come into force.

The present minutes, drawn up during the sitting, having been read and approved, the Conference separated at three o'clock.

TELEGRAPHS AND NEWS AGENCIES.

It is not surprising that the result of the action brought against the Eastern Telegraph Company by the Central News has given little satisfaction to the newspapers. To begin with, they had expected a great scandal; secondly, they had hoped that an injustice alleged to have been done to one of their emissaries would be severely punished; and lastly, they had persuaded themselves that telegrams sent by their accredited correspondents would be declared inviolable. On all these points the newspapers have been rudely undeceived, and, we venture to add, disappointed. The scandal, what there was of it, got fixed on the other shoulders; the wrong, if there was any, was not committed by the defendants; and as to the inviolability of telegrams, their violation has been strongly upheld on grounds of public policy. The lesson taught by this trial will be valuable to newspaper correspondents and to news agencies for all future time; but they have not taken it very kindly, and it is evident that a quite different lesson was expected—one which the telegraph companies would have to take to heart, not their customers.

But when all due allowance has been made for these natural disappointments there still remains a good deal that is altogether unreasonable, and even absurd, in the comments which newspapers have indulged in on this case. Nothwithstanding the proved innocence of the defendants on the one hand, and the proved indiscretion—to use no stronger phrase—of the plaintiffs, the Press have almost uniformly treated the verdict as if it had been given on a technical issue, instead of being, as it actually was, decided upon the undisputed facts revealed in the course of the trial. We are unable to admit even, that had the defendants' case been known beforehand the plaintiffs would not have proceeded with theirs; for when it did become known the trial was pushed on all the same, a circumstance which lent some colour to the plea of the defendants that the action was a spiteful one, and deserved the defeat it sustained in open court. It is impossible to acquit the newspapers of partiality in this respect; if anybody but a news agent had been guilty of obtaining evidence in the manner confessed to by the plaintiffs, and of employing testimony which a little careful inquiry would have shown to be false, the newspapers would have reserved their virtuous indignation for him, and not be now wasting it on people who were proved to have committed no wrong whatever, either moral or legal.

Now we make bold to demur to the proposition that any wrong was done the Central News Company, and we take our stand on public grounds. One of the newspapers above referred to puts it that Mr. Burleigh's telegram having being forwarded in the interests of the public, the public suffered through its being forestalled. This is mere cant; we have too high an opinion of the business capacity of news agencies to suppose that they labour for the public, and if we had any doubt on this point it would be removed by the contention put forward at the trial. For what does it really amount to? Why, that a newspaper correspondent may block the wires as long as he pleases, and thus *prevent* the public receiving any news until he chooses to leave off writing. There is another contention equally extravagant, and more openly avowed than the one just mentioned, namely, that although the news which is being transmitted is public property all along the route it must not be made use of until the newspaper agent's telegram has dragged its weary length to its destination. This disposes of the affectation of acting for the public good. The public wants early information, and it is a matter of indifference to them who sends or who brings the information.

But, say the friends of the plaintiffs, the indiscretion of the agent in sending a telegram of such inordinate length does not justify its being "milked" on the way. To this we reply, again on public grounds, that milking was perfectly justified in the circumstances. It is by no means certain that it occurred; to assume that it did occur would be to assert that the news of a great victory well known at Kassassin would not travel over the military wire between that place and Ismailia independently of Mr. Burleigh, an assertion which can only provoke a smile among people who know anything of telegraphy during exciting times, especially where military wires are concerned. But even admitting that the only information available was that obtained from the heroic, but effusive, newspaper correspondent, can it be contended that the military authorities—that is to say, the real servants of the public, whose business it was to obtain information—would wilfully shut their eyes to the Burleigh telegram because it happened to be addressed to a news agency in London? If the sender imagined that his

Digitized by Google

telegram would be treated as an inviolable secret, all we can say is that his imagination was as defective as his judgment. Similarly as regards the Eastern Telegraph Company's representative at Alexandria. It has been argued that he knew, or ought to have known, that a Press message was being sent through one of the company's cables, and that he ought, therefore, to have refrained from sending any news over the second cable lest the news going over the other should be anticipated. That argument would apply equally to any private individual in Alexandria where the news was published in the streets; and we are landed at the preposterous conclusion that no matter what number of cables were available, or how wide soever the news might be known, everything was to be kept idle in order that Mr. Burleigh's telegram might arrive at its destination first. We should like to have the opinion of the Post Office authorities on this point of telegraphic ethics. Suppose, for example, the first "result" of the Derby—which after all is not a contest of such national importance as a battle in which English troops are engaged—were handed in on a form containing four or five hundred words. Would it be the first to arrive in Fleet-street? We suspect not. But be that as it may it is plain that, although under no circumstances can the war telegram of a newspaper correspondent passing over military wires be considered inviolable, the particular telegram in question would have beaten its competitors had it been brief. There is far too much disposition on the part of newspaper correspondents to treat the telegraph as if it were a racecourse; but if they expect to win they should at least take care not to handicap their horses too heavily. The further question whether the agents of a telegraph company may join in the race is one for their consideration alone. They may do so on public grounds or for private reasons of their own; but whatever their reasons, so long as they do not appropriate it directly from what is exclusively passing over their lines, they are perfectly within their rights to transmit public news on their own account.

CORRESPONDENCE.

OVERHEAD TELEGRAPH AND TELEPHONE WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The correspondence now being published in your paper between "Mos Legem Regit" and "Telephonist" is of great interest to anybody practically acquainted with the London Exchange system. "Mos Legem Regit" says in his last: "In some of the earlier London Exchanges there appears good evidence of careful design to prevent the effects of induction, because the wires were carefully separated all the way to the switch-boards. On the other hand, the wires leading into the more recent exchanges are tied closely together in bundles, although the insulation on the wires is less adapted to resist damp. Nothing but some half-fledged theory can have originated this bold and reckless deviation from the former practice."

Well, what *can* you expect from half-fledged electricians but half-fledged theories? The men who designed the earlier exchanges *were* electricians and engineers, not of the class which the low salaries of the company now buy into their service. The primary reason for making the wires into bundles and jamming them into troughs was that in the old system the wires being strained on cleats about half an inch from the ceiling they became so coated with dust as to be twice their natural size, so that on the room shaking or the least wind the dust used to come down in clouds on the heads of the lady operators, much to their disgust. The secondary, or what should be a secondary, reason with a rich company was the cost of putting them up.

But somehow or other no one thought of cleaning them; in fact, they were not dusted more than once or twice from the time the company united until they were taken down, which was about a year ago.

Then as to induction. Is a waterpipe earth connection good enough for an exchange of 500 subscribers? In fact, in some of the subscribers' offices the connections are simply disgraceful, the wires being merely trussed together without the least attempt at a soldered joint.

I am inclined to think that a good deal of this so-called induction is greatly due to bad earth.

In one case, in one of the City call rooms, there used to be four instruments in communication with four different exchanges. Two of these lines were run together in a cable along with several others for some distance, then separated; the other two ran in a totally different direction not only to themselves but to the other two, and yet conversation was quite audible between any two lines. Surely this was not induction.

Then there is a great deal of unnecessary talking on trunk lines, owing to so many different systems being in operation in the several exchanges, which greatly adds to the Babel.

But while outsiders are trying to ferret out the mysteries of induction, what is the company doing to lessen the effects? Practically nothing, in a scientific way. The least they might do is to separate their trunk lines from subscribers' lines, and pay a little more attention to the insulation of them, as the effects of induction are always felt more on trunk lines than any others, they being the longest, as there are very few lines of any great length belonging to subscribers. These and many other faults, which are nothing in themselves, when blended together go to make up this *bête noire*—induction.

Referring to the above remarks about half-fledged electricians, these would hardly apply to the outside staff, as this is quite distinct from the indoor work, and is composed of engineers of standing, although the arrangements between the two are so complicated as to throw a good deal of the blame of the one on to the other.—Yours, &c.,

EXPERIENTIA DOCET.

London, May 7, 1884.

RAILWAY AND ELECTRIC APPLIANCES COMPANY (LIMITED).

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Every effort has been made to cause it to appear that I have endeavoured abusively and without reason to call in question the actions of some of the principal persons connected with the company, and furthermore that my object in doing so was entirely selfish and antagonistic to the interests of the shareholders.

In answer to all such attacks—and I submit that my object is to save my own property, which is represented by shares, and is therefore of exactly the same character as that of every other shareholder who occupies an independent position, and is not liable for irregularities personally or through his colleagues' insinuations—I will place at the disposal of the shareholders of the company, and invite their most thorough examination and criticism, the evidence which has forced me, in the protection of my own interests (which are solely represented by shares, and in common with other shareholders) to oppose the so-called "terms of compromise," which I do not hesitate (without fear of proof to the contrary) to condemn as exclusively individual interests and in every way prejudicial to the shareholders of the company.

Some of those who were mainly instrumental in promoting the company have introduced themselves into the management of the company's affairs, and the printing press has been freely used to make it appear that the terms of compromise are beneficial to the company.

Intermediaries came forward at the moment when the

Digitized by Google

directors, who had brought action against the promoters, found themselves saddled with the costs of the petition for liquidation.

These intermediaries are the intimate friends and colleagues of those who promoted the company, and if testimony sworn to by the friends of the Duke of Manchester and the London directors is of value, they are not only to be beneficially interested in the terms of compromise, but have much to fear if that compromise is rejected, and the just claims of the shareholders are enforced.

I submit that facts such as these constitute a grave *primâ facie* case against the disinterestedness of those by whom this proposed compromise has been arranged, and when it is remembered that at the recent meeting *absolutely no attempt was made to disprove such facts by the offer of any counter evidence,* their importance may be fully estimated.

It is worthy of the shareholders' most serious consideration that not one of the statements made in the pamphlet and circulars with reference to the conduct of some of the directors, the promoters, and others associated with them in the company's affairs has been refuted, nor has there been any attempt made at an answer.

These gentlemen have contented themselves with vague and entirely unsupported denials of the accuracy of some of the statements, and instead of endeavouring to satisfy the shareholders, in whose names they are supposed to act, they have resorted to the feeble and miserable device of evading facts with personal abuse and insinuations without even having truth as a base.

The speeches of Colonel Jackson and Mr. W. A. Smith at the meeting on the 18th April were confined to characterising the circulars and pamphlets as "amusing documents" and "very abusive to a plausible but disingenuous criticism of the balance-sheet"—which, however, was denominated "a mass of absurdities"—and to an attack on my motive by means of the improper use of a private letter and by some false statements about my connection with the Williams Company. These things I shall deal with in their place, but before noticing what is personal I shall call attention to what concerns the shareholders, in order to expose Colonel Jackson's attempt to divert their attention by mere side issues from what is of vital importance.

The shareholders must not be cajoled by any of the inspired notices which have appeared in some newspapers into the belief that Colonel Jackson's policy has carried the day. On the contrary, two very important obstacles prevent this, viz., first, the required majority of votes was not obtained to sanction the alterations in the Articles of Association, without which the directors are powerless to carry through the terms of compromise; and second, at present an interim injunction exists in the Court of Chancery restraining them from using the assets of the company in the way proposed under the said "terms of compromise of litigation."

It is to be hoped that the shareholders will adopt vigorous measures to protect their rights and property, and it is in order to aid them in this direction that I again call their attention to the facts of the case as already laid before them in the circulars and pamphlet regarding—

1. The promotion of the company, with its attendant irregularities.

2. The existence and management of opposition companies by some of the directors and promoters of this company.

3. The character of the arrangement with the National Electric Company.

4. The questionable use of some of the shares of this company.

5. The position of Mr. W. A. Smith and others in connection with the affairs of the company.

6. The claims of the shareholders against those who have caused them loss.

7. The irregularity of the meeting in August, 1883, and the character of the committee since acting.

8. The beneficial effects of the proposed compromise to the promoters and their friends, and this regardless of the future of the company or the cost to the shareholders or their rights.

9. The disastrous loss of £55,000 which the shareholders must sustain if the terms of compromise proposed by the directors are recognised by the shareholders.

10. The value of the railway patents and other assets possessed by the company.

All the statements in the pamphlet and circulars bearing on these matters may be held as established facts, as they are unanswered. Col. Jackson's only argument in favour of the compromise was that it would reduce the nominal capital of the company, and would prevent the expenditure of money in litigation. I repeat that this argument is utterly fallacious, because it does not tell the whole truth, for he omits to mention that *along with the extinction of the capital in this way goes necessarily the extinction of the very assets which the company was formed to acquire and work.*

The statement about expenditure of money in litigation is no more trustworthy, because it conceals the fact that if it is the litigation against promoters and others which is meant, the shareholders are pretty certain to recover their costs and something more from it; while if it is the litigation with the dissentient shareholders which is alluded to, the surest way to lose costs, as well as the whole amount involved in these actions, is by adopting Col. Jackson's policy, which is solely beneficial to others than the general body of shareholders. I do not deny that it would be a good thing to reduce the share capital of the company by the extinction of £50,000 of fully paid shares, but I maintain that *this should be and can be done without parting with the property of the company.*

In this case there would be "assets" in existence which would be "freed from a very heavy charge" upon them, and there could be "profits" upon which a reduced capital would be "entitled to claim."

In any other view the arguments and policy advanced and advocated by Colonel Jackson are entirely delusive, and the fact that the compromise means plainly a direct loss to the shareholders of £55,000, besides the entire liberation of those who are at present claimed to be liable to the shareholders for loss and damage, is enough to prove that the scheme of compromise as advocated by Colonel Jackson is, from the shareholders' point of view, more than "a mass of absurdities." It is to be hoped that Colonel Jackson and his friends are not deceived into supposing that such an arrangement can be allowed.

As to my balance-sheet, which shows the results to the shareholders by rejecting the terms of compromise and realising the just claims of the shareholders, Colonel Jackson has announced that the Williams Company is without capital, and is in liquidation, and he unhesitatingly affirms that it would not only be "very difficult" to get £29,500 from a company in this position, but also that "it is important to know that £29,500 cannot be got out of the Williams Company. But does not Colonel Jackson himself propose to get £24,000 out of that company under the "terms of compromise of litigation?" How then does he expect to get this amount from a company which has no capital and is in liquidation? Are we to apply his own argument to himself, and assume that after all the terms of compromise "are only a sham?" The truth is that he knows well where the £24,000 of the £29,500 referred to in my statement is to come from, and as to the balance he knows also that the liquidator of the Williams Company retains in his own hands £5,000 more, which was received from the Railway and Electric and Appliance Company, particulars of which he did not expose at the meeting. It is therefore evident that the assets of the Williams Company are good for £29,500, the amount named in my balance-sheet as recoverable from it. Col. Jackson also stated that the National Company has only "£8,000 or £9,000 of capital left," or, in other words, that the capital of this company is only £1,000 or £2,000 more than the sum it received in cash from the Railway and Electric Appliances Company, and he calls upon me to "explain how £22,000 are to be got out of a company that has only £9,000."
I therefore submit Col. Jackson has omitted to notice that

Digitized by Google

under the "terms of compromise" he credits that company with assets sufficient to purchase £15,000 worth of property from the Appliances Company, and as he admits the existence of other £9,000, it is evident that in criticising adversely my balance-sheet Col. Jackson misrepresents the true state of that company's affairs.

Col. Jackson does not agree with me as to the possibility of recovering damages from the promoters and others. He could not be expected to accept my view readily under the circumstances, but I confidently submit, if the shareholders of the company will take in hand the management of their own affairs, the force of circumstances may be found sufficient to induce a material change of views in Col. Jackson, and probably in others also.

In presence of such facts as are at the command of the shareholders it is not difficult to enforce a recognition of their just claims, and prevent the loss of £55,000, which would be the result under the proposed terms of compromise.

This is a case not without precedent, as must be well known by some of the directors, and therefore the solemn warning of Col. Jackson about "ruinous costs" and "loss of assets" is the mere conjuring up of a spectre to terrify the shareholders. Why he should bring in "loss of assets" in *this* connection it is difficult to imagine, because that is exactly the result of the compromise which he so ardently advocates. Even failure in these actions will be no worse than the results from carrying out the terms of compromise.

Col. Jackson prophesied boastfully that failure would be the result of "the attempt" to set aside the terms of compromise, and he announced in the same spirit that the number of proxies held by the directors was sufficient to "outvote and checkmate the attempt to govern the affairs of the company" in a way which he considered as likely to be to its detriment. It is therefore fair to analyse the measures adopted to secure the fulfilment of Col. Jackson's predictions.

It appears from the poll that the total number of shares voted in support of the "terms of compromise" was 57,917, but of these 40,450 are the very shares which in their report the directors told the shareholders had been assigned to Col. Elliot and Col. Jackson in trust for the company. I submit that such shares held in trust for the benefit of the company should not be used against the shareholders of the company; but Col. Jackson did not hesitate to employ them, and solely by their use to secure his seat upon the Board and to prevent the removal of Mr. Smith, and to carry the terms of settlement with his friends which are disastrous to the shareholders, although Col. Jackson had previously denounced these shares as "an incubus" and as "that element which presses most against the interest" of the capital of the company. He did not scruple to urge that the possession of fully paid up shares and the voting of them by others was directly antagonistic to the interests of the shareholders, and yet he is found using shares obtained in the promotion of the company, and by such means only is it possible for him to swamp the shareholders holding ordinary shares who oppose his policy. He may urge that some ordinary shares are also found in the majority. That is true; but of these ordinary shares so voting 11,644 were held by the vendors and promoters, and those especially connected with them, while 3,700 more were held by the directors and their relations. If these numbers are added together and subtracted from the total number voted in favour of the compromise resolutions there will appear 2,123 as the number of presumably independent shares voted for these resolutions, but in this number is included probably the shares of Mr. Arrol, one of the directors.

This result shows conclusively that outside of those who were directly concerned from personal and pecuniary reasons the general body of shareholders gave no support to the policy which sacrifices both their property and their just rights.

Even if we allow that the number 2,123 given above is entirely made up of independent ordinary shares, the number of such shares voted against the resolutions is much in excess of those held by the directors.

The total of 25,216 voted against the resolutions contains my fully paid shares, and shareholders who could not be present trusted to the weight of these being used in their interests. All that Col. Jackson can urge or has urged against these shares being regarded as identified with the shareholders' interests is that they are fully paid, or, in other words, that I am not subject to calls which the directors cannot under these proceedings long avoid, and that I personally do not care for the shareholders' interests, but only to make money for myself at their cost. These statements or insinuations are characteristic of the tactics resorted to by Col. Jackson in his efforts to effect a compromise so beneficial to his allies and so disastrous to the shareholders, of which I am one.

The evidence given in my pamphlet of the value of the railway patents, some of which I in part conveyed and some of which I wholly conveyed to the Appliances Company, is incontestable, and it was endorsed, if that is of any importance, by Mr. Smith at the meeting on the 18th inst. I submit that I conveyed property of value to the company in exchange for shares, and unless these shares are made valuable by the proper administration of the company's affairs I shall have given my property and received worthless paper. I submit that I am exactly on the same level and in the same category as those who have given money for their share certificates.

But both Col. Jackson and Mr. W. A. Smith insinuate that I have already received £20,000 in cash and £20,000 in shares from the Williams Company for these same inventions (which shares I hold). This is untrue, and Mr. Smith adds that having obtained my money from that company I "left it in the lurch" (which is also untrue), thus insinuating that I caused it not to succeed. This insinuation has expanded possibly under influence or inspiration so as to appear in a paper as a bold declaration that I endeavoured "to wreck the company," and this paper is the one which has been selected by the directors as the vehicle between them and the shareholders; but the persons responsible for the libel will meet with punishment in the proper quarter.

The £17,500 of shares I received from the Appliances Company represents the shares and the interest I possessed in the Williams Company and the further railway patents conveyed by me direct to the Appliances Company, and I transferred to the Williams Company the £17,500 of shares I held in that company.

I submit in contradistinction to Mr. Smith's statement that I expended several thousand pounds in prosecuting and pushing the business of the Williams Company after its formation, supplied the company at my own cost for some years with almost every illustration of the appliances which it possessed, and with nearly every model, and lent the company considerable sums, from which I did not derive one penny of advantage, and ever since the Railway and Electric Appliances Company acquired these patents I have spent considerable sums in the preparation of plans and documents and in personal endeavours to carry through the contract with the Wemyss Bay Railway Company. These efforts would have been successful long ago had I not been persistently met and hindered by conduct of the most unsatisfactory character on the part of those managing the affairs of the company.

I have only yet to refer to the private letter to Mr. J. E. Watson, which Col. Jackson, without explanation or apology, read at the meeting in order to make it appear that my motives were antagonistic to the shareholders.

As to my object, it must be evident that if I did not hold shares in the company I would not have any interest or right to oppose, but believing as I do that the policy of the directors is bad, and that the terms of compromise are not only absurd but ruinous to the shareholders, I as a shareholder preferred to retire from the company in preference to remaining as a shareholder if the assets of the company are to be squandered as under the proposed terms of compromise.

But as I have unwillingly been forced to expend time and money to protect my shareholding, and have received the votes of others in opposing the ruinous policy of the directors, my position to-day is different from when I wrote the referred-to letter, and I am fully convinced that the directors have not the power to compromise the actions of the serious character which they themselves instituted.—Yours, &c.,

JOS. S. WILLIAMS.

London, May 9, 1884.

THE DIAMETER OF CONDUCTORS TO PREVENT OVERHEATING IN ELECTRIC CURRENTS.*

BY PROFESSOR GEORGE FORBES.

The heating of conductors by the passage of an electric current is injurious to the insulation if the conductor be insulated, and may lead to risks from fire.

In small installations the heating of conductors is always small, because of this fact—that if contractors were to lay down wires so thin that overheating ensued then we may be sure that the resistance would be far too great for the capabilities of the dynamo machine.

But in large installations, currents of much greater density being carried, the heating may be very great, although the resistance of the circuit is small; and it becomes a matter of the utmost importance to know how the heating depends upon the size of conductors and the current density.

I have searched in vain for experimental facts on a large scale, and in absence of these have undertaken the mathematical solution of the problem, and confirmed my results by a few experiments on small currents, besides such isolated examples of measurements of large currents as were available.

I have been at some trouble to determine carefully the nature of conductors which would be required to carry a current capable of supplying 100,000 lamps—say, 70,000 amperes. It may be said that no such conductor would be required—that electricity will be so carried in a network of conductors that in no part will the current carried be excessive. It may further be said that high tension currents will be used to charge accumulators in series, scattered here and there over a district, and that, consequently, small currents only will be required in the mains. To the latter objection I say, that to carry out some of the provisional orders granted by the Board of Trade, the system of secondary batteries being inadmissible, it will be necessary to carry through the mains current sufficient for all the lamps. To the former objection I say that the supply of gas gives us a valuable insight into the similar progress which must be made in the supply of electricity. The problems are remarkably similar, and a due attention to this fact will save the pioneers of electricity much useless expenditure of time, money, and thought. But in gas lighting we carry enormous mains for distances of many miles from the place of manufacture. Witness the huge 4ft. pipes laid through this district last year to carry gas from Wandsworth to the City. There is no network of conductors here; it is found necessary to carry in one main gas enough to supply hundreds of thousands of gas lamps. Let it be well noticed, also, that it would be possible to force the gas at high pressure through narrow tubes to fill and supply gasholders spread about in different parts of a district. The analogy to the proposed system of charging accumulators at high tension is perfect, and this leads me to doubt very much whether the system which has not been found advisable with gas is likely to be successful with electricity.

I still maintain that to supply the electric light on a large scale we must face the problem of finding out what conductor will carry a current of 70,000 amperes without overheating.

Now, in doing this we are going a step in advance of what has been done before, just as (to cite, as example, a contemporary engineering work), in designing the Forth Bridge, Messrs. Fowler and Baker are extending the principles of bridge-making to magnitudes hitherto unknown. Here the laws of the stability of bridges are known, and, with experience on smaller bridges, combined with laboratory tests of the strength of materials, a sure advance can be made to the larger structure. It has been my endeavour to find out whether, with the facts at our disposal as to the smaller currents carried by smaller conductors, and the laboratory experiments on the nature of our conductors and insulators, we are in a position to propound laws which shall be a guide to us in extending these principles to the construction of a suitable conductor for very large currents, say of 70,000 amperes.

* Paper read before the Society of Telegraph Engineers and Electricians.

In 1882 the Fire Risks Committee of this society discussed the question, and I believe I am right when I state that it was seriously proposed as a rule, to prevent overheating of the wires, that the permissible current should be so many amperes per square inch section. I have often heard this error repeated. I believe it has actually been adopted by the fire insurance companies as a measure of safety, and a precise 1,000 amperes per square inch has been given as the safe current. With regard to the insurance companies, little harm has been done by this, because they have had only small installations to deal with at present, and, as above stated, there is practically no danger from this cause; but it seems surprising that in one breath they should tell contractors that in small installations they must not raise the temperature of their conductors $\frac{1}{10}$ of a degree, and that in large installations they may make their conductors red-hot.

As a matter of fact, in any installations, except very large ones, the safe conductor ensures greater economy than the unsafe one; and Sir William Thomson has done well* in fixing the size of conductors by commercial considerations when he showed that the interest and depreciation on the cost of conductors should equal the annual loss of horse-power in heating up these conductors.

There is a limit above which this rule does not apply, because the heating becomes so great that the insulation is injured. The first person who, so far as I know, has taken notice of this is Mr. Cowling Welsch, in a table published by Messrs. E. and F. Spon. He fixes the limit at 2,700 amperes, but he does not state what he considers to be the limiting temperature which is tolerable, nor does he specify the nature of the insulation. His facts seem to be taken from the tests of Messrs. Clark, Forde, and Taylor (see below). Mr. A. Gray has also taken notice of the failure of Sir William Thomson's law for high currents, in a paper contributed to the *Philosophical Magazine* in 1883, and fixes the limiting value at 5,000 amperes.

I shall not take up the question of how Sir Wm. Thomson's rule is to be applied commercially. I have resolved in this communication to confine myself to one point—the strength of current which can be carried through a wire under different conditions without overheating.

I find that two writers have worked at this subject from a mathematical point of view, and each has worked out some concrete examples. One of these is Mr. Day, of King's College, whose useful little book, "Electric Light Arithmetic," should be studied by all learners. The other author is Mr. A. Gray, formerly a pupil of my own, now Sir William Thomson's assistant. His remarks on the subject appear in the *Philosophical Magazine*, September, 1883. In discussing the question of bare wires both of these authors assume that the cooling effect is proportional to the surface, and they make no reference to the variation from this law which I pointed out in 1882 to the British Association, and which has been confirmed by Mr. Preece. Mr. Day deals only with the case of naked wire, in which he arrives at the theoretical law—(currrent)^2 $\propto$ (diameter)^3—which I published in 1882, but which I also showed at that time to be contradicted by experiments on a small scale. My own view of the matter is, that while of course radiation is proportional to surface, convection is not so, but is nearly constant for rectilinear wires of different diameters but the same temperatures, and that with thin wires consequently convection is the most important factor, but for thick wires radiation proportional to surface is the ruling factor; hence the tables which I have computed are correct for large diameters, but with small wires greater currents may be safely carried.

Mr. Gray has also gone partially into the theory of an insulated cable, and arrived at formulæ very similar to my own.

Some experiments were made by Messrs. Clark, Forde, and Taylor for the Indian and Oriental Electrical Storage and Works Company in the last year or two, and the results are published in *The Electrician* for April, 1883. The general conclusion arrived at is, that up to 10 amperes it is safe to allow 1 ampere per 10 pounds of copper per mile, either with naked

* B. A. *Reports*, 1881.

wire or with insulated wires buried in sand, in the hot Indian climate. They furnish the following table :—

CLARK, FORDE, and TAYLOR'S TABLE.

B.W.G.	Diam. Mills.	Weight in lbs. per mile.	Amperes.	Lbs. per ampere.
22	28	12·4	2·33	5·32
21	32	16·2	2·84	5·70
20	35	19·5	3·27	6·20
19	42	28·0	4·3	6·5
18	49	38·1	5·4	7·0
17	58	53·3	6·9	7·7
16	65	67·1	8·3	8·1
15	72	82·5	9·6	8·6
14	83	109·5	11·9	9·1
13	95	143·0	14·56	10·0

No information is given as to the temperature which is considered permissible.

In the second supplement of *The Electrician*, published in March, 1883, a table was printed, supposed to give the currents which could be safely worked through different thicknesses of conductor. This table, however, was founded upon the assumption that the safe-working current was proportional to the sectional area, which is now well known to be far from the case. I quote this simply as one example, out of many which have come to my notice, of the same mistake being made by people who ought to be better informed. Mr. Jamieson has given a similar rule of 1,000 amperes per square inch for small installations, with an insulation resistance for the whole circuit of not less than 1,000 ohms per volt of E.M.F. generated by the dynamo. As I have said, the question of safety does not arise in choosing the diameter of wire for a small installation.

There are five primary cases of conductors which must be treated separately—(1) Overhead naked wires; (2) Overhead cables; (3) Subaqueous cables ; (4) Subterranean and embedded cables; (5) Coils.

I have added the fifth case, of coils, because it is important in the manufacture of dynamos and magnets.

Each of these classes has its own peculiarities. In all of them heat is generated by the current, and this heat must be got rid of. In case (1) it is got rid of solely by radiation and convection; in the others partly by conduction, and in case (4) very largely by absorption. In case (1) the maximum temperature is reached almost immediately; in some of the other cases it may be many hours before the final steady flow of heat sets in.

Having convinced myself that the most satisfactory mode of attacking the problem was to treat it in a strict mathematical way, and being well aware that all the requisite data had been obtained by previous experimenters, I determined to work out practicable tables for the use of electricians from these data, including both bare and insulated conductors. The first step was to solve the following problem :—

PROBLEM I.—*To find the law connecting diameter*, D, *of conductor with that strength of current*, C, *which raises its temperature by a fixed amount t° cent. above that of the surrounding air.*

Let R = the resistance in ohms of a cubic centimetre of the substance of the conductor (= its specific resistance).

Let E = the heat radiated per second from a square centimetre surface when the temperature of the surface is 1° cent. above that of the surrounding air.

The radiation from the surface of 1 cm. length of the wire is $\pi D t E$, and this must equal the heat generated in 1 cm. length of the substance $= C^2 \cdot \dfrac{R}{\pi \left(\dfrac{D}{2}\right)^2} \times$ (number of units of heat in 1 watt) $= C^2 \cdot \dfrac{4R}{\pi D^2} \times \cdot 24$.*

Whence
$$\pi D t E = C^2 \frac{4R \times \cdot 24}{\pi D^2},$$

and
$$C^2 = D^3 t \cdot \frac{\pi^2 E}{R \times 4 \times \cdot 24} \quad \ldots \ldots \quad (a)$$

This shows that if the heat be lost by radiation, or by any means which is proportional to the surface, then, in order to keep all the wires of different diameters at the same temperature, we must have the cubes of these diameters proportional to the squares of the currents if the change of resistance with temperature be neglected.

Example :—To take, as a special example, the case of copper, we know that

$$R = \cdot 000001642 \text{ ohm}\dagger \text{ at } 0° \text{ centigrade,}$$

* Everett's "Units and Physical Constants." Joule's equivalent of a Gramme centigrade heat unit = $4 \cdot 2 \times 10^7$ ergs, and one watt = 10^7 ergs, ∴ ·24 = number of heat units in one watt.

† Maxwell's "Electricity and Magnetism," Vol. I., last chapter.

Digitized by Google

and increases ·38 per cent. per degree centigrade;

$$E = \cdot 000168 \text{ (polished), or } \cdot 000300 \text{ (blackened).*}$$

To take an example, let $C = 10$ amperes; let the wire be No. 16 B.W.G. $= 0{\cdot}165$ cm.; the rise of temperature comes out $t = 21{\cdot}2°$ C., polished, or $t = 15{\cdot}0°$ C., blackened.

This table is calculated from the formula

$$C^2 = D^3\, t \cdot \frac{\pi^2 E}{4\,R \times 0{\cdot}24}$$

C = current (amperes).
D = diameter of wire (centimetres).
t = excess of temperature (centigrade) above air.
E = coefficient of radiation and convection.
R = specific electrical resistance (ohms).
$\cdot 24$ = number of gramme-centigrade heat units in a watt.

Temperature of the air assumed 20° C.

$$R = 0{\cdot}000001642\left(1 + \frac{\cdot 38t}{100}\right).$$

$E = \cdot 000168$ for polished, $\cdot 00032$ for bright, copper.

The accompanying Table I. has been computed from the formula obtained above. It gives the rise in temperature in bare copper wires with different currents.

(TO BE CONTINUED.)

* This is taken from D. M'Farlane's experiments (*Proceedings* Royal Society, Edinburgh, 1872, p. 93), in which radiation took place from balls of considerable size, and consequently convection played an unimportant part. If the rise in temperature were 100° or more, it would become necessary to take account of M'Farlane's second and even third terms, depending on t^2 and t^3.

LITERATURE.

A History of Electric Telegraphy to the Year 1837, *chiefly Compiled from Original Sources and hitherto unpublished Documents.* By J. J. FAHIE. Illustrated. [E. and F. N. Spon. 1884.]

We enter upon the notice of this work with feelings of a very mixed character. Mr. Fahie, in his preface, calls attention to our share in the matter of assisting him to put his work before the world. That our correspondence with Mr. Fahie in far-off Persia did not end so satisfactorily as a personal interview is hardly a matter for wonder. In the one case he described his work; in the other he placed the MSS. before our eyes. Our readers will no doubt agree that such an interesting history ought not to be lost. It cannot now suffer the fate of the history of the old castles referred to in the preface. We, perhaps more than others, know the difficulties under which Mr. Fahie has worked. In Persia, as he says, books are at a discount. There he had few facilities for research, and it is a wonder that, even with his inexhaustible energy, such a mass of material could have been collected. After fifteen years' absence he came home, ostensibly for a holiday, and spent that holiday in continuous work. He ransacked libraries, paid visits to those whom he thought might give information, and wrote letters all round in order to obtain the fullest and most accurate details of all that pertained to the history of telegraphy. It goes almost without saying that his whole heart was in the work. This cannot be shown better than in the manner in which he obtained the details of Davy's work after once the clue was in hands. Then his great desire was to see Davy's claims publicly recognised. He thought, and justly so, that Davy's work should stand at least upon as high a pedestal as that of Cooke and Wheatstone. There is no doubt the supineness of the Society of Telegraph Engineers was a great blow to Mr. Fahie. He hoped to see the society representing telegraphy and telegraphists enter with some of his own enthusiasm into the question of Davy's position in the annals of telegraphic enterprise.

The work of Mr. Fahie would be extremely valuable, even if it contained nothing else, for the exposition of Davy's claims. We agree with Mr. Fahie that if honour is due to Davy it should be given now while he is living. What is the use of the tardy acknowledgment of a man's claims if he is dead? We are, however, diverging from our immediate object, viz., the bringing of this book to the notice of our readers. It is one well suited to every library, filling a void in telegraphic literature, altogether of a non-technical character, and as interesting to the non-mathematician as to the mathematician. The general idea of "electrical" books is that they are books through which a host of more or less unintelligible formulæ are scattered. Here is one, however, purely historical—one that can be appreciated by all readers. The information it contains has been collected with much labour, and verified with great care, and is such as should appeal to every member of the profession. We ought to be very jealous to see due credit given to every pioneer in the great work of introducing telegraphy, and if we err at all it should be on the side of being too generous.

Mr. Fahie, in the first place, shows the foreshadowing of the electric telegraph, then deals with static electricity and the telegraphs based upon static electricity, this being followed by a similar disquisition in dynamic electricity and apparatus based thereon. Electro-magnetism and electro-magnetic instruments then claim attention, bringing us to the work of Davy. The index to the work has been prepared by Mr. A. J. Frost. We have done but scant justice to this book, both book and author deserving all the praise we can give them.

A Concise Treatise on the Law and Practice of Patents for Inventions, consisting of the Patents, Designs, and Trade Marks Act, 1883. The New Rules and Numerous Notes and Cases by CLEMENT HIGGINS, Barrister-at-Law. [William Clowes and Sons. 1884.]

Handbook to the Patents, Designs, and Trade Marks Act, 1883. Containing the Act and Rules. Also an explanatory and Practical Treatise thereon, and the Procedure thereunder, for the use of Inventors, Manufacturers, &c. G. BRISTOW HUNT. [Waterlow and Sons. 1884.]

These works differ from each other, and from that of Messrs. Clark referred to in a previous notice, though treating of patents, &c. The former of the two now mentioned is written more from the legal standpoint; the latter is both legal and practical. Both have their good points and their particular uses. The one will most probably be referred to when the question to be decided is a legal one; the other is more for general reference. Mr. Higgins gives a fairly complete table of cases and a good index, valuable parts of such works as this. In fact, all the books are good in respect to indexing.

A Bibliography of Electricity and Magnetism, 1860 to 1883, with special reference to Electro-Technics. Compiled by G. MAY, with an Index by O. SALLE, Ph. D. [London: Trübner and Co. Vienna: Hartleben. 1884.]

This book partakes of the nature of a bookseller's catalogue of the books and pamphlets on electrical subjects issued between 1860 and 1883. It shows that the literature of the subject is enormous, and the wonder is when the supply will diminish.

MAGNETISM AND ELECTRICITY.

BY CHARLES F. CHANDLER, PH.D., PROFESSOR OF CHEMISTRY AND MEDICAL JURISPRUDENCE.

[We reproduce the following lecture in answer to a frequently-repeated demand for elementary information, in a condensed and popular form, such as might be available to those who, without having the time or the desire for scientific study, are inclined to take a practical interest in some of the applications of electricity. The American professor has certainly succeeded in compressing within narrow limits a considerable amount of knowledge, which, being expressed in familiar language, may be acceptable to the class to which we have referred. At the same time, although allowance should be made for the conciseness aimed at and realised by the writer, there are some statements in his paper which are open to objection, and which we may leave for the present to the

Digitized by Google

criticism of students who in this country have had impressed upon them views adverse to the statements in question.]

Magnetism.

I will say only a word about magnetism. A magnet is either natural or artificial. A natural magnet is a piece of magnetic iron ore or magnetic oxide of iron (Fe_3O_4), also called loadstone, and it occurs in nature. An artificial magnet is one produced by artificial means. Artificial magnets are of two kinds—permanent and temporary. A permanent magnet is a piece of steel that has been magnetised by bringing it in contact with another magnet or piece of loadstone, or by passing a strong current of electricity around it. A temporary magnet is a piece of soft iron which has been made temporarily magnetic by being brought near to a permanent magnet, or by passing a current of electricity through a coil of wire surrounding it. The properties of a magnet are :—1. The power of attracting certain metals—iron, nickel, cobalt, and, to a slight degree, chromium, and a few others. 2. The property of tending to assume a certain position as regards north and south. A magnetic bar or needle, if allowed to hang by its centre on a string, or to float free on a piece of wood in water, will assume a position approximating north and south, but not exactly so. 3. The property of polarity—that is to say, a magnet—exhibits its peculiar attracting powers chiefly at the extremities. There is a centre of attracting power near each end, but not absolutely at the end, and at this point or centre the magnetic power is strongest. These two magnetic centres are called the poles of the magnet ; the end which points toward the north is called the north pole, and the one pointing toward the south the south pole of the magnet. When two magnets are brought near each other, the north pole of one will attract the south pole of the other, and repel the north pole. So it has been found to be a law with magnets that "like poles repel, and unlike poles attract each other."

With regard to the direction the magnetic needle takes when allowed to move freely, it does not point directly north and south, but it assumes a position pointing a little to the east or to the west of north and south, depending upon the locality at which the observation is made. This is because the magnetic poles in different parts of the earth do not correspond exactly with the geographical poles, and the difference between them varies with the location at which the observation is made. This is why nautical almanacs are made to tell mariners the amount of variation from the true north and south made by the compass-needle in different parts of the world. This deviation of the compass-needle from the true north and south is called the "declination" of the needle. The term "declination" is very liable to be confounded with that of "inclination." When a bar of steel is hung by a thread at its centre, it assumes an exactly horizontal position ; but if this bar of steel is now magnetised, it will assume a direction pointing north and south, but it will no longer hang exactly horizontal except at the equator of the earth.

At all points north of the equator the north pole of the bar will dip downward, and the farther north you get the greater will be the dip, while at all points south of the equator the south pole of the bar will dip downward ; and the degree to which the needle dips from the absolutely horizontal direction is called its "inclination." This is because the two magnetic poles of the earth do not correspond to the two geographical poles, but they appear to lie nearer the centre of the earth. To overcome this tendency of the magnetic needle to dip at a varying angle according to the distance north or south of the equator, the needle of the mariner's compass is made by uniting two magnetic bars laid parallel, with the north pole of one adjacent to the south pole of the other, so that they lie with their opposite poles end to end. Such a needle is said to be "static." At a point on the surface of the earth corresponding with latitude 70° N. and longitude 96° 43′ W. the north magnetic pole seems to be located, and at this place the dipping needle assumes a vertical direction. The south magnetic pole is apparently located at latitude 75° 5′ S. and longitude 154° E.

The production of magnetism by induction is a curious phenomenon. If a permanent magnet is brought near a handful of iron nails it will attract them to it, and as soon as a nail becomes attached to the magnet it becomes a magnet itself and attracts another nail, which in turn becomes a magnet and attracts another, and so on, the magnetic power of each new nail attracted becoming constantly less than that of the preceding one. It is not even necessary that the nail should absolutely touch the magnet in order to assume this magnetic power, for it will be transmitted through short spaces from one to the other. This power which a body acquires by being brought near a magnet is called "magnetic induction." An important fact in this connection is that when a coil of iron wire is made to surround a permanent magnet it becomes magnetic itself by induction, and is capable of inducing magnetism in another bar of iron surrounded by it. This principle is made practical use of in the construction of the telephone and magnetic telegraph.

Electricity.

We now come to the subject of electricity. This is a peculiar agent, capable of producing certain astonishing results. There are different forms of electricity and different ways of generating it. The different forms are statical electricity, dynamical electricity, and magnetical electricity, or magnetism. It may be generated by means of friction, percussion, heat, chemical action, cleavage, and by magnets. The effects of electricity in its different forms are manifested as attraction, repulsion, light, heat, violent commotions, and chemical decomposition.

To excite electricity we must always do something, and the first way of producing it, discovered in the earlier ages, was by rubbing amber, and so the term electricity was derived from the Greek word ἤλεκτρον, signifying amber. It was afterward found that certain other substances when rubbed assumed electrical properties, and would attract or repel other materials. This electricity produced by rubbing or friction is called statical electricity. This is a form of electricity that can be held for a considerable length of time, and hence it has received the name of stationary or statical electricity. This is the only form of electricity that we can store up and keep for a time. What is known now as the storage battery does not really store up electricity, but only energy, which can be transformed into electricity at will. So much for statical electricity.

We have a totally different kind of electricity, called dynamical electricity, or electricity in motion. This is a form of electricity that circulates only in a conductor or along a wire, and it cannot be held. It was first discovered by Galvani in experimenting on frogs' legs, and hence it is often called galvanic electricity. It is now ordinarily produced by means of galvanic batteries and dynamo machines. The third form of electricity we have already referred to incidentally as that which is induced by means of magnets, and it is therefore called magnetic electricity, or magnetism.

According to the generally accepted theory there are two so-called electrical fluids, and these two are commingled in equal proportions in all bodies; and hence all the processes for getting electricity must result in pulling these two electrical fluids apart, and in taking a portion of one away from a body. These two fluids are called one positive and the other negative electricity. It is found that when two bodies are electrified with the same kind of electricity, as both with positive or both with negative, they repel each other ; but when the two bodies are charged with opposite kinds of electricity, as one with positive and the other with negative, or when one body is charged with either kind while the other is left in its normal condition, then the two bodies attract each other. Hence we derive the law which states that "bodies charged with like forms of electricity repel, and those with unlike attract." The gold-leaf and pith-ball electroscopes are constructed on this principle.

When a piece of sealing wax is rubbed it manifests electrical properties for some time, but certain other substances, like metals, for instance, after being rubbed in the same manner, show no electrical properties, and this is because the electricity easily gets away from them. Thus we find that while certain substances remain electrified for some time others

Digitized by Google

do not, and hence these bodies are named conductors and non-conductors. But these terms are not absolute, but only comparative. The metals, carbon, gypsum, and acids are called good conductors, while amber, glass, sulphur, and silk are poor conductors. If we want to insulate electricity, and keep it from running off into surrounding objects, we surround the object containing it with a poor conductor. Thus, the glass insulators on telegraph poles prevent the electricity from leaving the wires and running off into the ground, and the non-conducting materials placed around the wires of the Atlantic cable so protect it that a small charge of electricity will carry a message from here to Europe.

Great difficulty is experienced in experimenting with statical electricity, because it so easily gets away. All substances are conductors to a greater or less degree, including the dust in the air and the moisture in the atmosphere. Perfect insulation and a warm, dry air are therefore favourable conditions for holding statical electricity. The reason it was not used earlier for practical purposes was because it was so difficult to manage. The electricity which is produced on glass by friction is called vitreous or positive, while that produced in the same manner on shellac or sealing wax is called resinous or negative electricity.

Franklin had a theory that there was but one electrical fluid, and that all substances in the natural state had an equal amount of it, but a body charged with an excess of this fluid was said to be in a positive state, and one in which there was a deficiency was said to be in the negative state.

But this theory has now given place to the two-fluid one, which maintains that all bodies are charged with an equal amount of the two electrical fluids called positive and negative, but when a body is electrified these two fluids are separated so that one remains in excess of the other. There is always a passage of the electrical fluid in two directions along a conductor, but, when the direction of the current is spoken of, it is the direction of the positive current that is always meant. Statical electricity can also be produced by pressure, as when certain crystals are firmly pressed together; by cleavage, as when two layers of mica are split apart; and by heat as well as by friction. It may also be produced by torsion. It is found that the charge of electricity, if collected in a spherical body, is on the outside, and not within the body; and if it is not a spherical body, the electricity collects chiefly at the part most nearly pointed. This kind of electricity is transferred in three different ways:—1. By conduction from one body to another in contact with it; 2, by convection, where gas or the air in contact with an electrical body takes away some of its electricity; 3, by discharge, where a highly electrified body suddenly loses a portion of its charge.

Electrical Machines.

Machines for producing statical electricity are usually based on the friction method. The old-fashioned machine consisted of a circular glass plate which was rotated between two cushions, and the electricity thus produced was taken off and carried to a metallic cylinder, called the prime conductor, by means of metal points. Silk and glass as insulators prevented the electricity from running off into neighbouring objects. More recently machines have been constructed on the principle of induction, as illustrated in the electrophorus. These are known as the Holtz machines.

The condensation of electricity is illustrated in the Leyden jar. This is a sort of bottle, lined up to a short distance from its top, both inside and outside, by tin foil, and in the stopper is a brass knob which is connected with the tin foil on the inside of the jar by a chain. When the knob is charged with positive electricity from a machine, it collects on the tin foil inside the jar, while a corresponding amount of negative electricity collects on the outside of the jar. By this means a large amount of electricity may be collected and held by the jar until discharged, by making connection between the tin foil on the inside and that on the outside of the jar. The electricity is held, not on the tin foil, but on the surface of the glass. This is proved by means of a jar that can be taken to pieces after being charged—although the two pieces of metal which lined the inside and outside are now brought into contact, yet when the whole is put together again the charge is found to remain, and it is discharged by connecting the knob with the metal lining of the outside. All that these metal linings accomplish here is to make a large conducting surface over the whole of the glass upon which the electricity collects.

The discharge of electricity from such a jar, or a battery of several of them connected, produces a variety of results. The spark will pass through a thin plate of glass or a card and make a hole in them by disrupting them; or, in passing through points of metal, it heats them to a high temperature and vaporises them, so that we get luminous effects from them. Electricity is estimated to travel at the rate of two hundred and eighty-eight thousand miles in a second.

Franklin first showed that lightning was simply a discharge of electricity from the clouds to the earth, and it occurred to him that, as points condense electricity and draw it away and discharge it quietly, lightning rods might be made on this principle that would prevent the disruptive effects of a discharge of lightning, and so be a protection to buildings on which they are placed. Such lightning rods are really a protection when properly made. A perfect one should be large enough to carry the charge of electricity, should have no break in it, should terminate at the top by numerous points, and connect at the bottom with the ground below the water line, and there be surrounded by fragments of iron buried in moist earth. It is well also to have it connected with the metallic water and gas pipes running through the house.

Dynamical Electricity.

Now, a few words in regard to dynamical electricity. Galvani discovered, in experimenting on frogs, that when two pieces of metal, like copper and zinc, were placed in contact with the frog's leg and their ends connected, a movement of the leg would take place. This discovery gave rise to considerable discussion and experimentation, and, as a result, Volta developed the voltaic pile, which at first consisted of alternate layers of zinc, wet paper, and copper, piled one on top of the other in varying numbers. It was found that when the top layer was connected with the bottom one by means of wires a current of electricity was set up. It became understood then that the electricity was produced by the chemical action of the water in the paper on the zinc, and so more active solvent fluids came to be used instead of water, and cloth was substituted for the paper. It was found that the zinc was the positive element here and the copper the negative, and it is usual to find in all batteries that the metal acted upon is positive, and the one not acted upon is negative. There is now, practically, only one metal used for the positive element, and that is zinc, for it is the cheapest and the best.

The Galvanic Battery.

A galvanic battery is simply a combination by which we produce this chemical action, and zinc is the metal acted upon. The principle of the galvanic battery is this: If we immerse two pieces of metal, like copper and zinc, in a liquid like sulphuric acid contained in a glass vessel, and then connect the two metals by pieces of wire, a current of electricity is set up, because the liquid is decomposed by the zinc, and the H_2SO_4 is split up into SO_4 and H_2, and the H_2 is set free while the SO_4 unites with the zinc and forms Zn_2SO_4. The H set free tends to collect upon the surface of the negative element, and in this way the copper finally becomes "polarised" by the hydrogen. The positive element, the zinc, always drives the positive electricity through the fluid toward the negative element, the copper. The wires which conduct the currents from one element to the other are called electrodes, and the one coming from the zinc is the negative electrode, and the one from the copper is the positive electrode. While zinc is universally used for one element, the second element in the battery may be composed of different kinds of metals, according to convenience.

A difficulty in using zinc as the positive element was soon found in the fact that little local currents were set up between it and the impurities contained in it, and this caused an unnecessary waste of the zinc. So it became customary to amalgamate the zinc in order to prevent this local action of the fluid

Digitized by Google

upon it. The next improvement made was to prevent the little bubbles of hydrogen from collecting on the surface of the copper, thus keeping the liquid from coming in contact with it in all parts—that is, to prevent the "polarisation" of the copper. For this purpose certain substances came to be used to absorb the hydrogen. The first of these substances was the sulphate of copper as used in the Daniell battery. This consisted of a copper vessel containing a porous cylinder in which was suspended a rod of zinc. Dilute sulphuric acid was contained in this cylinder, and in the copper vessel outside of the cylinder was placed a solution of the sulphate of copper. In this battery the hydrogen set free decomposes the sulphate of copper, forming with it sulphuric acid, and sets free copper which collects on the copper element.

Grove's battery consists of a glass vessel containing a porous cup surrounded on the outside of a coil by amalgamated zinc, and on the inside is suspended a rod of platinum instead of copper. The vessel outside of the porous cup is filled with dilute sulphuric acid, and inside with strong nitric acid. The nitric acid absorbs the hydrogen set free by the sulphuric acid and zinc. In the bichromate battery the bichromate of potash dissolved in sulphuric acid is used to absorb the hydrogen, and chromic acid is formed. So the three substances in use for absorbing the hydrogen in different kinds of batteries are sulphate of copper, nitric acid, and bichromate of potash. Bunsen suggested the use of gas carbon to take the place of the copper, or the negative element, because of its cheapness. So the Bunsen battery consists of a cylinder of carbon immersed in a vessel containing nitric acid, and within this cylinder is a porous cell containing sulphuric acid, in which a rod of zinc is suspended. To avoid using the porous cups, the force of gravity has been brought into play in the construction of the so-called "gravity battery." This consists of a glass vessel with plates of copper at its bottom, and upon this crystals of sulphate of copper are scattered, while over all is poured pure water, in the upper portion of which is suspended a plate of zinc. A very little sulphuric acid is added to start the battery, and then its action will keep up. Gravity here keeps the two liquids apart—the solution of sulphate of copper at the bottom, and the dilute solution of sulphuric acid at the top. This battery produces a constant current, and will run for a very long time. The Leclanché battery consists of a porous cup containing sal ammoniac in which is suspended a rod of zinc, and this cup is surrounded by the oxide of manganese as a depolariser, immersed in which is the carbon. This battery is used when a current of electricity is desired for a very short time at once, as in striking burglar alarms, signal bells, &c. In the dipping battery a plate of zinc is suspended between two plates of carbon, and, when in use, these are let down into a solution of bichromate of potash dissolved in an excess of sulphuric acid. This fluid is called the electro-poion. The galvanic battery is now being replaced for many purposes by dynamo-electric machines.

The Electric Light.

If a strong current of electricity is sent along a good conductor, it passes very easily; but, if passed along a poor conductor, it makes it hot. This is the principle upon which is based the incandescent electric light. A current sent over a fine thread of carbon heats it to a white heat, and thus produces a brilliant light. The same principle holds in the arc light, where the air acts as the poor conductor. Here two pointed sticks of carbon are placed in contact until a current is started through them, and then they are gradually separated for a short distance, when the resistance offered by the air to the passage of the electricity from one point to the other heats them to incandescence, and small particles of carbon in a state of combustion are broken off and carried through the air, thus causing an arc of light between the carbon points. The incandescent electric light and the arc light form two systems of electric lighting.

A current of electricity passed through certain substances will decompose them, and this process is called electrolysis. If it is desired to plate any object with a metal, that metal should be hung upon the positive pole of a battery, and the object upon the negative pole, and then, when an electrical current is passed through them, the metal on the positive pole will be decomposed, and a layer of it will be deposited over the surface of the object hanging on the negative pole. This process is known as galvanoplasty.

The most convenient method of measuring a current of electricity is by means of a rotating needle, around which the current is passed; and this is called a galvanometer.

The Electric Telegraph.

The electric telegraph is based upon the production of temporary magnets by passing a current of electricity through a coil of wire surrounding a bar of soft iron. All systems of electro-telegraphing involve a battery, a wire, a piece of soft iron surrounded by a coil of wire, a key or current breaker, and a sounder or indicator. Morse devised an alphabet, the letters of which were made up by various combinations of dots and dashes, which were scratched upon a strip of paper by the indicator. But telegraph operators soon found that they did not need to see these letters on the paper, for the ear quickly became educated to detect the letters by sound alone; so the paper was discarded, and now they hear, instead of see, the dots and dashes.

The Telephone.

It is found that, if by any means you change the strength of the magnetism in a permanent magnet, you will at the same time change the strength of a current of electricity passing through a coil of wire surrounding the magnet, and it is upon this principle that all the modern telephones are constructed. If in front of such a magnet a thin sheet of iron is fastened, and if the plate of iron is then approached a little nearer to the end of the magnet, the magnetic centre is brought a little nearer to the extremity of the magnet, and hence the magnetic power at this point is increased; at the same time a similar increase is induced in the current of electricity passing through the coil of wire surrounding the extremity of this magnet; and now, if in the same circuit of wire there is a second similarly arranged apparatus, the increased strength of the current passing through the coil surrounding the second magnet will induce an increase in its magnetic power, and hence the second plate of iron will be attracted closer to the end of the magnet. In the same way a slight withdrawal of the first plate from the end of the first magnet would cause a weakening of the magnetism in the second, and cause its iron plate to spring backward again. So, in speaking in front of the first plate, at every vibration of the air produced by the voice the plate vibrates in harmony, and a precisely identical sort of vibration is produced in the plate of the apparatus at the other end of the wire, and these vibrations can be heard as the sound of a voice. This is all there is to the Bell telephone, and it is the principle on which all telephones are constructed.—*N. Y. Medical Journal.*

THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

At the meeting of this society on Thursday, 8th inst., Professor Adams in the chair, a paper communicated by Mr. Henry C. Mance, member, was read by Mr. Latimer Clark, who introduced it with some explanatory remarks of his own. Mr. Mance's paper described a method patented by him and practised on the Persian Gulf cables during the past four years, and by means of which he had been able to eliminate the effects of earth currents and polarisation when testing for a submarine cable fault. There existed in the recognised text books plenty of formulæ on this subject, but in practice they were of little service on board ship. His method was of great use wherever the loop test was not available, and it furnished a permanent and reliable test as a basis of calculation, doing away with all uncertainty as regards earth current and polarisation. Two observations were required rapidly succeeding each other, so that no change of condition could take place at the fault in the interval. An ordinary Wheatstone bridge was employed, with proportional coils which could be instantly changed by an

Digitized by Google

apparatus of Mr. Mance's devising. Having two pairs of proportional coils of different values, say 100 and 1,000, the process was to make the test with one pair, and when steadiness was obtained to short-circuit the bridge for an instant, and then introduce the other pair. The formula for this method was as follows:—

Reading obtained with $\frac{100}{100}$ coils $= R^1$

Ditto with $\frac{1000}{1000}$ coils $= R^2$

Resistance of one of the proportional coils (100) $= P^1$

Ditto larger ,, ,, (1000) $= P^2$

Internal resistance of battery $= r$

Resistance of cable and of fault $= x$

Then
$$x = \frac{\overset{(A.)}{R^1(2r+P^2)} - \overset{(B.)}{R^2(2r+P^1)}}{R^2+P^2-P^1-R^1},$$

or
$$\frac{A-B}{\underset{(C.)}{C}} = x.$$

As an example of this working take the following:—

Battery (30 cells, negative) Resistance $= 4{\cdot}20$ ohms $= r$

$(P^1)\ \frac{100}{100}$ coils balance with 35 ohms $= r^1$

$(P^2)\ \frac{1000}{1000}$ coils ,, ,, 60 ohms $= r^2$

$$x = \frac{35 \times 1840 - 60 \times 940}{60 + 1000 - 100 - 25} = 8{\cdot}6 \text{ ohms.}$$

A large number of examples of how this method had served to correct the ordinary tests, and enabled Mr. Mance to localise cable faults with great certainty and celerity were furnished in the paper. Reverse currents not being used, and the tests following each other in quick succession, they are practically one. Mr. Latimer Clark added that Mr. Mance's method still left undetermined the resistance of the fault itself. As this resistance apparently increased with the distance between the fault and the observer, and with the strength of the battery, he suggested that it might be well to employ smaller proportional coils in these tests. He also drew attention to results obtained by himself so long ago as prior to 1862, and to tables published in *The Electrician* that year, the figures of which seemed to point to the possibility of formulating a law for determining the resistance of the fault itself. Mr. Mance's method had in practice no doubt been used before; but the merit of his present communication was the formula given above, which would be found very convenient for use in cable laying and cable repairing operations. Messrs. Latimer Clark, Muirhead, and Co., are the sole makers of Mr. Mance's testing apparatus.

A brief discussion ensued, followed by the usual vote of thanks.

LEGAL.

Wandsworth Board of Works v. United Telephone Company.

The plaintiffs claimed an injunction to restrain the defendants from retaining or placing telegraph or telephone wires across the streets in Putney, on the ground that they are dangerous to persons using the streets. The defendants disputed the plaintiffs' authority to interfere with their wires, denying that they were dangerous to persons using the streets. The plaintiffs' surveyor at Wandsworth gave evidence as to several accidents to persons from the overhead wires which had come to his knowledge, including one which occurred at Islington, when a man was caught and killed by a wire that was blown down in a storm. All the cases of which the witness was able to speak had arisen either by accident to the telephone or telegraph poles, or to trees falling on the wires when blown down by the wind, excepting two, in which the accidents were caused by the wire breaking without the supports being struck. The wires at Putney were raised about thirty feet above the streets, but in some open spaces the height was only about twenty feet. They were made of galvanised iron or phosphor bronze, and were generally attached to house chimneys. They were in some instances taken across the streets obliquely with long spans between the supports. When they were blown down they fell sometimes with great violence, the wire in one case catching and becoming firmly twisted round a lamp post. In answer to Mr. Justice Stephen, the witness expressed his belief that if the wires were taken across the streets at right angles and secured on both sides, so that at these points they would not be affected by accidents occurring elsewhere, the danger would be greatly decreased. The plaintiffs' surveyor for Streatham and Tooting, and other witnesses, gave similar evidence, and the learned judge said the main question seemed to be whether the suspension of great lengths of wire across the road was dangerous. There was some evidence of the wires breaking down by reason of the wind, and if so that was a real danger. Counsel for the defendants submitted that to entitle the plaintiffs to succeed there must be a substantial nuisance, and that in this case there was no real danger. They called the defendant company's engineer and other witnesses in support of that view. The engineer said the length of the wire at Putney was about three-quarters of a mile, and that the greatest span was 105 yards. The breaking strain of the galvanised iron wire was between 600lb. and 800lb.; that of the phosphor bronze between 250lb. and 280lb. The company had little short of 10,000 miles of wires erected throughout the metropolis. The wires and attachments at Putney were in proper condition, and there was not the slightest danger to the public in the streets. There would be nothing gained by making any alteration. He had never known of any fatal accident to any individual by the breaking of any of the company's wires, excepting the Islington case and one somewhere about Blackfriars Bridge.—The learned judge said the only question before him was that which related to Putney. He was not going to decide the whole question with reference to all the wires.

On Tuesday Mr. Justice Stephen delivered a written judgment in this important case. According to *The Times* his lordship said the facts of the case were these:—The United Telephone Company is a joint stock company, not incorporated by any private Act. They lately erected for a private person a telephone wire connecting two of his places of business in Putney, and supplied it at each end with proper telephonic apparatus. The wire and the instruments are the property of the company and are maintained by them, their use being regulated by a contract between them and their customer. The wire is attached at eleven different points to chimneys, and is carried at several places for considerable distances over highways in the district. At one place it passes over the High-street in Putney at a very obtuse angle and some 30 feet above the ground. At this point the span from point to point of its attachments is about 143 yards, the greater part of which is over the street. The plaintiffs are the Wandsworth Board of Works, and by the Metropolis Management Act of 1855 (18 and 19 Vict., chap. 120, sec. 96) all streets being highways are vested in them and are under their control. The action is for an injunction to restrain the defendants from retaining the wire, without the plaintiffs' consent, in the position in which it is now placed. They put their case upon three distinct grounds, viz.—In the first place, they contend that the defendants are a company subject to the conditions of the Telegraph Act (26 and 27 Vict., chap. 112, sec. 12), and are as such forbidden to place a telegraph wire over, along, or across a street or public road without the consent of the body having the control thereof. In the second place, the plaintiffs said that as owners of the soil they had an absolute right to prevent the defendants from suspending wires over their road, upon the principle that the air above the road was as much theirs as the road itself. Again, in the third place, they said that these overhead wires were a nuisance, and exposed the persons using the street to danger. The first of these arguments, his lordship said, turned upon the construction of the Telegraph Acts, and was put as follows:—The Telegraph Act of 32 and 33 Vict., chap. 73, sec. 12, is incorporated with that of 31 and 32 Vict., chap. 110, which itself is incorporated with that of 26 and 27 Vict., chap. 112. Thus the Telegraph Act of 1869, 31 and 32 Vict., chap. 110, is incorporated with that of 1863, 26 and 27 Vict., chap. 112. But in the Act of 1869 telegraph company is defined to mean "any corporation, company, or person for the time being engaged in transmitting, or, by any instrument, incorporated to transmit, telegrams within the United Kingdom;" and in the case of "The Attorney-General *v.* the Edison Telephone Company" it was held that a telephonic message is a telegram. Therefore a telephonic company must be a telegraphic company, and as such is within the Act of 1869 regulating such companies. This being so, it is also under the 1863 Act, and the 12th section thereof applies to it. To appreciate this argument it is necessary to look at the objects of the three Acts. That of 1863 is intended principally to abbreviate legislation respecting telegraph companies authorised by Parliament. That of 1868 gives the Postmaster-General all the powers of a telegraph company under the former Act, and enables him to purchase on certain terms, set out in the Act, the undertakings of the various telegraph companies. The Act of 1869 gives the Postmaster-General a monopoly of telegrams (which has been held to extend to telephonic messages also), &c.; and no doubt this Act would operate to restrain the defendants from sending telephonic messages unless licensed so to do by the Postmaster-General. But it does not put private companies for telegraphic purposes into the same position as telegraphic companies authorised by Parliament. On the contrary, the short result of all the Telegraph Acts read together is to make the Postmaster-General the only telegraph company in England, and to give him all the powers for the erection of telegraphs which were by the Act of 1863 intended to be conferred on private telegraph companies incorporated under private Acts. The defendants are simply a joint-stock company licensed by the Postmaster-General to carry on business, from which they would, but for such license, be restrained by the Act of 1869. But it is clear to me that they have none of the powers of a company under the Act of 1863, and that this, the first argument of the plaintiffs, fails. The second argument is that the effect of the Metropolis Management Act of 1854 is to give the plaintiffs the same right to prevent a wire being stretched across the roads at any height as a private person has to prevent such a wire being suspended over his field or garden. This depends upon the effect put upon the words of the Metropolis Management Act of 1854. The words are—"All streets being highways, the pavements, stones, and other materials thereof, &c., shall vest in and be under the management, &c., of the vestry or district board of the parish in which such roads are situate." The interpretation of words almost

Digitized by Google

identical to these, his lordship, continued, has been considered in several reported cases, particularly in "Coverdall v. Charlton" (3 Q.B.D., 376, and on appeal in 4 Q.B.D., 104). This case is recognised and followed and explained in "Rolls *v.* St. George's, Southwark" (14 Ch. Div.). His lordship, having recited the words discussed in these cases, said that they were held to vest the streets in the local board of management in whose district the streets are. The effect of those decisions appeared to be that the words used in the Public Health Act (which in all important particulars are identical to those of the Metropolis Management Act) give not only the management and control of the streets to such authorities, but even the property in the streets, for all purposes of such management and control. Lord Justice Brett in the above case says (4 Q.B.D., 121)—"Street means more than the surface; it means the surface and so much of the depth as is or can be used not unfairly for the ordinary purposes of a street.". Again, Lord Bramwell upon the same point says in effect, his lordship pointed out, that the local authority owned not only the surface of a street, but the soil to such a depth or thickness as might be necessary in carrying out any alterations, improvements, &c., that could possibly be or become incidental to a street as a street. Lord Bramwell further contrasted this limited view with the wider view in which it might mean that a man acquires property *usque ad cœlum* and to the centre of the earth. His lordship then continued that it seemed clear to him that the present case must be decided on these principles. The case referred to does not decide the extent of a street upwards; it merely limits and defines its extent downwards. It does so, however, upon grounds which appear to me to apply equally in either direction. If it can be shown that the management and control of a street requires some control of the air immediately above it as well as over the ground immediately below it, it seems to follow that the vesting of the street itself in the district board must involve property in part of the air above the surface of the street as well as property in part of the soil beneath it. Now, it is self-evident that the air above a street may be dealt with in such a way as to affect the safety and comfort of the street; as, for instance, if electric wires were stretched across it so as to stop or interfere with the traffic, such a case might no doubt be dealt with as a nuisance. But could it not equally be treated as a trespass? So long as the wires are at a height which interferes actually with the traffic the question is unimportant. But when they are supended as in the present case it becomes most important. His lordship then discussed briefly the evidence on the facts of the case, and continued:—Upon the whole, though I cannot say that absolutely no danger arises from the position of the wires, I do not think, apart from the question of trespass, that it would form an indictable nuisance. If it had been erected with the consent of the district board, and had been indicted by one of the inhabitants as a nuisance at common law, I should not have hesitated to direct a jury that there was no evidence of such a nuisance as would justify a conviction. This being so, the whole question in the case appears to me to be whether or not the street vested in the district board to such an extent above the ground that the suspension of the wires over it entitles them to an injunction. I was at first of opinion that it did not, and that the case resembled that of "The Wandsworth District Board *v.* London and South-Western Railway Company." His lordship having reviewed and distinguished that case from the present one, continued:—It seems to me that Parliament intended to give the district board proprietary powers over the street both upwards and downwards, in order to give them the power of judging of the expediency on public grounds of permitting or prohibiting various acts from time to time affecting the streets, and which, though not perhaps actual nuisances, might yet be considered by the public undesirable innovations. His lordship, having added a few general remarks, concluded his careful and elaborate judgment in these words:—For these reasons I give judgment for the plaintiffs in the terms of their statement of claim, with costs. But as the case is one of such importance, and will no doubt be considered further, and as I think the wire causes no appreciable annoyance or danger to the highway, this injunction is not to be enforced until after the hearing of the appeal, if the defendants do appeal from this judgment.

The United Telephone Company v. the London and Globe Telephone and Maintenance Company.

This case, which was tried before Vice-Chancellor Bacon, was for an injunction to restrain the defendant company from infringing the plaintiffs' patent. The patent, which was described in the pleadings as Blake's patent, was granted on the 20th January, 1879, to William Robert Lake, who in January, 1880, assigned his rights to Francis Blake, from whom in May, 1882, it was purchased by the plaintiff company. The patent was for an improved telephonic transmitter, the principle of which consisted in a self-adjusting apparatus for holding the diaphragm of a telephone by means of springs, and for regulating and modifying the variations of pressure between the two electrodes of the circuit of a telephone. The plaintiffs charged that the defendant company had in their possession a large quantity of telephonic apparatus manufactured according to, or only colourably differing from, the inventions comprised in Blake's patent, and in particular that they had recently acquired a large number of Blake transmitters. They claimed an injunction against the defendants, their servants, agents, and workmen, against manufacturing, selling, supplying, letting on hire, or using any of the said telephones or telephonic apparatus which infringed, or were only colourably different from the plaintiffs' patent. They also asked for the delivery up to them of such apparatus, for an account of profits, and damages. The case for the defence was that in May, 1882, the Attorney-General had, on the application of the plaintiffs, granted his fiat allowing the plaintiffs to disclaim certain parts of the specification of a patent granted to Mr. Edison which had been decided by Mr. Justice Fry to be bad. The fiat was granted on condition that no proceedings for infringement should be taken by the plaintiffs against the defendant company and others for using any instruments of the class included in the disclaimer. In June, 1883, the Attorney-General made an award exempting the defendants from any proceedings in respect of the 800 instruments which were the subject of the present action. The mounting of the electrodes in these instruments was admitted to be in accordance with Blake's patent; but in no other respect was the patent infringed. The instruments were lying unused in the defendants' possession. The defendants also denied the validity of the patent. In November, 1883, they offered to remove from each of the 800 instruments every part which constituted an infringement of the patent.

Mr. Theodore Aston, Q.C., Mr. R. E. Webster, Q.C., and Mr. Moulton for the plaintiffs asked for an injunction in the terms above stated, and that the instruments might be destroyed or delivered up to them. They would have been perfectly satisfied if the defendants had undertaken to export the instruments.

Mr. Hemming, Q.C., and Mr. T. M. Goodeve urged, on the authority of "Minter *v.* Williams (4 "Adolphus and Ellis," 251) and of "Noble's Explosive Company *v.* Jones ("Law Rep.;" 8, App. Cases 5)," that mere possession did not constitute an infringement, and that manufacturing or selling or using had to be proved in order to give a cause of action. The proceedings before the Attorney-General and the fiat also precluded the plaintiffs from the remedy which they sought. It was the plaintiffs' duty to have brought the Blake patent before the Attorney-General, so that the questions might have been dealt with then.

Mr. Moulton, in reply, said that as the fiat of the Attorney-General had nothing to do with the Blake patent, and only dealt with Edison's patent, it had no application to the present case.

The Vice-Chancellor said that the defendants were in possession of certain instruments which they practically confessed, and which were proved beyond the possibility of a doubt to be an infringement of the plaintiffs' patent. That in itself gave the plaintiffs a right to the injunction which they asked. The cases cited by the defendants had no application to the present, and the decision in "Noble's Explosives Company *v.* Jones" was founded upon totally different grounds. There was no force in the contention that the Attorney-General's fiat disposed of the question. The Attorney-General, acting in his judicial capacity, dealt only with the Edison patent, and permitted the plaintiffs to lodge a disclaimer of the Edison patent. But he had no authority to make any order with respect to the Blake patent, which was not before him. It turned out that defendants had 800 instruments which were an infringement of the plaintiffs' patent, and they attempted to excuse that possession on the untenable ground of the Attorney-General's fiat. They also stated that they had no intention to use the instruments. If that were so the injunction would do them no harm. The admission that the mounting of the electrodes was in accordance with the specification in Lake's patent of January, 1879, and the offer to remove from the instruments all such parts as infringed the plaintiffs' patent rights was an admission of the whole of the plaintiffs' claim. The plaintiffs therefore were entitled to the fullest protection he could give them. He did not, however, see his way to ordering a delivery to the plaintiffs of the offending instruments, but he would grant an injunction.

Mr. Hemming urged that the offer of last November to dismantle the instruments and keep them dismantled would have given the plaintiffs all they asked. He therefore asked that the defendants might have their costs since that offer, or at all events that no costs should be given.

The Vice-Chancellor said that Mr. Hemming always died hard, but he could not forget that the plaintiffs offered to allow the defendants to export the instruments. The defendants must pay the costs of the action, and the injunction must go in the terms asked.

Muir and Company v. The Anglo-American Brush Company.

In this case Mr. Ambrose, Q.C., Mr. Bigham, Q.C., and Mr. J. A. Hamilton, appeared for the plaintiffs; Mr. Gully, Q.C., and Mr. Collins, Q.C., for the defendants. Messrs. Muir and Co., engineers and toolmakers, Manchester, are the plaintiffs; the defendants are a limited company. The defendants ordered from Messrs. Muir a facing and boring machine, intended to be used in the production of dynamo machines. When the machinery was completed, and an intimation had been given that it was ready for delivery, the defendants refused to accept it on the ground that the machine had not been supplied within the time that it ought to have been, according to the understanding which was entered into when the order was given. The plaintiffs maintained that no specific time was ever fixed during which the contract was to be completed, and that the machine in question (in the manufacture of which a large amount of skill and care were needed) was completed in as short a time as was possible for the work to be done satisfactorily. The matter at issue has been thrice before a jury. On the first occasion the jury returned a verdict for the plaintiffs. A new trial was afterwards obtained by the defendants. On that occasion the jury were unable to agree, but Mr. Justice Butt, who heard the case, entered a verdict for the defendants on a point of law. The plaintiffs afterwards carried the matter to the Court of Appeal, the result being that the Master of the Rolls (Lord Justice Brett) ordered another trial on the ground that there was no question of law on which a verdict for the defendants ought to be given, the only question to be determined being whether the machinery was completed and delivery tendered within a reasonable period after the order was given. After numerous witnesses had been examined the jury consulted together for a considerable time in private, and returned a verdict for the full amount agreed upon, £736.—Mr. Gully applied that execution might be stayed in order that the matter might be taken before a superior court.—Mr. Ambrose opposed the application, and stated that

Digitized by Google

that was the second time a jury had found in favour of the plaintiffs. He thought under these circumstances it was not advisable that execution should be stayed.—Mr. Justice Day said he saw no reason, looking at the previous history of the case, why he should not consent to stay execution. There could be no very great hurry in the matter; execution would therefore be stayed.

Submarine Cables Trust.

The thirteenth ordinary annual meeting of the certificate holders in this Trust was held at the offices, 66, Old Broad-street, on the 13th inst., under the presidency of the Most Hon. the Marquis of Tweeddale.

The SECRETARY (Mr. Lewis Wells) read the notice convening the meeting and the minutes of the last meeting, and the report of the directors was taken as read.

The CHAIRMAN: Before offering a very few remarks on this occasion I think it right to say that Mr. Pender, one of our trustees, and occupying the chair on these occasions, is absent at this moment, as he is with a deputation to the Postmaster-General with respect to certain matters connected with telegraph business. The accounts which have been submitted to you show that the revenue of the past year amounted to £23,991, against £22,064 in the previous year, being an increase of £1,927. That is due to the dividends on our investment in the Anglo-American and the Eastern Extension stocks being increased. In the one case the difference is as between 3¼ per cent. and 2¾ per cent., and in the case of the Eastern Extension Company the increase is ½ per cent. You are aware that a competition is threatened in respect to the Atlantic cables, and no doubt that competition will influence the receipts of these companies directly, and therefore, indirectly, the receipts of this Trust. It is not for me to express any opinion as to how far that will be the case, but it is satisfactory to us to be able to look forward to increased receipts from other quarters—from the Eastern, Eastern Extension, and other companies in which we are interested, which will enable us, with the considerable sum of £3,943, which we now carry over, to meet our engagements in the future. I do not think there is anything more to be said with respect to the report, but if any gentleman would like to ask any question on any doubtful point I should be happy to answer him. I now beg to move "That the report and accounts now submitted to the certificate holders be received and adopted."

Mr. PENDER, M.P. (who had entered the room in the course of the chairman's remarks), seconded the resolution, which was carried unanimously.

On the motion of Mr. LAMONT, seconded by Mr. LUCAR, Messrs. John G. Griffiths and John Gane were re-elected auditors for the current year.

A SHAREHOLDER inquired whether, in view of the Trust being so small and compact, the certificates could not be registered in case of robbery or fire.

The CHAIRMAN: This question has already been before us, and difficulty arises from the fact that we do not know who the certificate holders are. You mean that the holders who wish to have them registered should have the means of doing so?

The SHAREHOLDER assented.

The CHAIRMAN: We will again consider the matter, and if it is feasible and can be done at no great cost, it may possibly be done, if it is the general wish.

The SECRETARY stated that it would involve a good deal of expense, and the question was, was it worth while incurring that expense?

On the motion of Mr. LAMONT a vote of thanks was passed to the chairman and directors, and

The CHAIRMAN having acknowledged the compliment, the proceedings terminated.

NOTES.

THE SOUDAN.—Telegraphic communication is now restored as far as Debbeh.

ELECTRIC LIGHTING IN PARIS.—The Cercle des Arts Libéraux is lighted by the Edison system.

CENTRAL NEWS v. EASTERN TELEGRAPH COMPANY.—A new trial will be moved for in this case.

THE TELEPHONE IN GERMANY.—Merchants in Mannheim are crying out against the high rates for telephone subscriptions.

ORIENTAL TELEPHONE COMPANY.—Colonel G. E. Gouraud has been elected chairman of the board of directors of this company.

ELECTRIC LIGHTING IN WASHINGTON.—The Edison Company are to light the Government printing office at Washington, U.S.A.

INDIA RUBBER, GUTTA PERCHA, &c., COMPANY.—This company's Bill was read a second time in the House of Commons on Wednesday.

ERRATUM.—In Mr. Kapp's article on "Dynamometers," published in our last issue, Mr. Smith's initials should be "F. J.," and not as therein printed.

UNDERGROUND WIRES IN CHICAGO.—A conduit is to be laid through Chicago to accommodate about sixty wires for the Bankers' and Merchants' Telegraph Company.

DEATH OF MR. TRABUE.—The death is announced of Mr. George W. Trabue, general superintendent of the Southern Division of the Western Union Telegraph Company.

CYCLONE IN BRITISH BURMAH.—On Monday a cyclone passed over Akyab, causing considerable damage to property and shipping, and interrupting telegraphic communication.

WAS THERE A LIGHTNING CONDUCTOR?—During a severe thunderstorm in Calcutta recently a jute warehouse was struck by lightning, and property to the extent of 70,000r. destroyed.

ELECTRIC LIGHT ON STEAMERS.—The Canadian Pacific Railway Steamers "Arthabasca," "Algoma," and "Alberta" will be lighted by the Canadian Edison Electric Light Company of Hamilton.

THUNDERSTORM.—During a severe thunderstorm which occurred at Pontardawe, South Wales, recently, the church and an adjoining house were considerably damaged, the windows being nearly all smashed.

TELEGRAPHIC RECEIPTS IN FRANCE.—The receipts from the telegraphs in France for the first quarter of this year amounted to 8,397,100 francs, or about 663,400 francs less than the estimated receipts.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended May 15 are £2,959, as compared with £3,368 in the corresponding period of 1883.

THE LALANDE-CHAPERON BATTERY.—This battery is now to be seen at work at the offices of Mr. Hugh A. Fergusson, 31, Lombard-street, E.C. We shall shortly give a detailed description of it with illustrations.

APPOINTMENT.—We understand that Mr. Henry C. Graham, late superintendent in Devon and Cornwall to the United Telephone Company, has been appointed manager of the Electric Apparatus Company, of Charing-cross.

TELEGRAPH TARIFFS.—On Wednesday evening Lieut.-Col. Webber, C.E., read a paper on this subject before the Society of Arts. He supported the introduction of a sixpenny tariff. We shall hope to print the paper in our next issue.

LIVERPOOL ELECTRIC SUPPLY COMPANY.—The directors of this company have, out of the profits of the past year, paid a dividend at the rate of 5 per cent. per annum, and have carried forward a similar amount to the current year's account.

ELECTRIC LIGHTING IN ST. LOUIS.—The Custom House and Post Office at St. Louis, U.S., are to be lighted by the United States Electric Lighting Company. The plant will consist of 30 Weston arc lamps and 750 Maxim incandescents.

PROVISIONAL ORDERS.—The Electric Lighting Provisional Order Bill (No. 3) was read a second time in the House of Commons on Monday. The Electric Lighting Provisional Order (No. 2) Bill was read a second time in the House of Lords on Tuesday.

NOTICE OF REMOVAL.—Messrs. Newton and Son, patent agents and mechanical draughtsmen, have removed from their old premises, at No. 66, Chancery-lane, where they have been for nearly seventy years, to new offices at 6, Bream's-buildings, Chancery-lane, W.C.

A TELEGRAPH CLERK TAKEN PRISONER.—*The Times* correspondent at Alexandria telegraphed on the 19th inst. that Signor Cuzzi, a telegraph clerk lately stationed at Berber, and an Italian subject, had been captured by the rebels at Eshrara, some fifty miles from Berber.

ELECTRIC LIGHTING IN JAVA.—A correspondent in Java writes that the palace of Prince Manko-Negoro at Soerakarta is lighted by 46 Swan lamps and five Siemens arc lamps. The current is conducted from the machine room by an underground cable about one mile long.

THE POST OFFICE AND THE TELEPHONE.—In the House of Commons on Monday, Mr. Gray gave notice that he would on the vote on account call attention to the postal arrangements between England and Ireland, and to the attitude of the postal department with respect to telephonic communication.

TO BE WOUND UP.—A petition for winding up the South Kensington Mutual Electric Lighting and Supply Company was presented to the High Court of Justice on the 19th inst. by Messrs. Burchell and Co., of the Sanctuary, Westminster, S.W., and will be heard before Mr. Justice Kay on the 30th inst.

THE HOCHHAUSEN DYNAMO.—We are informed that Mr. H. Edmunds, of 2, Victoria-mansions, S.W., has made arrangements at his factory in Halifax for the manufacture of the Hochhausen dynamos, &c., under the superintendence of Mr. P. J. Charles, late foreman of Messrs. Emmerson and Murgatroyd's works.

TELEPHONE WIRES IN PHILADELPHIA.—The latest from Philadelphia states that the manager of an insurance company gave orders for thirty telephone wires which were fixed to the roof of the company's office to be cut and thrown into the street. The orders were carried out. It remains to be seen what the telephone companies will say.

THE TELEPHONE IN THE SCILLY ISLANDS.—The house of Mr. Smith-Dorrien, "Lord" of the Scilly Isles, situated on the Island of Tresco, is connected by telephone with the house of his steward, which is on St. Mary's, another

Digitized by Google

island. The distance between the two islands is about three miles, and the line is laid under the sea.

THE TELEPHONE IN AMERICA.—The New England Telephone Company has instruments in 472 towns in the New England States, and has 109 exchanges at work. In Boston it has 2,386 subscribers, Lowell 959, Lynn 501, Manchester 403, Portland 727, Salem 320, Springfield 588, Worcester 784. The total number of subscribers to the company's system is 17,820.

EARTHQUAKES IN TURKEY.—During the last fortnight there have been several shocks of earthquake on the Asiatic shore of the Sea of Marmora. On Monday an unusually severe one did a great amount of damage to the villages on the peninsula of Cyzicus. A correspondent of a daily paper states that many houses were destroyed, though the loss of life is nowhere estimated at beyond twenty.

CROMPTON V. MAXIM-WESTON COMPANY.—In all probability for the first time in the history of litigation a dynamo machine was to be seen in No. 8 Court, Queen's Bench Division, on Thursday last, when this case was put down for hearing. Fortunately the litigants agreed to settle their differences out of court. We wish that all litigation connected with electrical matters could be as readily settled.

NEW PAPER.—We have received a copy of No. 3, Vol. I., of the *Canadian Electrical News*, which is apparently the last venture in electrical journalism. Although of modest dimensions at present, viz., eight pages, we have no doubt it will soon grow, as the electric light, telephone, and telegraph are making rapid strides in the Dominion. The *News* is published at Montreal and edited by Mr. John Horn.

DEATH OF M. CHARLES BONTEMPS.—The death is announced at the age of 45 of M. Charles Bontemps, of the French telegraph service, which he entered in 1860. He attained the rank of inspecting-engineer, and had special charge of the pneumatic and underground service. He was one of the founders of the French journal *L'Electricien* and a frequent contributor to its columns. He died suddenly on the 6th inst.

TRANSMISSION OF POWER.—Experiments on the transmission of power by means of electricity have lately been carried out at Biel, in Switzerland, by Messrs. Meuron and Cuenod, of Geneva. Water power was used to drive the transmitting dynamo, and the circuit was composed of a copper wire 7mm. diameter and 1,200 meters long. Thury machines were used, and the speed is said not to have exceeded 400 or 500 revolutions per minute.

THUNDERSTORM IN IRELAND.—A fearful thunderstorm passed over Warrenpoint and neighbourhood early on Wednesday morning. The Killowen Roman Catholic chapel, where the celebrated Yelverton marriage was performed, was struck by lightning, and the greater portion of it destroyed. The telegraph wires between Rostrevor and Kilteel were broken, and a large number of sheep which were grazing upon the mountains were killed by the lightning.

FAST SPEED TELEGRAPHY.—Speaking of the recent contest amongst Morse operators in London, the *New York Operator* says:—"We are willing to admit that England can produce as fast operators as we can, but we claim that with their lumbering code of signals as against our rattling combination we can beat them, everything else being equal. We have sworn records of fast Morse sending at the rate of forty two words a minute for sixty consecutive minutes—over 2,500 words in one hour."

THE FURNITURE EXHIBITION.—At this exhibition, which was held in the Agricultural Hall last week, the Anglo-American Brush Company had a D_2 Victoria machine at work, supplying current to 100 of their Victoria lamps in different parts of the hall. Among the stalls illuminated we may mention those of Messrs. Druce, Messrs. Procter, and others. The whole of this installation was successfully worked and carried out by Messrs. Gretton, Thynne, and Co., electrical engineers and contractors.

ELECTRIC LIGHTING FOR MINES.—In 1861 proposals were made to provide an electric light for safety lamps by means of an electro-magnetic apparatus. The first form of electric safety lamp was constructed by Benoit and Dumas. It consisted of a zinc-carbon battery, a Ruhmkorff induction apparatus, and a Geissler tube. This lamp was for a time used in the Saarbrücken mines, but it was too heavy and too fragile, and as, moreover, its illuminating power was comparatively low, its use has been very much limited.—Herr Hoernecke, of Halle, in the *Verhandlungen des Vereins für Beförderung des Gewerbfleisses.*

ELECTRIC LIGHT IN FLOUR MILLS.—Messrs. W. and J. Bairstow, of Keighley, whose mills have been lately reconstructed, have adopted the electric light. The installation consists of one Crompton-Burgin dynamo machine of the self-regulating type, which feeds sixty-two 20 candle-power Swan lamps, 110 volts, which light the mill, boiler and engine houses, and offices. As usual the machine is placed on the ground floor, and is driven from a countershaft at a speed of about 1,450 revolutions per minute. This is the first time the light has been tried in Keighley. The work has been done by Mr. Wilson Hartnell, of Leeds.

FAURE-SELLON-VOLCKMAR ACCUMULATORS.—The Electrical Power Storage Company announce that a reduction has been made in the prices of these accumulators, and that some new types are ready for supply. The ordinary accumulator cell, with either glass or wooden boxes, contains 15 plates per E.H.P., the normal rate of charge being 20 amperes, and of discharge 30 amperes. A stronger pattern, with 13 plates, is also made, having a discharge rate of 26 amperes. Special cells are constructed, with plates of extra strength, for use as regulators for installations on the incandescent system. The company state that the useful E.M.F. of each cell may be taken as 2 volts, although for a short time after charging it is as high as 2·15 volts.

A SIMPLE ELECTRO-DYNAMOMETER.—Signor Bellati substitutes for the needle of a reflecting galvanometer a small cylinder of soft iron, bifilarly suspended in a direction perpendicular to the magnetic meridian, and inclines the vertical coil through which the currents to be measured pass to 45° from this meridian. In point of fact the earth's action is nullified, since the soft iron remains practically perpendicular to the magnetic meridian, and as its magnetism changes its character with the direction of the current the electro-magnetic action always maintains the same sign, like the electro-dynamic action in the electro-dynamometer. A closely-packed bundle of soft iron wires, of ·15m. diameter and 17m. long, may be substituted for a soft iron cylinder.

STRANDING OF THE "RETRIEVER."—A telegram received at Lloyd's from Syra states:—"The Eastern Telegraph Company's steamer 'Retriever' stranded on Saturday morning at North End, Santorin, and her forehold as far as the main tank is full of water, and it is feared bottom badly damaged. Discharging cable ashore to lighten the ship. Wired Syra for

Digitized by Google

assistance. All that is possible will be done to save the ship if the weather keeps fine." A further telegram from Syra states:—"'Retriever' grounded on reef, Cape Mavropetra, Santorin, at 10 a.m. Saturday morning. Fore part full of water. Now discharging cable and using every endeavour to get the ship off." The "Retriever" is an iron screw steamer of 457 tons gross, built at Glasgow in 1879.

TELEGRAPH MATERIALS WANTED.—The Great Eastern Railway Company is inviting tenders for the supply of telegraph materials and india rubber. Forms of tender can be had at the Secretary's Office, Liverpool-street Terminus, E.C., and patterns can be seen at the stores at Stratford, between 10 a.m. and 4 p.m., up to the 29th inst. Tenders to be sent in to Mr. J. Hadfield, secretary, Liverpool-street Terminus, by 10 a.m. on the 31st instant. The North-Eastern Railway Company also require tenders for the supply of telegraph stores during the six months ending December 31. Forms of tender may be obtained on application to Mr. Graves, Telegraph Department, York, and tenders must be sent to the secretary at York, sealed and marked "Tender for Telegraph Stores," by noon on the 29th inst.

ELECTRIC LIGHT IN COLLIERIES.—A most satisfactory and successful electric light installation has just been completed at the Park Pit Ocean Collieries, South Wales. The motive power is supplied by a 6 horse-power Marshall engine, fitted with Hartnell's patent automatic expansion gear, driving a Crompton-Bürgin self-regulating dynamo. There are fifty 20 candle-power Swan incandescent lamps distributed underground and on the surface over the screens, workshops, and engine houses. The novel feature in the installation is the very successful manner in which the bottom of the pit is lighted, and 150 yards of the workings, as far as the main engine roads. The work has been carried out by Mr. J. C. Howell, Llanelly, agent for Messrs. R. E. Crompton and Co., assisted by the officials of the colliery.

THE FRENCH ACADEMY OF SCIENCES.—At the annual meeting of this Academy, held a few days since, the Fourneyron Prize was presented to M. Marcel Deprez, for his experiments on the transmission of power by means of electricity. The Lacaze Prize was awarded to M. Henri Becquerel for his labours in experimental physics. M. Gaston Tissandier received a portion of the Penaud Prize for his experiments on the steering, &c., of balloons by electrical means. It was resolved that the subject of the grand mathematical prize for 1884 should be "The perfecting of the theory of applying electricity to the transmission of energy." This prize consists of a medal valued at 3,000 francs (£120). The subject of the Bordin Prize for 1885 will be "The origin of atmospheric electricity, and the causes of electrical phenomena during storms."

RESISTANCE OF ARC LAMPS.—The ordinary voltaic arc of the lighthouse, according to M. F. Lucas, plays between the points of two Carré carbons of 16mm. diameter, the distance between which is maintained very nearly constant (on the average 4mm.) by the action of a Serrin regulator. In a recent note to the French Academy of Sciences, M. Lucas states that by causing the current sent through the arc to vary between 40 and 75 amperes, and the distance between the points of the carbons from 0 to 9 millimetres, he found the resistance of the arc ζ could be represented by the formula $\zeta = \cdot 40 \text{ ohm} \left(1 - \frac{1}{80 \text{ amp.}}\right)\left(1 + \frac{\epsilon}{1\text{mm.} \cdot 4}\right)$. With a current of 50 amperes and a distance between Carré carbon points of ·004m., the normal state of affairs in the French lighthouse service, the resistance of the arc is found to be ·58 ohm.

ELECTRIC LIGHTING IN THE CANARY ISLANDS.—We learn that it is proposed to light the city of Las Palmas, the capital of the Island of Gran Canaria—and not, as we inadvertently stated in a previous number, of the Archipelago—by means of the electric light. The Spanish Government Engineer of Woods and Forests, Don Clemente Figuera, holds the concession from the Corporation for carrying this proposal into effect, and the machinery and material are now arriving in instalments from France. The first portion of the installation will consist of about one hundred arc lamps, which will illuminate several of the principal streets and squares of the city, and from the success of this it will be decided whether to adopt the electric light as a permanency, and extend its use to other parts of the city, or otherwise. The only artificial illuminating agent at present in use in the streets of Las Palmas is oil, and for a part of each month this is dispensed with in favour of the moon.

INTER-COLONIAL TELEGRAMS.—A request was recently presented to the Postmaster-General of Victoria by a deputation from towns contiguous to the South Australian border, that instead of an inter-colonial charge of 2s. being made for telegrams interchanged between border towns on either side which were only a few miles distant from each other, messages should be transmitted at the same rate as if they had not to be delivered outside the colony—namely, 1s. for ten words. The postal department has since been in correspondence with the South Australian Government on the subject—says the *Colonies and India*—and the Postmaster-General of the latter colony has replied to the effect that it would be difficult to draw a line defining the distance from the border or the particular towns to which the proposed concessions should be extended. In a subsequent communication he states that after giving careful consideration to the matter the Government did not consider the proposed arrangement desirable, and were unable to approve of it.

THE ELECTRIC LIGHTING ACT.—At the last meeting of the St. James's (Westminster) Vestry, the Lighting Committee presented a report recommending, with reference to the St. James's, Westminster, St. Martin-in-the-Fields, and St. George, Hanover-square, electric lighting order, as settled by the Board of Trade, that the Vestry do convey to the Board of Trade an expression of regret that the Board has not seen fit to adopt the Vestry's views with regard to amending Schedule C (sec. 1), by providing that the undertakers may make a minimum charge for 250 units of electricity per annum (equivalent to £7 5s. 10d. per annum), in lieu of a minimum charge of £3s 10s. per quarter, and that the Board be informed the Vestry still entertain a very strong opinion that the power of the undertakers to make a minimum payment of £3 10s. per quarter a condition of supplying electricity will operate with special hardship on small consumers. The committee reported that, with the foregoing exception, they see nothing in the said order appearing to call for special remark.—This was adopted.

UNIVERSITY COLLEGE, NOTTINGHAM. — The chair of engineering in this college is vacant, and applications are invited for the professorship. The professor of engineering will have the management of the college workshops, and must have a practical acquaintance with the ordinary operations of the foundry and fitting shop. He should also have a technical knowledge of electrical engineering. In addition to supervising the practical work of students, he will be expected to

Digitized by Google

conduct classes in mechanical, civil, and electrical engineering, and must be prepared to devote several evenings a week during the winter months to the conduct of classes for artisans. His remuneration will consist of a fixed stipend of £200 per annum, together with half the fees of the workshops and classes in his department, and any Government or other grants earned by his students in examinations. Applications, with testimonials and references, should be sent before June 10, to Mr. S. G. Johnson, town clerk, Municipal Offices, Nottingham, from whom further particulars may be obtained.

Overhead Wires in New York.—The *Scientific American* thinks that if the telegraph and telephone companies in New York are compelled to put their wires underground they will raise their rates in order to cover the extra expense entailed upon them. Our contemporary is of opinion that a plan might be devised by which the wires could be systematically led over the roofs of the houses, without proving a special hardship or annoyance to any one, and thinks it somewhat surprising that no such plan has been considered. It continues:—"There is good reason to believe that, with proper supervision by constituted authorities, the general and indiscriminate scrambling over roofs now indulged in by line men could be avoided in great measure. The unsightly street poles could be done away with, and the wires now strung on them be laid in the same order over roofs of the houses. When damage of any kind resulted, such as injury to a chimney or roof, those who had general supervision over all the wires could readily decide who was responsible for it, and hence who must repair the injury done."

A Curious Experiment.—It is known that if there be a primary circuit comprising a microphone, a Leclanché battery of, say, three cells and the primary wire of an induction coil, and a secondary circuit comprising the secondary wire of such coil, another Leclanché battery of, say, 12 cells, and two metal contact pieces, such as are used for medical purposes, and if two persons each hold a contact piece in one hand, and one of them lays his disengaged and gloved hand on the ear of the other, the latter will hear words that are spoken into the microphone, as if they came out of the other's hand. At a recent meeting of the French Physical Society, M. Hospitalier modified the above experiment by replacing the gloved hand by a piece of ordinary paper. Two persons took hold of the contact pieces as before, and placed their heads together ear to ear, with the paper between, and could hear all that was said at the microphone. Further, holding the contact pieces as before, these two laid their disengaged hands on the ears of a third person, who again heard what was spoken into the microphone, the hands appearing to talk.

International Forestry Exhibition.—The Anglo-American Brush Electric Light Corporation have received the order for lighting the buildings and adjacent grounds of the International Forestry Exhibition, to be held in Edinburgh during the present year. The apparatus which is to be supplied for the purpose will consist of four No. 7 Brush "arc" machines, forty-six of the Corporation Brush-Sellon lamps for indoor use, and fifteen Brush arc lamps, fitted in hexagonal lanterns, for use in lighting the exterior portions of the building and adjacent grounds. The Brush-Sellon lamps are, from their steadiness, admirably suited for indoor illumination. Besides the above apparatus, various parts of the building will be lit by the incandescent light. For this the Corporation are supplying two of their E_2 compound Victoria machines, each capable of maintaining 250 20 candle-power 60 volt lamps. These 500 lamps, the type of which will be the Corporation's Victoria lamp, will be employed for lighting the corridor leading from the main entrance, the refreshment rooms, and other parts of the building where arc lights would be unsuitable.

Electric Lighting in Chicago.—The City Council of Chicago not long since passed an ordinance laying down certain regulations for the running of electric light wires so as to insure some uniformity and to provide against ignorant and careless work. To show how necessary this ordinance was it is only requisite to quote from a report prepared by an inspector sent round by the council to see into this matter. During his visits the inspector reports finding wires insulated with paraffin coverings, sometimes only singly wound, sometimes with a braided envelope; wires of less conductivity by several sizes than that considered safe, smaller by several numbers than that used by any arc light company of the present day; wires with no insulation whatever, nailed to wooden partitions, with iron staples, these latter reaching to and in contact with wire lathing, thus forming a partial ground connection. In several instances wires of as many as two or three sizes were found upon the same circuit. In addition to all this, instances were found where wires were not only naked, or imperfectly insulated, but so near together as almost to touch, and both within close proximity to iron columns, water and gas pipes, and the like.

Electric Gas Lighters.—The stables of Mr. Cornelius Vanderbilt, of New York, are lighted throughout with gas; but as matches are not allowed each burner is provided with an electrical arrangement for lighting it. The current is generated by four "Diamond" carbon batteries, one pole being connected to earth by contact with the nearest gas-pipe, and the other being led in the first place into a primary induction coil. From the coil the wire passes to a clock-mechanism and switchboard, whence the different circuits start. At the burner the wire is connected to a metal ring, which encircles the lava tip, and has a projecting point opposite the slit. On the body of the burner-connection is a spring crank, which bears on one lever a wiping contact piece, and on the other a hanging button. When the button is pulled, with the gas turned on, the electrical circuit is closed by the contact of the wiping spring with the point of the ring on the burner; and on being released, a spark is drawn out, which lights the gas, while the crank falls back out of the way. The lighting current must thus be connected at two points—the switchboard and the burner—before a gas-jet can be lighted. The object of the clock-mechanism is to break the circuit if by accident it should be left connected to earth for more than ten seconds.

Counting Papers.—Mr. George Rosquist, the machinist of the New York *Sun*, is the inventor of an electrical apparatus by which papers are counted and registered as they leave the steam presses. It is simple and complete, and has been in successful use on the *Sun* presses for several months. Unlike the other paper-counting apparatus now in use, which registers the revolutions of the cylinders whether the paper is running over them or not, Mr. Rosquist's apparatus only registers the actual number of impressions made. On the male cutting cylinder of the press is fastened a bowed strip of brass about three inches long and one inch broad. On it is a button which connects with a bell crank, which works a small rod connecting with a circuit switch in a box on one of the cylinder's journals. The switch connects, by wires from a small battery, with an electro-magnetic apparatus constructed on the prin-

Digitized by Google

ciple of the Morse telegraphic instrument. The pressing of the button works the switch, which flies back to its original position when the pressure is removed. This works the bar on the electro-magnetic apparatus, which connects with the register by a lever. The lever moves a geared wheel, which registers either two or four papers, depending on the size of the press. The registers for the double presses register as high as 999,000, and those for the single presses register 99,000. In order to prevent the registering of revolutions of the cylinders when papers are not printed there is a small canal cut into the female cutting cylinder, into which the bowed strip of brass with its button sinks when the canal is not covered by the paper on which the impressions are made. The registers can be placed at any distance from the presses. Those used by the *Sun* are in the office of the superintendent of the paper department, on the floor above the presses.—*Electrical World*, New York.

Change in the Peltier Effect due to Variation of Temperature.—In the recently-issued *Proceedings* of the Royal Society of Edinburgh is a short paper by Mr. A. Campbell upon this subject. Mr. Campbell says:—"The object of this short paper is to give the results of some further experiments made with a view to determine the variation in the Peltier effect due to change of temperature. These experiments are the continuation of a set of similar experiments described in a paper read to the society in summer 1882. The arrangement used was almost exactly the same as that employed in the former experiments, the measurements being made by means of an iron German-silver thermopile bent into the shape of an arch, with the ends about ¼in. apart, and placed so as to almost touch the junctions of the metals whose Peltier effect was to be measured. The neutral points of the various pairs of metals were also measured in the usual way by heating up a junction in oil, plotting the temperature-deflection curve, and from it deducing the neutral-point. According to theory, the ratio of the Peltier effect at temperature t_1 to that at t_2 is determined *solely* by the values of t_1, t_2, and the neutral-point of the metal used; therefore it was not necessary to draw the thermo-electric lines of the metals. As I have no satisfactory measurement of the neutral point of Pb – Arg, in this case the calculated ratio in column V. is from Professor Tait's diagram. In the subjoined table, column I. gives the name of the pair of metals; II. and III. the lower and upper temperatures at which the Peltier effect was observed; IV. the ratio of the Peltier effects at these two temperatures *from the direct measurement;* V. the ratio calculated from the observed neutral-point given in VI.:—

I.	II.	III.	IV.	V.	VI.

Electricity: its Relation to Vital Power.—The *Scientific American* of May 3 contains a short article on this subject, of which the following seem to be the principal points. Vital and nerve forces are assumed to be identical. The question then arises: Is there a relation between electricity and nerve force? Have they anything in common? These are questions of almost infinite importance in relation to the welfare of every human being. The electrical conditions of the atmosphere are totally unstable, changing from hour to hour, and if the force which they represent is allied to our own vital force it is impossible to resist the conclusion that the bearing of these fluctuations on the health of the whole human race must be powerful for good or for evil. It was formerly a common thing to speak of the "electric fluid." This term was used because the mysterious agent could be conducted from one place to another; it would *run* as water does in a pipe; it was produced in one place and run along to another, following certain substances which were called conductors. Nerve force does precisely the same thing. It originates only in the nerve cells, minute microscopic objects, which, however, are in many places grouped into such masses —called ganglia—as to be of appreciable size. These, from their colour, are called the grey matter of the nervous system, while the cords which we know as nerves running to every part are white. These nerves are simply the conductors; they originate nothing, any more than do telegraph wires. Here is the first similarity of nerve force to electricity; it is found in the battery (the nerve cell), and is connected by the wire (the nerve). The second item of similarity is that electricity directly applied to a nerve produces the same effect as an increase of its own force. The muscles are under the control of the will. My mind, for instance, determines to bend my forefinger; the brain cell sends the message by means of the nerve to the appropriate muscle, and my finger is bent. If now, on the contrary, I apply a battery to that same nerve, the finger is at once bent, without my will, or even in opposition to my will. Apparently I send the *same force* from the battery that the brain sent in the other case, and as I can easily make the battery the stronger of the two, the finger is bent even though I determine that it shall not stir. This is one strong proof of the absolute identity of the two forces. Still again, in studying the action and functions of the sympathetic nerve or system, it is found beyond question that the direct application of electricity increases the power of action of the part to which it is applied. It is found, on the other hand, by clinical observations that whatever tends to exalt the nerve force does precisely the same thing; that is, nerve force and electricity produce the same results, as was the case in the previous illustration. It would seem, therefore, that electrical force and nerve force must be identical; but there are, on the other hand, points of discrepancy which must not be neglected. The mode of distribution is widely different. It is a matter of great difficulty to retain electricity after we have produced it. It escapes with exceeding ease, and the most careful insulation will hold it but imperfectly, especially where moisture can reach it. Nerve force, on the contrary, originates among the moist tissues, and passes everywhere freely among them without any tendency to escape from the line of its own moist conductors—the nerves. It is true that this does not prove identity, for it may be only one feature, as yet imperfectly understood, of one out of perhaps several types of electrical energy; and the same remark may apply to the fact that different nerves, which so far as we know are identical in structure, convey nerve force to totally different types. We have nerves of sensation, of motion, of sight, of hearing—of all the special senses. Are these all only distinct forms of electrical action? It seems probable that from all these sources of inquiry we may draw the inference that even if electricity is not identical with our nerve force it is at all events so closely allied with it that electrical changes must surely influence human vitality, either for good or for evil.

SOME RELATIONS OF CHEMICAL CORROSION TO VOLTAIC CURRENT.*

BY G. GORE, F.R.S., LL.D.

The chief object of this research was to ascertain the amounts of voltaic current produced by the chemical corrosion of known weights of various metals in different liquids. The research was also made to throw light upon the conditions which determine the entire conversion of potential molecular energy into external (*i.e.*, available) electric current. The method adopted was to take about six or eight ounces by measure of a corrosive electrolyte, and divide it into two equal volumes in two similar glass vessels. Two pieces of metal of equal dimensions were then cut from the same sheet, cleaned perfectly, and weighed. One of the pieces was employed as the positive plate of a voltaic cell in one of the portions of liquid, and the other as a comparison corrosion sheet in the other portion. The negative metal of the voltaic cell was in nearly all cases a large cylinder of sheet platinum, and surrounded the positive one; in No. 24 it was a large cylinder of lead. The positive and comparison plates were wholly immersed in the separate portions of liquid, except that the former had a narrow exterior projecting strip for connection in a circuit. The current from the cell was passed by means of a small silver anode (½in. by ⅜in.), and a smaller silver cathode (¼in. by ⅜in.) in a third vessel, through a cyanide of silver plating solution containing the least practical proportion of free potassic cyanide in order to obtain the maximum amount of silver deposit.

During each experiment observations were made of any liberation of gas or formation of solid coating upon the plates, and of any other circumstance which appeared likely to affect the speed of corrosion, or weight of the plates, or of the deposited silver; and in any case where any solid coating was found, it was entirely removed after the experiment, and previous to ascertaining the losses of weight by corrosion. After the experiment the plates were well washed and carefully dried between hot sheets of filter-paper before weighing. The metals and liquids employed were as pure as could conveniently be obtained, and distilled water was used for all the solutions. The sample of potassic cyanide usually employed was found by analysis to contain 89·14 per cent. of the actual substance; but that used in Nos. 1, 2, and 90 contained only 81·7 per cent. Nearly all the liquids were employed at the atmospheric temperature, and in every case except Nos. 40, 41, 56, and 57, the comparison sheet was used.

As the proportion of silver deposited to the amount of external current generated, and therefore also to the amount of positive metal corroded, varied to a very small extent with the density of the current at the cathode in the depositing solution (*see* "Electrolytic Balance of Chemical Corrosion," *Proceedings* Birm. Phil. Soc., Vol. III., 1883, pp. 278-304), the amount of cathode surface was usually varied according to the apparent strength of the current and rate of deposition, being smaller as the current was less.

The degrees of electromotive force were measured by the aid of two thermo-electric batteries, each consisting of about 300 pairs of iron and German silver, together with a Clark's Standard cell (see *Proceedings* Birm. Phil. Soc., Vol IV., Part 1; also *The Electrician*, Vol. XII., p. 414).

The accompanying series of tables exhibit the results. In the tables the number of square inches given includes in each case both surfaces of the immersed portion of the positive metal; and similar with the comparison plate. The losses of the plates and the weight of deposited silver are in every instance expressed in grains, and the rates of loss of the positive plate are given in column 6 in grains per square inch per hour. If the whole of the corroded portion of the positive metal produced external current consistent in amount with the atomic weights and valencies of the metals as given in the tables, and if that amount be called 100, then the proportions of such current actually obtained in the experiments are those given in column No. 9. The quantities of substance mentioned in column No. 1 were in each case per ounce of water.

Only those results which appeared reliable are inserted in the tables; many uncertain ones are omitted. In some cases coatings of solid matter formed either upon the positive or comparison plates, or gas was evolved by the plates. Cases in which the coatings could not be perfectly removed were rejected. With magnesium in solutions of ammonic, potassic, or sodic chloride, potassic bromide or iodide, a solid deposit containing black suboxide of magnesium formed upon the positive plate only (see *Proceedings* Birm. Phil. Soc., Vol. IV.) And with aluminium in solution of iodic acid a compound of iodine was absorbed, and both the plates increased about 16 per cent. in weight (*ibid.* Part 1., p. 65). In seven cases (Nos. 6, 7, 14, 28, 65, 67 and 81), from causes which were not very apparent, the comparison sheet lost weight more than the positive one. The considerable degree of variability of rate of ordinary corrosion detracted greatly from the usefulness of the comparison plate.

The results show that the proportion of loss of the positive plate by "local action" to that by corrosion attending external current varied greatly in different cases; with silver in a dilute solution of ferric sulphate the latter only amounted to about 1·3 per cent. of the total corrosion, whilst with tin in weak hydrochloric acid it was as much as 95·25 per cent. In no instance was the whole of the metal dissolved by "local action," and in no case was the whole of the corrosion attended by external current.

The amount of corrosion of the positive plate was in nearly all cases greater than that of the comparison one. Six cases were selected from the table, in which the apparent corrosion of the latter sheet was the greatest, and some trouble was taken to ascertain by experiment whether either of these was a real one. After varying the conditions of the trial in several ways with pure copper in a mixture of 50 minims of pure nitric acid per ounce of distilled water it was found that in this instance the comparison plate was always corroded the fastest.

As the amount of corrosion of the positive plate was in nearly all cases greater than that of the comparison one, and the proportion of gas to corrosion was also frequently less with the former than with the latter, a solid deposit was usually more readily formed on the positive plate than upon the comparison one, and the chemical products were not always exactly the same upon the two plates. An instance of this kind occurred with amalgamated silver in a solution of potassic cyanide; the positive plate alone became brown. As the chemical products of "local action" and of corrosion attended by external current are usually the same; in cases where they are different, though resulting from the same materials, the total expenditure of potential molecular motion would probably be different, because the quantities of residual molecular energy of the ingredients would not be the same.

The proportion of corrosion of the positive plate accompanying external current to that produced by "local action" may be approximately arrived at, either by deducting from the total amount of corrosion of that plate the loss by weight of the comparison one, or by calculating from the quantity of deposited silver, together with the atomic weights and valencies of the positive metal and of silver, the amount of the positive metal required to produce the current. Each of these methods, however, is imperfect; the second is usually much the least so. In several cases, by employing the former one, the amount of deposited metal was found to be nearly equivalent to the amount of corrosion accompanying external current, after making allowance for a small deficiency of deposited silver caused by a portion of the current traversing the free potassic cyanide in the depositing liquid.

That the external current affects in some cases the amount of "local action" was shown by the following experiment:—A sheet of platinum and one of ordinary zinc, not connected together, were partly immersed in dilute sulphuric acid, until a moderate stream of gas arose from the zinc. On now connecting the two plates together by means of a wire, the stream from the zinc was conspicuously diminished. The contact of a negative metal with the positive one usually increased the total loss by corrosion, whilst it commonly decreased that caused by local action.

The results contained in the table further show that the proportion of corrosion attending external current (as measured by the amount of silver deposited) to that by "local action" depends upon several conditions:—1st, upon the kind of metal; thus it was usually greater with cadmium (average 75·63 per cent.) than with copper (30·33 per cent.). 2nd, upon the kind of liquid; it was greater with solution of potassic cyanide (average 63·27 per cent.) than with dilute nitric acid (31·14 per cent.). And 3rd, upon the degree of concentration of the liquid; a greater strength of solution frequently increased, and as frequently decreased, the proportion of corrosion accompanying external current to that by "local action." A variation of kind of metal also was attended by a greater change in the proportion of such corrosion than a variation of kind of liquid. This latter circumstance is consistent with the view that the potential molecular activity of metals is usually greater than that of electrolytes. (*See* "Relations of Heat to Voltaic and Thermo-electric Action," *Proceedings* Royal Society, No. 228, 1883, Vol. 36, p. 50; also *The Electrician*, Vol. XII., p. 277.)

The effect of amalgamation of the plates upon the proport tions of those actions to each other was usually distinct. In

Digitized by Google

ten cases it increased, and in five decreased, the proportion of external electric current to "local action" currents. With tin in dilute nitric acid it greatly increased the proportion of external current to total corrosion, whilst with lead in a solution of potassic hydrate it had the opposite effect. It appeared to increase that proportion the most in cases where much hydrogen was evolved, as with zinc in dilute sulphuric or hydrochloric acid. In seven instances it increased, and in nine decreased the rate of total corrosion of the positive plate, and the amount of the latter was nearly five times that of the former; and in seven instances it increased and in eleven decreased the loss of weight of the comparison plate, and the amount of the latter was fourteen times that of the former.

The rate of total corrosion of the positive plate appeared to be related to the degree of electromotive force. By comparing together columns 4 and 6 of the table it was found that the instances of least electromotive force and lowest rate of corrosion coincided in the case of magnesium, zinc, tin, aluminium, iron, nickel, and copper; and of greatest coincided in the case of lead and copper. With magnesium the order of electromotive force was almost the same as that of total corrosion, and with copper it was partly so. No. 24 in the table further illustrates the influence of decreased electromotive force.

The simple and chief explanation of the great variation in the proportion of corrosion by "local action" to that attended by external electric current appears to be difference of electric-conduction-resistance. Where there is no external current, and the external resistance is infinite, as in cases of deposit of metal or hydrogen by simple immersion, the whole of the electricity flows through the local circuits, and deposits its complete equivalent of metal, hydrogen, or both, on the negative parts of the positive plate; but when the external resistance is least, and the resistance to circulation of local currents is greatest, nearly the whole of the electricity passes through the external circuit, and nearly the whole of the deposition of hydrogen or metal occurs upon the negative plate. In either case the full equivalent of electricity circulates. With zinc and platinum in dilute sulphuric acid the "local action" was diminished by closing the circuit. By diminishing also the external resistance in relation to that in the battery by the employment of two voltaic cells in series instead of one (see No. 23) in a separate experiment the proportion of silver deposited was increased from 90·02 to 93·83 per cent. of the theoretical quantity.

Rate of corrosion depends chiefly upon the particular combination of metal and liquid, and is limited by the substance of weakest molecular action. Thus the rates of corrosion of magnesium in solution of potassic cyanide (or in dilute hydrofluoric acid) and in dilute sulphuric acid are just the opposite of those of aluminium in the same liquids. Whilst magnesium dissolves very slowly in the former liquid and very rapidly in the latter, aluminium does just the reverse (*see* "Relations of Heat to Voltaic and Thermo-electric Action," *Proceedings* Roy. Soc., Vol. XXXVI., p. 50, 1883); therefore either a difference of metal or of liquid in this case reverses the effect. Two of the most extreme cases of difference of rate of corrosion observed at 60° F. were aluminium in 3½ per cent. pure hydrofluoric acid, and in very dilute sulphuric acid.

FROM AMERICA.—The Edison Electric Company at Brockton is trying the experiment of out-door lighting, by placing clusters of three 32 candle-power lights on a couple of street corners. The lights are suspended on wires about 30 feet from the ground. It is thus intended to demonstrate that street lighting by this system is possible.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending May 16, 1884, were £2,751, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended 16th May amounted to £3,499.

LITERATURE.

A Practical Treatise on Electric Lighting. By J. E. H. GORDON, B.A. [London: Sampson Low, Marston, Searle, and Rivington, 188, Fleet-street.]

In 1878, carrying introductions to the late Count du Moncel, the writer went to Paris to see the world's fair—in the shape of an international exhibition. Electricity did not play a very important part in that exhibition, but Paris, with the aid of Jablochkoff, showed the nations that a more brilliant light than gas could be given in her streets. Talk as we may, dispute as we will, to Paris and to Jablochkoff do we owe the germs that have grown so rapidly till the whole civilised world is permeated with thoughts about the electric light. The progress made in the art of electric lighting in six short years is far greater than the progress made in a similar period by any other application of science. Midway between then and now came the Electrical Exhibition at Paris in 1881, when the world first realised the probabilities centering around the new method of lighting. The period which has elapsed since 1878 has witnessed a new literature—the literature of electric lighting. If we may venture to entertain an opinion, a proceeding which is somewhat novel in these days when mankind follows the example of "parrots" and jabbers the same old tale over and over again, we may say that while Fontaine's book introduced a certain class of literature, Gordon's book may be expected to introduce another class. In the one case we had milk—now we have meat.

Before proceeding to indicate the contents of this book we may call attention to some remarks in the preface. Mr. Gordon says:—"In October, 1881, I wrote in the *Quarterly Review*, 'The day will come when gaslight will be as obsolete as wooden torches, and when in every house the incandescent lamp will have replaced the gas jet.'" He continues "In this, the darkest hour of electric lighting, when failure after failure has occurred, when company after company has become bankrupt, I unhesitatingly repeat this—I will not say opinion, but conviction, only adding to it my further conviction that the day of universal electric lighting is not even in the near future, but in the immediate future." We refer to these words because another opportunity is afforded us of emphatically supporting Mr. Gordon's contention. We cannot be accused of over sanguineness as to the success of companies. We do not profess to be masters in the art of City intrigue and mystery, but we can see that the very failure of company after company has been and will be one of the causes of the ultimate success of electricity. To discuss this would, however, lead us away from the immediate object of this article. The book is written by one who has had to study the problem of electric lighting from a practical standpoint, and thus it touches more or less fully upon parts of the subject that have hitherto been wanting in text books. A clear and concise chapter deals with the relation of electrical units to each other and to heat and work units. The worker should be as familiar with this and the following chapter on circuits as the schoolboy with his multiplication table; in fact, we have here the fundamental formulæ required for almost all ordinary electric light calculations. Not only are the formulæ given, but also examples fully worked out. Unfortunately, though Congresses meet, discuss and define units, the multitude continues for some time in the old ways, and so we get confusion. Thus H.P. English is not the same as H.P French, and the reader has to remember two constants when one should suffice. The latter part of the chapter on circuits treats of the H.P. wasted in a system of street-mains, and formed the subject of a paper before the Society of Telegraph Engineers on December 13th, 1883. A description is given of the instruments required in obtaining measurements in electric light operations, such as Siemens' dynamometer, Thomson's reflecting galvanometer, graded galvanometer, &c., Ayrton and Perry's ammeter, and other instruments. The various incandescent lamps, their peculiarities, and the details of their manufacture are discussed in Chapter VI., while the next chapter deals with

Digitized by Google

certain forms of arc lamps. Among the arc lamps the newest form of the "Crompton and Crabb," called the D D or double differential lamp, is described as follows:—

"The latest type of lamp* made by Messrs. Crompton and Co. is known as the D D (double differential) lamp. It also is the joint invention of Messrs. Crompton and Crabb, and shows a marked improvement on the older forms in point of simplicity of construction and also in regulation. This latter is effected by a brake wheel driven by the rack rod attached to the upper

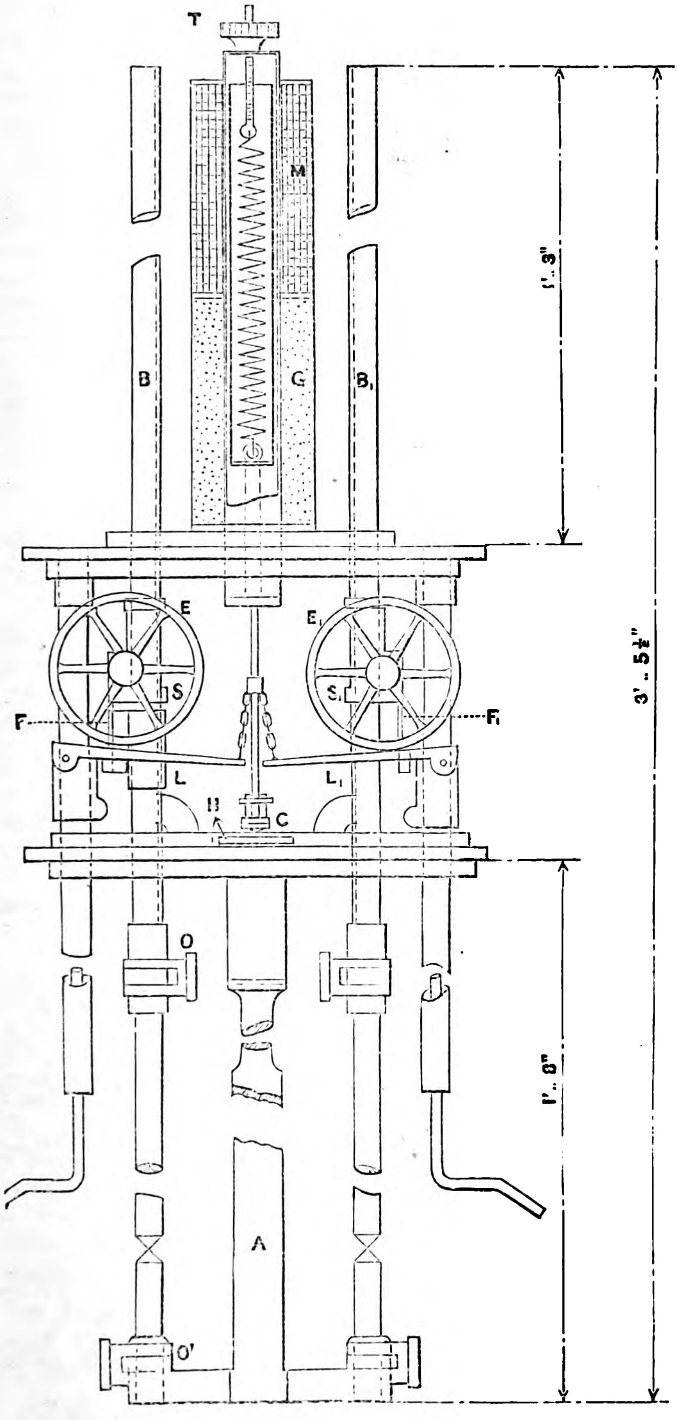

PLATE XII.—Crompton's D D Lamps.

carbons, as in the 1881 pattern, over which, however, the D D, in common with the K lamp, possesses the great advantage of being able either to increase or decrease the length of arc as may be necessary, whereas the older lamp could only decrease it. In the D D lamp also the intermediate gearing between the brake-wheel and the pinion driven by the rack rod is dispensed with. Referring to Plate XII., B and B_1 are the rack rods carrying the positive carbons. Sliding on each of these is a light gun-metal sleeve, S S_1, carrying spindles, to which are attached the two large brake-wheels E E_1, and between them the pinion which gears into the racks. To each side rod is pivoted a broad lever, L L, at the other end of which a chain is fastened, connecting it to the hollow core of the solenoid vertically above. This solenoid is differential, as in the K lamp, G being the shunt and M the main coil, and has its core partially supported by a spring, whose tension can be regulated by means of the screw T. Projecting vertically downwards from each sleeve to a distance from the centre of the spindle about equal to the radius of the brake wheels is a stout pin or finger, F F_1, the use of which we will try to make clear. Suppose the rack rod to be drawn up, then, if the lever be pulled by the solenoid above the horizontal position, the whole weight of the rod and carbon is supported on the edges of the two brake-wheels, and the friction of them on the surface of the levers is sufficient to prevent their revolution; hence this rack rod cannot run down. But if the levers be below the horizontal, then the weight is carried by the finger projecting from the

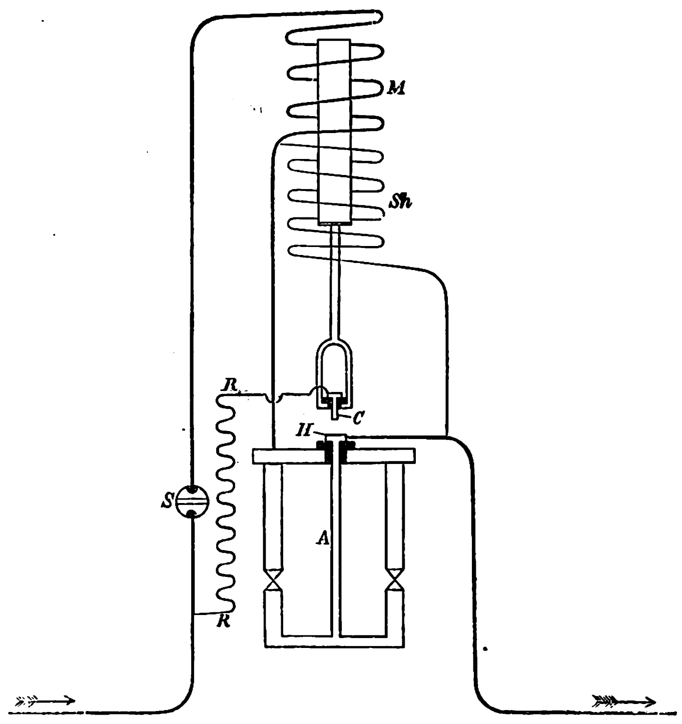

FIG. 49.

sleeve, as shown at F, the wheels are free to turn, the rack runs down, and continues to do so until the positive and negative carbon points come in contact. Now let the current be switched on by its passage through the main wire of the solenoid, the levers are raised, striking the arc, and at the same time applying the brake to the wheels. The shunt current then flows, and the arc takes its proper length. If this becomes too great, the increased current through the shunt draws down the core and levers, the brake-wheels are left free to revolve if the arc shortens. On the other hand, if the carbon points be too close, the levers are raised, bringing with them the rack rod and upper carbons. Making the finger projecting from one sleeve longer than that from the other determines which pair of carbons shall begin to burn first, because, on switching on, that pair which has the longer pin will be the last to break contact, and will therefore originate an arc in so doing. It will be easily seen from Plate XII. that on the core being raised the lever L_1 will apply the brake before the lever L does, hence it may be said that the rack rod B_1 gets a start on B; its carbon points are separated before those of B, and are kept a greater distance apart until the latter are consumed. When this is the case the rack rod B_1

* We are indebted to Messrs. Sampson Low and Co. for the illustrations to this notice.—Ed. *E.*

Digitized by Google

is prevented from further fall by a stop, and can no longer feed; hence the arc will lengthen, the shunt current will increase, and the other rod B_1, which can still feed, will be allowed to descend until its carbons touch, starting a fresh arc. The core is raised again, the fresh arc burning instead of the old one, and everything goes on as before. When the second pair of carbons has burned low, the same action takes place, viz., further descent of the rod is prevented, the arc lengthens, the shunt current increases, and the core is drawn down, but lower than when the first pair of carbons were burned out, until a copper stud, C, attached to it makes contact with another, H, connected to the negative pole, cutting the lamps out of the circuit, and introducing an equivalent resistance. Connections of the lamp and its equivalent resistance coil are shown in Fig. 49, page 33. The current entering in the direction of the arrow finds two paths open, the one through the resistance coil R R and insulated contact piece C, which for the time being is resting upon H, and thus on to the next lamp; and the other through the switch S, which we suppose to be closed, the main solenoid, coils M, the framework of the lamp, the positive carbon, the negative carbon, and ultimately out by H, and on to the next lamp. The latter portion of the current in passing round the core magnetises it, and draws it up, thereby breaking contact between C and H. In this moment the current has only one path open, viz., that through the switch S, main solenoid, and carbons; and since the whole of it must pass through the main solenoid, the core of the latter is definitely drawn up, lifting the two rack rods, and establishing the arc between one pair of carbons, as explained above. If, through the falling out or breaking of a carbon or hanging up of the rack rods the current should be interrupted, then the core of the solenoid will instantly fall, and, by bringing C and H again into contact, open to the current the former path through the resistance coil. In this manner an accident to one lamp does not affect the other lamps burning in series with it on the same circuit. The same result will follow if the current be interrupted through the opening of switch S, and the lamp thereby be switched out of circuit. When fitted with the full length of 19½in. of carbon 13mm. in diameter, the lamps will burn from twelve to sixteen hours, according to the current passing, which may vary from 6 to 28 amperes, the light varying from 850 to 6,500 candles, the candle-power being measured at an angle of 30deg. below the horizontal line, cutting the arc itself. The electromotive force required is 50 to 60 volts."

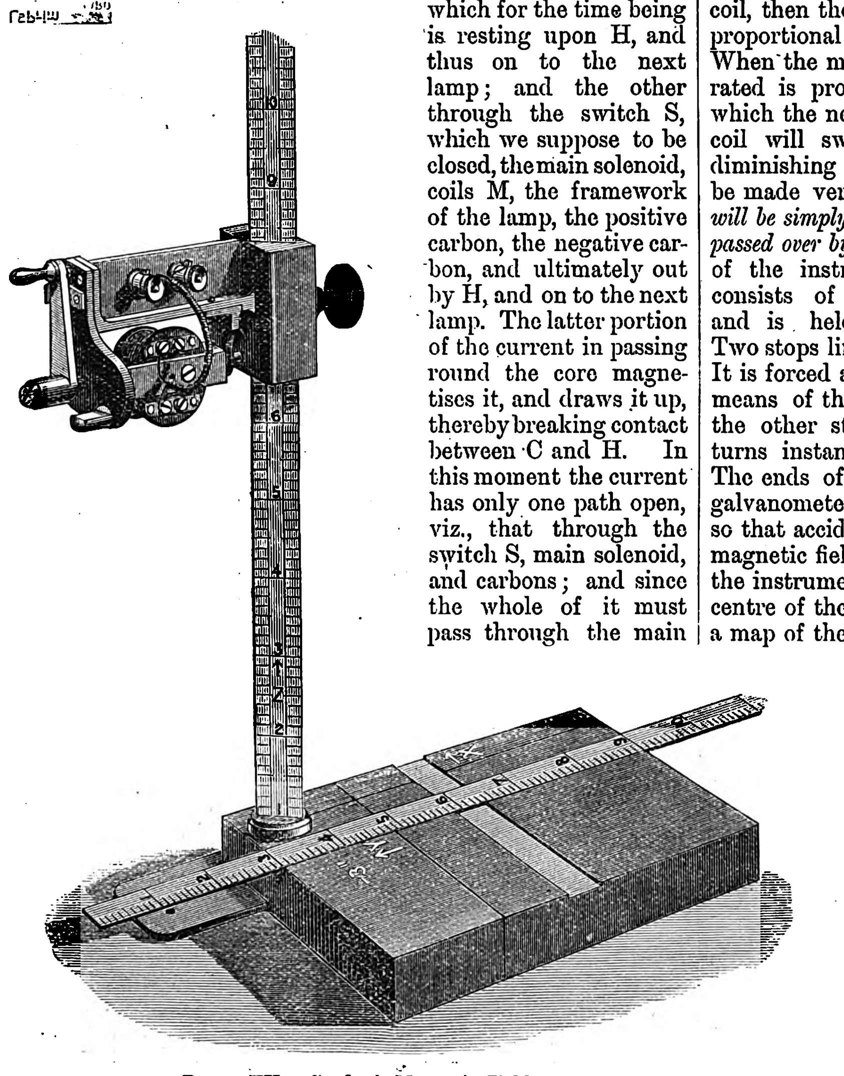

Plate XV.—Gordon's Magnetic Field Measurer.

Completing this portion of the work is a chapter on "Carbons for Arc Lamps," for which the author credits Mr. Crompton.

The latter half of the book is devoted to the consideration of machines for the generation of the electric current, and an appendix containing a number of useful tables. In the early portion of this part is discussed the theory of the generators, and among other interesting information is the description of an instrument designed by the author to measure the intensity of a magnetic field. This instrument has been described to the Society of Telegraph Engineers :—

"The principle on which the apparatus works is that if a small coil of wire, placed in a magnetic field, moves rapidly for a quarter-turn round an axis at right angles to the axis of the coil, then the total quantity of electricity generated is simply proportional to the strength of the magnetic field at the coil. When the motion is rapid, the quantity of electricity generated is proportional to the sine of half the angle through which the needle of a galvanometer connected to the moving coil will swing. By using a reflecting galvanometer and diminishing its sensibility by shunts, the angle of swing can be made very small, and then *the strength of the magnetic field will be simply proportional to the number of divisions of the scale passed over by the first swing of the light spot.* The practical form of the instrument is shown in Plate XV. The little coil consists of an ebonite bobbin wound with fine wire, and is held in a light brass frame pivoted on an axis. Two stops limit its motion, so that it can turn through 90°. It is forced against one of the stops by means of a spring. By means of the handle it can be turned till it is forced against the other stop. On the handle being released, the bobbin turns instantly through 90° under the action of the spring. The ends of the bobbin are connected to the poles of the galvanometer by means of two thin wires twisted together, so that accidental motions of the connecting wire through the magnetic field may not affect the galvanometer. The stand of the instrument is so graduated that the exact position of the centre of the bobbin in the magnetic field can be noted, and so a map of the latter can be constructed with the intensity at each point. Lines are engraved on the base from which the horizontal distances in two directions (at right angles to each other) from the centre of the magnet can be measured by the rule shown lying on at the base, and divisions in the vertical stem give the height above the face of the magnet. A gauge enables the bobbin to be set vertically over any point on the surface of the pole plate. With magnets such as are used in my alternating-current machines, the centre of the face of the pole plate is taken as 'origin,' distances measured along the circumference of the magnet-wheel are called x, those along the radius are called y, and those perpendicular to the face are called z.

"Thus such a memorandum as

$$x = 3'', y = 0, z = 4'', d = 270, c = 24 \text{ amps.},$$

would mean that at a point on the circumferential line 3 inches to one side of the centre of the magnet and 4 inches from its swing the magnetic field was such as to cause the light-spot to face over 270 divisions of the scale when the magnetising current was 24 amperes."

We remember that frequently during recent years novelists, playwriters, and professors of legerdemain have condescended to tell us "that's how it's done," and it has been left for Mr. Gordon to follow the same lines with regard to dynamo machines. He tells us that mathematicians as mathematicians are feeble folk, and unless they are mechanicians as well little will result from them of a practical character. "The mathematician working on paper is at liberty to assume conditions which cannot be satisfied in practice. . . ." The author suggests that "practical engineers should acquire for themselves such mathematical knowledge as they require. Then their mathematics will again and again assist them in their designs, and

Digitized by Google

their practical experience will tell them when symbolic reasoning has led them to an absurd result." We agree with the author to some extent. He refers to the design of an eminent mathematician as an example to the point. We should prefer to think that the failure of hundreds of machines is due rather to the lack of working drawings than to the lack of mechanical or mathematical skill. There is too great a hurry to patent the "idea." Plans are not committed to paper, but generalities and may-be's are—that is, the inventor proposes to do this and that by this or that or a variety of ways, not one of which has formed the subject of a working drawing. The author sees the necessity of a constant appeal to drawings, as will be gathered from his remarks on page 145. It will be interesting to many to read Mr. Gordon's views regarding alternate current machines, regarding machines of a high and of a low velocity, thus getting the reasons which induced him to design his own machine.

Besides the alternate, several typical direct-current machines, such as the Bürgin, Brush, and Edison machines, are described. Mr. Gordon is very hard upon secondary batteries, contending that the only storage worthy the name "is a spare boiler full of steam, with a banked fire, and a spare engine and dynamo, kept warm, well oiled, and ready to start at a moment's notice." We beg leave to doubt the conclusions of Mr. Gordon as to the value of "secondary batteries." This is not the place to enter into a discussion, but from what we have heard of the working of the Great Western Brush Company—a company which, by the by, has been silently working and endeavouring by a rigid economy and attention to business to counteract the effects of wild speculation—secondary batteries have proved of great use. In the winter a duplicate plant is always ready; with the long days part of the plant is unused, secondary batteries forming a stand-by or a source of current before or after the engine is stopped. One more word. No difficulties have been met with in the use of such batteries, which are of the Faure-Sellon-Volckmar type. If what we have stated is correct, the facts are too strong for any business man to ignore.

The contents of Mr. Gordon's book have been thus briefly indicated. It contains many statements open to criticism, but without doubt it is the most valuable work on electric lighting that has yet appeared. It is essentially non-mathematical, readable, and practical. A word of praise is due to the publishers for the excellent manner in which the book is illustrated and produced.

Electricity: its Theory, Sources, and Appliances. By John T. Sprague, M.S.T.E.&E. Second Edition, greatly enlarged. [London: E. and F. N. Spon, 16, Charing-cross.]

The new edition of this book reaches us just as we are going to press, but as many correspondents have at various times asked for information as to its publication, we notify that it is now ready, and reserve any remarks we may have to make till after reading the work.

A Pocket Book of Electrical Rules and Tables for the Use of Electricians and Engineers. By John Munro, C.E., and Andrew Jamieson, A.M.I.C.E., F.R.S.E. [London: Charles Griffin and Co., 12, Exeter-street, Strand.]

Although this book has been in our hands but a few hours —far too few, indeed, to adequately investigate its contents— yet a cursory examination is such that it seems an imperative duty to call attention at once to its publication, and to induce every reader to obtain a copy. The plan has evidently been to produce an electrical "Molesworth," and, so far as we can judge, with great success; in fact, for a first edition it seems wonderfully perfect. No doubt the compilers will at once commence to note suggested alterations, new information, and so on for future improvement. Some errors will doubtless be found, but, except in the definitions, we have as yet failed to find any. We are not quite sure whether many of the tables had not better be relegated to the rubbish heap. It may be that we have somewhat sinned in publishing "tables" having but a tentative value, but we contend that a difference exists in the publishing of tables in a periodical and in a pocket book. The compilers, for example, might well consider the real value of the table on pp. 214, *et. seq.* Is it, in fact, of any practical value whatsoever? The answer to such a question may perhaps be given by an appeal to the writings of Forbes, Gordon, Blakesley, and others. However, we shall leave criticism for the future, satisfying ourselves that the pocket book as presented now is worthy of all the commendation we can give it.

ON THE PHYSICAL PROPERTIES OF METALS.*

BY SHELFORD BIDWELL, M.A., LL.B.

Having observed that the coefficient of the Thomson effect is generally positive in those metals which have a great specific resistance and specific heat, and negative in those which are distinguished by a great coefficient of expansion, the author endeavoured to find an empirical formula, expressing the coefficient of the Thomson effect in terms of the specific resistance, specific heat, and coefficient of expansion. Though he was not altogether successful, he believes that the subjoined table points to the existence of a close relation between them.

I. Metals.	II. Coefficient of Thomson Effect.	III. $H \times R - E^2$	IV. Last Column Divided by 2,400.
Ni	5·12	12,320	5·13
Fe	4·87	9,918	4·13
Pd	3·59	7,086	2·95
Pt (soft)	1·10	2,309	0·96
„ (hard)	0·75		
Mg	0·95	1,384	0·58
Pb	0	– 604	– 0·25
Al	– 0·39	1,942	0·81
Sn	– 0·55	– 868	– 0·36
Cu	– 0·95	– 1,137	– 0·47
Au	– 1·02	– 1,172	– 0·49
Ag	– 1·50	– 2,246	– 0·94
Zn	– 2·40	– 2,355	– 0·98
Cd	– 4·29	– 4,958	– 2·07

The first column contains the names of all the metals, except alloys given in Tait's thermo-electric diagram (*Transactions* R. S. E., Vol. XXVII., p. 125). The second column gives the coefficients of the Thomson effect. These are taken from Everett's table ("Units and Physical Constants," p. 151), which is based upon Tait's diagram.

H R and E being numbers proportional to the specific heats, specific resistances, and coefficients of expansion of the various metals, $H \times R - E^2$ gives the numbers in the third column. H = spec. heat $\times 10^3$, R = spec. res. $\times 10^3$, E = expansion $\times 10^8 \div 34$. The multipliers 10^3 and 10^8 were used merely for the convenience of getting rid of decimals; the division 34 was so chosen that while the ratio of the first number to the last in column III. should be as nearly as possible equal to the ratio of the first number to the last in column II., the number corresponding to lead in column III. should at the same time be as near zero as possible. Both conditions could not be exactly fulfilled at once.

Column IV. gives the numbers in column III. divided by 2,400, to facilitate comparison with column II.

It will be seen that with one exception the order of magnitude of the numbers in column IV. is exactly the same as the order of those in column II. The rate of decrease is not, however, the same, the numbers diminishing too rapidly in the upper half of column IV., and too slowly in the lower half.†

* Abstract of a paper read before the Royal Society, May 7th.

† With regard to aluminium it is suggested that Matthissen's determination of the specific resistance 0·029 is possibly too high. Moreover, the author found experimentally that the Thomson coefficient of the specimen of aluminium which he used was slightly + instead of – as given in column II. It is also shown as + in the diagram at p. 178 of Jenkin's "Electricity." If its specific resistance were as high as 0·026, it would come between magnesium and lead in column IV.

THE SUBMARINE CABLE CONVENTION.

Small concessions are always more certainly obtainable by large demands than by diffidence or moderation. The provisions embodied in the Convention for the Protection of Submarine Cables, published in our last issue, are a case in point. The proprietors of these cables put forward claims which we stated at the time would never be acceded to, and which, indeed, were probably never expected to be listened to. Nevertheless, there being a good substantial case to go upon, and the applicants being powerful enough to get a hearing, valuable concessions have been made to them; and if all has not been obtained that was asked for, as much has been given as could be reasonably expected. The moral offence of injuring or destroying submarine cable property has been declared a legal offence, and proprietary rights in respect of this class of property has been fully recognised by the leading civilised nations of the world.

The cable companies will probably not regard the decisions of the International Convention of Paris as final, and no doubt something more is not only needed but will be granted at a not far distant date. But for the present it is a great achievement to have established the principles—first, of legal ownership; and secondly, of international protection. The circumstance of plenipotentiaries representing more than twenty nations of Europe, Asia and America meeting together to impose legal obligations upon each other is sufficient evidence of the latter, whilst the former is shown in the wording of the second clause of the Convention. Article II. declares that "It is a punishable offence to break or injure a submarine cable wilfully or by culpable negligence." It will be news to some people that the offence here referred to is created a punishable one now for the first time. It is one that has been committed on many occasions; sometimes, as is gravely suspected, with malicious intention, often with culpable negligence, always with confidence in immunity from punishment. We may confidently predict that motives of prudence will henceforward assist the moral sense, and so diminish the number of preventible injuries.

Besides the punishment of such offences, in a manner to be hereafter determined by the respective countries, actions for damages will be sustainable under the provisions of this Convention. Hitherto it has been difficult and perhaps impossible to bring an action for damages done to cables beyond territorial waters; and consequently the very first Article declares that the convention shall apply outside territorial waters—that is to say, to those waters outside the shore boundaries over which each country already possesses some jurisdiction. Indeed, if we understand Article I. aright, the Convention applies only to the high seas, and assumes that the municipal law of each country is competent to take care of the region included in the shore boundaries. What was needed was a territorial standpoint for places beyond the reach of municipal law; and this is provided by Article VIII., which identifies the offence with the country of the offending vessel:—"The tribunals competent to take cognisance of infractions of this Convention are those of the country to which the vessel on board of which the offence was committed belongs." Nor is the prosecution to be left to the injured parties, for Article IX. stipulates that such offenders shall be proceeded against by the State or in its name, independently of any action which cable proprietors may institute for damages on their own account. The nationality of the offending vessel is generally ascertainable; but when a ship of war is in the vicinity its officers are authorised to "demand from the captain or master the production of the official documents proving the nationality of the said vessel." Lastly the high contracting powers have engaged to take or propose to their respective legislatures the necessary measures for summarily punishing by either fine or imprisonment, or both, those who contravene the provisions of the Convention. There should be little difficulty in passing the requisite Act of Parliament to meet this engagement.

No exception will, we imagine, be taken to the conditions imposed on the other hand upon the companies themselves. In laying cables they are to be compelled to place them in positions of safety, and to construct them of proper dimensions. During the operations of cable laying, buoying, or repairing they must give due notice to fishing craft, who on their part, after due notice, must keep at safe distances from the scene of operations. Rules as regards signalling which are now in use receive an international recognition under the

Digitized by Google

Convention, and responsibility for disregarding them, or negligently not seeing them, is thrown upon the vessel doing damage in consequence. A judicious provision enables vessels that have abandoned their anchor or tackle to avoid injuring a submarine cable to claim compensation from the owners of the cable—a provision which will greatly reduce the damage done by fishing boats on the too-often-alleged plea that to respect other people's property would have endangered their own.

On Article XV. there appears to have been some slight fear of misapprehension. It reads thus:—"It is understood that the stipulations of the present Convention do not in any way restrict the freedom of action of belligerents." It was chiefly on this point that full consideration was demanded by some of our cable proprietors. Oddly enough, it is the plenipotentiary representing this country who emphasizes the understanding in a supplementary note to this effect:—"Her Majesty's Government takes Article XV. to mean that in time of war a belligerent will be free to act . . . . as if the Convention did not exist." Nothing less was understood, we should imagine, by any of the contracting parties; for an engagement to respect cable property in time of war would certainly be broken as soon as war commenced, and no nation can afford to have its hands tied in regard to other nations' property when its own would inevitably be destroyed. Submarine cables, however, in this relation are not rightly described as property, but as aids of warfare, like ships, tunnels, land telegraphs, and railroads. The general provisions of the Convention are so beneficial for times of peace that there is no room to regret that an illusory protection was not accorded to submarine cables in time of war.

CORRESPONDENCE.

ZINC-LEAD ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

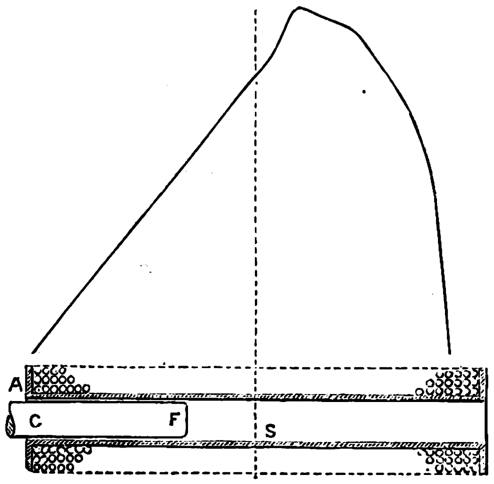
Sir: In *The Electrician* of February 9th is an interesting account of a zinc-lead accumulator. In your last edition we have some comparative results obtained with this combination, which is not new. Those not acquainted with the action of secondary batteries would very naturally conclude from these results that zinc—the king of primary batteries—would hold the same position in respect to secondary ones. Theoretically this is very nice—practically it is useless. If we take for experiment an accumulator of any of the known types, and substitute zinc plates for the existing lead ones, or what is more simple, make the electrolyte a saturated solution of zinc sulphate by charging the cell in the usual manner, we cover the negatives electrolytically with zinc. By taking out the now very acid solution, and refilling the cell with zinc sulphate as before, we then have a zinc-lead accumulator. On the second charging of this arrangement an alteration takes place. We deposit some of the zinc from the electrolyte, which has the effect of leaving it very acid, which acid has a great liking for the rough deposit of metallic zinc. This it greedily devours, liberating a quantity of hydrogen, which we know is not beneficial to the opposite pole. If we discharge the cell immediately after the charging is complete (it is difficult to tell where such is the case without an acidometer, while zinc remains in solution there is no gas disengaged), we get a powerful discharge of fully 2·35 volts, and if we rapidly discharge the cell we get a return of 97 per cent. If we let the cell rest a few days or a week the results are not so pleasing. If we fully charge a set of zinc-lead couples to-day for use to-morrow, during the night the cells will be very active. The electrolyte having given up the greater part of its zinc will contain much free acid, which acid will speedily regain its share of zinc, giving off a great quantity of hydrogen, much to the satisfaction of the peroxide of the negative element, and much to the dissatisfaction and danger of those compelled to be with or near them. The deposit of metallic zinc is very pelverulent, which necessitates a great distance between the plates to prevent contacts. There is an accumulation of dirty crystals of zinc sulphate, which does not improve the mind in the direction of trouble and economy. The use of cupric sulphate in connection with copper plates (Sutton's arrangement) is open to similar defects in a lesser degree. If we discard lead as a negative pole we are going in the wrong direction, for this pole has never been any trouble, but is simply perfection.—Yours, &c.,

H. A. Kent.

SOLENOIDAL ACTION.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Having recently made some experiments on the pull exerted by a solenoid on an iron core, we met with certain results which may perhaps be unknown to some of your readers, and we therefore venture to send a few particulars. Referring to the diagram, S is the solenoid, and C the iron core. Suppose the end F of the core to be inserted into the solenoid at A, and gradually moved through the coil. The curve shows the pull at any corresponding position of the end F. It will be noticed that the curve follows the "straight line law" until F reaches the centre of the coil; a slight dip then occurs, but the point of maximum pull is reached when the *magnetic pole of the cone is at the centre of the coil;* another



dip then occurs, and the curve gradually drops to zero. The first dip is evidently caused by the back pull of the coil on the part of the core between the end and the magnetic pole. The experiments were made with reference to our electric meter, and we devised a simple apparatus to automatically draw the curves.—Yours, &c.,

Gilbert Hammersley,
C. H. Worsey.

Birmingham, May 19, 1882.

ELECTRICAL UNITS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Is there any way of expressing these, all to one scale as it were, so as to convey some definite idea of their meaning and comparative powers? for it is hard to realise the actual effects of either the theoretical or the practical units as given in the text books. Do they not each signify either an effort or an obstacle? and if so, cannot the equivalent of each be stated in foot-pounds?

It is hardly fair to ask you to correct sums, but can you kindly explain how the formula ($C = \cdot 362\, D \tan \delta$) is derived from $C = H \tan \delta . \frac{a}{2\pi}$? (Gordon's "New Treatise on Electric Lighting," pages 40 and 41).

I make it ($C = \cdot 036\, D \tan \delta$) as enclosed; and similarly, his example on page 41 comes out ·304 instead of 3·04.—Yours, &c.,

Country Student.

ARTIFICIAL LIGHT TABLES.—(Copyright.)

(Showing the time during which Artificial Light is required throughout the year).

BY A. P. TROTTER, B.A., A.M.I.C.E.

Table I.

The shaded area represents the time during which artificial light is required throughout the year. The horizontal lines divide the diagram into twelve months, and the vertical lines show the hours of the day and night, from 2 p.m. to 9 a.m. The inner dotted lines show the time of sunset and sunrise.

In order to ascertain the approximate time of dusk, a number of circulars were sent out to the large houses of business and to establishments where electric light has been in use for some time, asking if any record had been kept of the time of lighting up, and for information as to the frequency and duration of fogs.

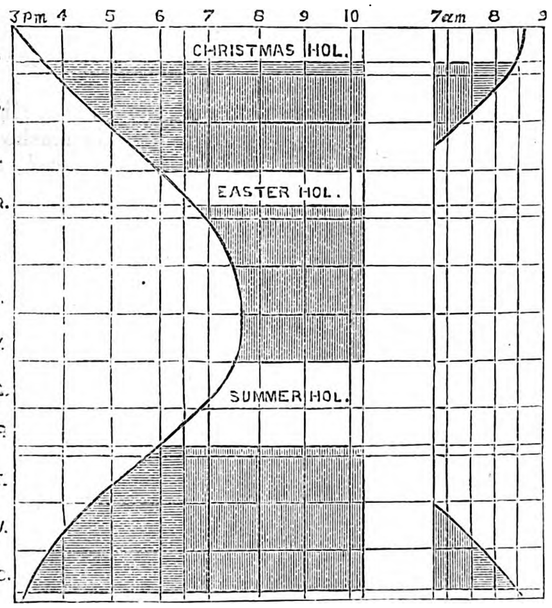

TABLE I.

The only useful answer was from the South Kensington Museum, and this was as complete as it could be. The curved lines on the diagram are laid down from an average of the daily record of the time of lighting up for the last three years. When light has been used all day on account of fog, &c., this has been taken into account and spread in the proper proportion over the foggy part of each year. The curves for the three years were taken separately, and agreed fairly well with each other, and the average was taken by interpolation. It may be noticed that November does not appear to be guilty of its proverbial amount of fog.

The time of dusk will of course be later for outdoor lighting than for indoors, and earlier for town than for country.

It may be ascertained from the diagram that if an establishment closes at half-past seven all the year round the amount of time during which light will be needed is measured by about 26 squares. Each square is an hour-month of 30·4 hours, or if Sundays and the six holidays be omitted, 25·6 hours. The time required will therefore be about 660 hours. If the time of closing be an hour later, 365 or 307 hours must be added.

The table was originally suggested in the course of reckoning the amount of light required for a large public school, the average duration of the holidays being struck out. The diagram shows at a glance, in this case, the proportion of light used in the school buildings and in the masters' houses when transferred to the latter after school hours. The time of dusk has been put back a little, being for the country.

Table II.

The shaded area represents the time during which light is required.

The horizontal lines show the months of the year.

The vertical lines show the hours of the day and night.

The inner dotted lines show the time of sunset and sunrise.

The outer lines show the time of lighting up and extinguishing.

Each square is an hour-month, *i.e.*, 30·4 hours, or if Sundays and the six holidays be omitted 25·6 hours.

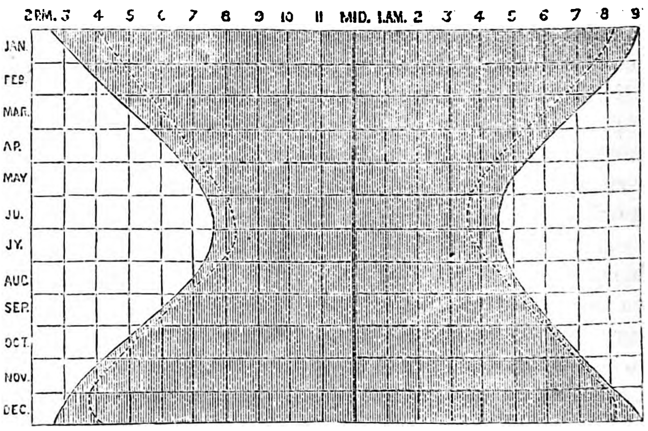

TABLE II.

If light is required from dusk till 7:30 all the year round, the total time will be about 790 hours. If Sundays and the six holidays be omitted, the total will be about 660 hours.

For every hour later add 365 or 307 hours.

ON THE FIELD MAGNETS OF DYNAMO MACHINES.

In a recent communication to the Vienna Society of Electricians Dr. A. von Waltenhofen attempted a scientific justification of F. Uppenborn's purely empirical rule for the exciting power necessary to properly magnetise the field magnets of a dynamo machine. According to this rule * the exciting power should be proportional to the cross-sectional area of the field-magnet cores, the proportion being 110 ampere turns for every square centimetre of core area. In English measure this gives about 700 ampere turns per square inch. Without pronouncing any opinion on the practical value of this rule, which gives exciting powers by far in excess of our best modern English practice, we nevertheless think a short abstract of Von Waltenhofen's reasoning will be of interest to our readers, the more so as this subject has up to the present not received sufficient attention, and trustworthy rules for the design of field magnets are nowhere to be found.

The author puts two propositions :—

I. We can either excite the field-magnets to a certain point of magnetic saturation, thereby making the total magnetism proportional to the total weight of the field-magnets, or

II. We can excite to such a degree that the free magnetism appearing chiefly on or near the polar surfaces is proportional to the total weight of the field magnets.

Ad. 1. According to Mueller and Dub, the total and the free magnetism of cylindrical cores of equal length but different diameter excited by the same number of turns carrying the same current is proportional to the square root of the diameter.

* J. Uppenborn, "Kalender für Elektrotechniker," p. 123.

Digitized by Google

If length and diameter vary, but in such a way that the ratio of diameter to length remains constant, we know by Sir W. Thomson's rule that similar cores similarly wound with the same size wire, the length of which is in each case proportional to the square of the linear dimensions of the core, and traversed by the same current, produce in points similarly situated equal magnetic forces.

From this law and from that giving the action of a magnet at a distance it follows that the magnetic moment of similar cores is proportional to the cube of their linear dimensions. By combination of this with the above thereom of Dub we find that the magnetic moments of cores of different lengths magnetised by an exciting power in proportion to their lengths are as the $\frac{5}{2}$ power of the length, and if magnetised by the same exciting power they are as the $\frac{3}{2}$ power of the length.

Let x be the exciting power, y the corresponding magnetic moment, l the length, d the diameter, and k a constant, then is

$$y = x.\, k \sqrt{l^3 d}\,.$$

Let y_1 be the magnetic moment for maximum saturation, and $\mu = \frac{y}{y_1}$ a coefficient denoting the degree of saturation which is produced by the exciting power x, then is

$$\mu = \frac{x\mathrm{K}.\sqrt{l^3 d}}{y_1}.$$

Now, the maximum of magnetic moment corresponding to complete saturation was shown by the author to depend only on the volume of the core,* so that y_1 is proportional to $l\,d^2$, and therefore

$$\mu = \frac{x\,\mathrm{K}}{d}\sqrt{\frac{l}{d}}.$$

For field magnets of different size but geometrically similar proportions $\sqrt{\frac{l}{d}}$ is a constant, and since K is also a constant it follows that to obtain equal degrees of magnetic saturation in field magnets of different size, the exciting power must be proportional to the diameter of the core.

Ad. II. It is therefore evident that Uppenborn's rule cannot be deduced from the condition of equal saturation. The other condition was that the free magnetism at or near the polar surfaces should be proportional to the weight of the field magnets. Dub has shown that for equal magnetising powers the free magnetism at the ends of cylindrical cores is proportional to the square root of the length; since it is also proportional to the square root of the diameter we obtain for the free magnetism

$$\mathrm{F} + x\,a\,\sqrt{l\,d},$$

x being the exciting power and a a constant. By the condition Sub. II. the proportion between free magnetism and weight of field magnets, that is, between F and $l\,d^2$, is to be constant; hence we find that $\frac{x\,a}{\sqrt{l\,d^3}}$ must be the same for different sizes of geometrically similar field magnets, a condition which can only be fulfilled if

$$x = \mathrm{A}\,d^2$$

where A is a constant coefficient.

This is, in fact, Uppenborn's rule, by which the exciting power is made proportional to the area of the core—that is, proportional to the square of its diameter.

The author concludes by saying that the above only applies to the field-magnets after the armature has been removed. With the armature in place the conditions are somewhat modified.

THE DIAMETER OF CONDUCTORS TO PREVENT OVERHEATING IN ELECTRIC CURRENTS.*

BY PROFESSOR GEORGE FORBES.

(CONTINUED FROM PAGE 18.)

In computing with this formula, it must be noticed that the value of R, the specific resistance, varies with the temparature. The resistance at 0° C. is 1642. At the temperature of the air (which may be taken at 20° C.) it is 1736), and at any temperature which is $t°$ above 20° C. the resistance is 1642, *i.e.*, $1 + {\cdot}0038\,(t + 20)$. This change of resistance produces a change of 15 per cent. in the current which can be carried at the higher temperatures.

The effects of temperature in altering the resistance are continually cropping up in our application of theory to practice, and the following very striking experiment is worth recording:—

I have been informed by Mr. H. Edmunds that he made experiments with wires $\frac{1}{32}$ inch diameter, flattened out to various widths, through which he passed the current from a machine, the E.M.F. being the same in all the experiments. In the form of wire $\frac{1}{32}$ inch diameter, it was heated to a bright colour; when flattened $\frac{1}{16}$ and $\frac{1}{8}$ inch width it lost luminosity; and so on until, when used in a strip $\frac{1}{2}$ inch wide, it kept pretty cool, and fairly stopped the engine. Here we see that the resistance of the wire and all the strips was the same at any constant temperature, but the surface for cooling by radiation and convection was greater with the wider strips. This explains why the wider strips were cooler than the narrower ones, and still more than the wire. Lastly, the resistance is trebled at a temperature which makes the metal barely luminous, and is enormously increased at a bright heat. Hence, in the cases where there was bright luminosity, there was high resistance and less current. The wide strip, being the coolest, had most current, and used up most work, and so stopped the engine.

In the preceding table (as in others which follow it), the current specified heats the wire to the degree stated only when steadily applied. A much more powerful current might be used for a very short time at intervals, as in signalling for railways.

The only doubt of the accuracy of the calculations can come from a doubt as to the accuracy of M'Farlane's experiments, which were made in Sir William Thomson's laboratory, or in the extensions of his results to surfaces of different dimensions. On this matter I have a few remarks to make.

1. The value which M'Farlane found for the loss of heat per second per degree difference of temperature between the metal and the enclosure increased from $t = 5°$ C. to $t = 60°$ C. in the ratio 178 : 226 for polished copper. I have used the value 178 in calculating the above table, so that the current which can be carried with the copper in any state of oxidation or dirt is certain to lie between the two values given in the table under *bright* and *blackened*.

2. The only experiments with which I can compare Mr. M'Farlane's are those by the late Mr. Nichol, published by Professor Tait in the *Proceedings* Royal Society, Edinburgh, 1869-70, p. 207. Table A gives the comparison.

A comparison of the results of M'Farlane and Nichol shows that they agree generally as well as could possibly be expected, so far as the term which depends on the first power of the temperature in the expression

$$\text{loss of heat} = \mathrm{A}\,t + \mathrm{B}\,t^2 + \mathrm{C}\,t^3 + \cdots$$

is concerned, but that in the comparatively unimportant second term M'Farlane makes B negative, and Nichol makes it sometimes positive and sometimes negative. The general conclusion is that we can trust safely to the first term, but that we must not push the application to extremely high temperatures.

3. Both the above sets of experiments were made upon masses of metal some centimetres in diameter, and the conclusion seems warrantable that with such masses my formula is accurate. I state this now, because I have next to show that the law does not extend to small masses where convection

* Paper read before the Society of Telegraph Engineers and Electricians.

Digitized by Google

plays a more important part than radiation. My impression is that thin wires lose their heat chiefly by convection when free in the air, but larger masses chiefly by radiation.

I worked at the subject experimentally in 1881 and the following years. My results were published in the British Association *Reports* 1882; *Annales de l'Electricité*, 15th October, 1882; *The Electrician*, 1882, September, and 1883, February.

TABLE A.

Loss of heat (per sq. cm. per second per degree centigrade difference of temperature) from copper in air at atmospheric pressure in blackened enclosure at constant temperature 8° C. in Nichol's experiments, for various differences of temperature:—

12·5	—	·000198	12·5	—	·000364
15·0	·000193	—	19·3	—	·000331
15·3	—	·000182	20·0	·000289	—
20·0	·000201	—	30·0	·000306	—
21·6	—	·000175	33·6	—	·000320
30·0	·000212	—	40·0	·000319	—
32·5	—	·000173	42·2	—	·000322
40·0	·000220	—	50·0	·000326	—
42·5	—	·000173	53·2	—	·000328
50·0	·000225	—	60·0	·000328	—
55·8	—	·000177			
60·0	·000226	—			

My first object in those experiments was to test the correctness of the following considerations:—

When a current passes through a wire that is keeping up a constant temperature, the heat developed by the current over a given length is equal to that lost by radiation, convection, and conduction. It seemed right to suppose that at a fixed temperature this cooling varies as the surface, *i.e.*, as the diameter of the wire. The heat generated by the law of Joule varies as $C^2 R$ or $\frac{C^2}{D^2}$, where C = the current, R the resistance, and D the diameter of the wire.

Whence $$\frac{C^2}{D^2} = a\,D \text{ (}a\text{ being a constant),}$$

and $$C^2 = a\,D^{\frac{3}{2}}.$$

To verify the exactness of this law, I experimented on several wires of different diameters but the same conductivity. Each wire was thinly coated with beeswax, whose melting point was 58° C., the temperature of the room being 18° C. A current was passed through one of these wires, and resistances were slowly and gradually removed from the circuit, until the current heated the wire so as to melt the wax. The angle of deflection of the tangent galvanometer was then read off, to give the intensity of the current. The same operation was repeated on the other wires, and the following table gives the results obtained:—

D	C	$\frac{C}{D}$	$\frac{C}{D^{\frac{3}{2}}}$	$\frac{C}{D^2}$
Mm.				
0·58	0·984	1·696	2·229	2·924
1·22	2·304	1·888	1·709	1·548
1·58	3·026	1·915	1·523	1·212

If $C \propto D^{\frac{3}{2}}$, the quotient $\frac{C}{D^{\frac{3}{2}}}$ should be constant for all the wires. If, as some have supposed, $C \propto D^2$, the quotient $\frac{C}{D^2}$ should be constant. If, lastly, $\frac{C}{D}$ is more nearly constant, as is seen to be the case, the law is that the current varies more nearly as the diameter.

Within the last few days I have come across some tests which I had made in 1881, on five thicknesses of lead wire, to find the current required to fuse them. I found that this depended upon the length of the specimen. The reason is that the ends of the wire are clamped by cold metal, which absorbs the heat, and so a greater current is carried without fusion with short specimens than with long ones. I give the results for what they are worth.

Fusing Currents for Lead Wires.

Diameter.	Length.	Fusing Current.	Diameter.	Length.	Fusing Current.
Mm.	Metre.	Amperes.	Mm.	Metre.	Amperes.
0·55	0·025	0·78	1·28	0·300	9·5
0·78	0·025	0·937	1·28	0·150	12·37
0·94	0·025	1·125	1·28	0·075	12·75
1·03	0·025	8·2	1·28	0·050	13·5
1·03	0·225	6·0	1·28	0·025	16·87

These measurements were not made by myself, and I cannot vouch for any very great accuracy. One fact which we learn from them is, that in such experiments, with wires about 1 millimetre thick, the length in experiments of this nature should be not less than 30 centimetres, or, generally, the length should be 300 times the diameter. The effect of using short wires is especially shown with the thicker ones, the experiments on which show that a large quantity of heat is carried off by thermal conduction to the massive cooling terminals.

Taking the case of a long wire, let us see how far it gives us reason to believe in the applicability of the formulæ of this memoir to practical cases. A lead wire, 1·28 millimetre diameter and of considerable length, was heated to the temperature of fusion with a current of 9·5 amperes, and one of 1·03 millimetre diameter with a current of 6·0: let us find the theoretical current required.

By referring to Problem I., we see that the heat generated per second in one centimetre length of the substance

$$= C^2 \frac{R}{\pi\left(\frac{D}{2}\right)^2} \times \cdot 24$$

where C = current in amperes,
R = specific resistance in ohms,
D = diameter.

Now R* = 19,850 at 0° C. for lead in C.G.S. units.
= 44,751 at 327° in C.G.S. units,
= ·000044751 in ohms.

The melting temperature of lead being 327° C.†, or, say, 310° C. above the surrounding air,

$$\therefore \text{heat generated} = C^2 \frac{\cdot 000044751 \times 4}{\pi D^2} \times \cdot 24 = \cdot 0000570 \frac{C^2}{D^2} \times \cdot 24.$$

Referring to M'Farlane's experiment, I find that 60° C. excess of temperature gives a loss of heat per square centimetre per second = ·01356 gramme centigrade heat units with polished copper, and that the loss is nearly proportional to the temperature. This would give ·07006 for 310° C.

The surface of one centimetre length of the first wire is

$$\pi + \cdot 128 = \cdot 402,$$

and of the second it is

$$\pi \times \cdot 103 = \cdot 324;$$

and the loss of heat is in the first wire

$$\cdot 07 \times \cdot 402 = \cdot 02814,$$

in the second

$$\cdot 07 \times \cdot 324 = \cdot 02268,$$

* Jenkin: Cantor Lectures.

† Balfour Stewart: "Elementary Treatise on Heat," p. 88.

Digitized by Google

and this must equal the heat generated as given above, viz.—

$$= \cdot0000570 \times \cdot24\frac{C^2}{D^2}$$

$$= \cdot00001368\frac{C^2}{D^2}$$

$$= \cdot000848\ C^2 \text{ for the first wire,}$$

$$\text{and} = \cdot001290\ C^2 \text{ for the second wire;}$$

whence for the first wire

$$C^2 = \frac{\cdot02814}{\cdot000848}$$

and for the second

$$C^2 = \frac{0\cdot2268}{\cdot001290}$$

which gives us 5·8 and 4·2 amperes theoretically in place of 9·5 and 6·0 respectively, as found by experiment. This only shows that M'Farlane's constant does not apply to high temperatures, and that the loss of heat is then much greater than in direct proportion to the temperature.

The only extensive experiments on the subject, with which I am acquainted, have been made by Mr. W. H. Preece, and the results are about to be communicated to the Royal Society. He has been kind enough to show me his experimental results, in order that I might be able to bring before you a comparison with my own results.

He measured the current which was just sufficient to melt platinum wires of different sizes, and he also measured the current which is just sufficient to make wires luminous. The results obtained by Mr. Preece confirm my experiments, and show that with small wires the (current)^2 is more nearly proportional to (diameter)^2 than to the (diameter)^3

(TO BE CONTINUED.)

TELPHERAGE.*

BY PROF. FLEEMING JENKIN, LL.D., F.R.S.

In the first place, it is necessary that I should define what is meant by this word "telpherage," and perhaps that I should defend its formation. The word is intended to designate all modes of transport effected automatically with the aid of electricity. According to strict rules of derivation, the word would be "telephorage;" but in order to avoid comparison with "telephone," and to get rid of the double accent in one word, which is disagreeable to my ear, I have ventured to give the former such a form as it might have received after a few centuries of usage by English tongues, and to substitute the English sounding "telpher" for "telephore."

In the most general sense telpher lines include such lines as were first proposed by my colleagues, Messrs. Ayrton and Perry. The word would also describe lines such as I have seen proposed in the newspapers for the conveyance of small parcels at extremely rapid rates. But to-night I shall confine myself entirely to the one specific form in which the telpher line first presented itself to my mind, and which it has fallen to my lot to develop. In this form telpher lines are adapted for the conveyance of minerals and other goods at a slow pace and at a cheap rate.

The problem which occurred to me was this: Was it not really possible to send vehicles, by means of electricity, along a single suspended wire or rod—in fact, to telegraph goods and passengers instead of messages? The idea is familiar as a joke, but on consideration it appeared that there must be good grounds for supposing that the idea was both practicable and useful. I am now able to show you the realisation of that idea, and the result of experiments on a large and practical scale has, I think, justified the arguments which induced me to devote much time and labour to telpherage.

[Here the model was shown in action. This model consisted of two concentric octagons of wire, the length of each outer span being 5ft. On each octagon there was a single locomotive and train, equal in length to that of the span. These trains ran well and steadily in opposite directions round the lines.]

These arguments may be stated as follows:—

We could not with steam employ a vast number of little one-horse engines to pull along a number of small trains or single waggons. There would be waste both in the production of power and great cost in the wages of the men employed at each engine. But an electric current of, let us say, 50 horse-power will, as it circulates through a conductor of moderate size, drive thirty small engines each of one horse-power, which require practically no supervision, and which can be made nearly as economical in their action as a single electro-motor of 30 horse-power could be.

But if the power can be distributed economically along a line, say ten miles in length, this allows us to employ thirty small trains, corresponding each to a waggon pulled by one horse, instead of a single train such as might require 30 horse-power. If we further distribute the weight by making each train of considerable length, we are able to employ an extremely light form of road, such as a suspended rope or rod of, say, ¾in. diameter. At a later period in the lecture I will show the amount of traffic which such a rod can practically convey. Meanwhile, I simply draw your attention to the general principles of the subdivision of power and the subdivision of weights. In distributing the power by means of electricity it was clear that considerable waste must be incurred, but the amount of that waste is easily calculated, and is by no means prohibitory. Moreover, the power, being obtained from stationary engines, or in certain cases from falls of water, could be produced at a cheap rate in comparison with that obtained from locomotives or traction engines.

When I examined the various forms of possible road by which the distributed power and distributed load could be conveyed it seemed to me that the single suspended rope or rod offered great advantages. The smallest railway involved embankments, cuttings, and bridges, fencing, and the purchase of land. A single stiff rail, with numerous supports, from which the train might hang, seemed better, and may, in some cases, be employed; but the supports would require to be numerous—say, one post every 10 or 15 feet—and even with these spans the girder required to carry vehicles weighing 2cwt. each would be costly. With a single suspended rod or rope we may have supports 60 or 70 feet apart. A ¾-inch rod, thus supported, will carry five vehicles, each bearing 2cwt., without excessive strain—no purchase of land is necessary, no bridges, earthworks, or fencing. The line could be removed from the ground so far that it would not be meddled with either by men or animals.

A single wheel-path gives the minimum of friction, and the rolling stock would be much more easily managed than if we attempted to let vehicles run on double swinging ropes. On all those grounds it seemed well worth while to devise means by which trains could be electrically and automatically driven along the single suspended rod.

Before proceeding further I had better state how far this idea has been realised. The Telpherage Company (Limited) was formed last year to test and carry out my patented inventions and those of Professors Ayrton and Perry for electric locomotion. On the estate of Mr. M. R. Pryor, of Weston, two telpher lines, on my plan, have been erected. One of these is a mere straight road, with spans of 60 feet, and various forms of rod and rope. The first full-sized train was run on this line with a locomotive which we call the bicycle-wheel locomotive. The line was found inconveniently large and high, and the experiments were continued on a line ⅝-inch diameter, of round steel rods, with 50 feet span. This line is continuous, that is to say it re-enters on itself. It is 700 feet long, and we have run a train of more than one ton at a speed of five miles per hour on this line with complete success. The insulation has given no trouble. It need hardly be said that we see our way to great improvements in details. Thus, we can make the road more uniform and stronger for its weight; we can lessen the quantity of material used, and greatly diminish the amount of skilled labour required in erection. We can improve the design of the posts. We can improve the trucks and locomotives so that they will go round sharper angles, and so forth, but the main object has been practically carried out. We have had trains, on a scale as large as I am prepared to recommend, running at the highest speed I have contemplated.

I trust it will be clear to you from this description that what I have contemplated and realised is not an electric railway destined to compete with steam railways in conveying goods and passengers at high speeds, neither is it a new form of communication destined for small parcels and high speeds; it is simply a cheap means of conveying heavy goods which, like coal or grain, can be carried in buckets or sacks each containing two or three hundred weight. The speed on a telpher line will be that of a cart, and the object we aim at is to cart goods at a cheaper rate and more conveniently than with horses.

I will assume that you all know that an electric motor is a machine which will run so as to exert power whenever an electric current is passed through it. You also know that a machine called a dynamo, driven by a steam-engine or other source of power, will produce an electric current which may be conveyed along a suspended and insulated rod, and used to drive an electric motor.

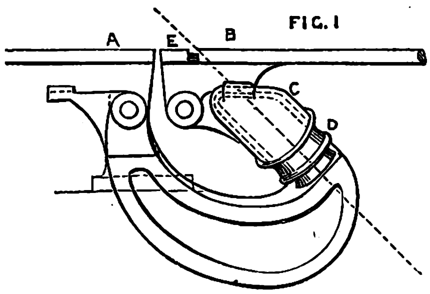
In describing the details of my system the first point to be explained is, how the current produced by the dynamo, and conveyed along a single line, is taken from that line and directed round the motor.

* Paper read before the Society of Arts, Wednesday, May 14, 1884.

Digitized by Google

In endeavouring to realise this idea, the first thought which occurred to me was that of dividing the line into lengths, equal to the length of the train, so that using the train to bridge over a gap between two sections at different potentials, the current could be conveyed from the leading to the trailing wheels of the train, round the motor. This idea is employed in the model now shown; but, in the first form which suggested itself, the gaps between the sections were opened by a switch worked by the front of the train, and closed by a switch worked by the end of the train. The first model, which may have been seen by some present working in Fitzroy-street, was made on this plan. Trains driven in that way would all be coupled in series. The present model is differently arranged; there are no working parts or switches. Let the successive sides of the polygon be called the odd and even sides; the odd outer sides are connected with the even inner sides, and the even outer sides with the odd inner sides. We thus have two continuous conductors each going right round, but not joined to each other; these are connected to the two poles of a battery. So long as no train bridges a gap no current flows, but whenever the train bridges the gap, a current

FIG. 1



flows from the positive to the negative pole round the motor. This plan is called the cross-over system; all the trains are joined by it in parallel arc, and the current is reversed each time a train passes a gap. This reversal does not affect the working of the motor. This is the plan which has been carried out on a large scale at Weston. Its simplicity leads me to believe that it will be the plan most usually adopted, but several other methods of driving have been devised. A spark passes between the wheels and the line each time the current is stopped; but this spark occurs between large masses of metal, where it appears to be harmless; it has given no trouble whatever at Weston. Moreover, it has been found very easy to make connection between the line and the train. The ordinary truck wheels answer admirably, so that no complicated brushes are required. There are some absolute advantages in the interruptions occurring at regular intervals, but the discussion of these would lead me too far for my present purpose.

Only one of the two continuous conductors requires to be insulated; this results in alternate insulated and uninsulated sections all along each line. Fig. 1 shows a saddle, as we call it, with an insulated attachment at the one end and an uninsulated attachment at the other, as used for a short sample line which has just been

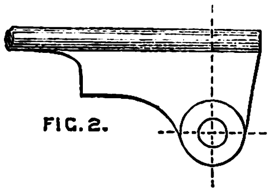


FIG. 2.

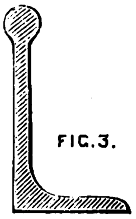

FIG. 3.

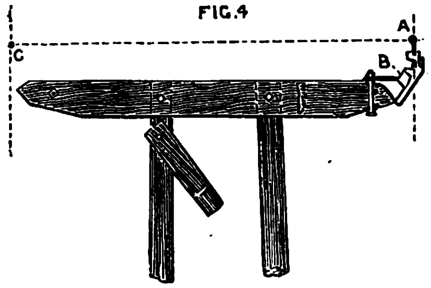
sent to Peru for the Nitrates Railway Company (Limited). The line itself is a three-quarter inch steel rod with forged ends, and the figure sufficiently shows the mode of attachment. The insulation is given by a vulcanite bell insulator. All the parts are designed to stand 2·2 tons strain; the vulcanite is secured between two layers of Siemens cement. The experiments at Weston have shown that vulcanite answers perfectly, but the material is rather expensive. I have here a smaller porcelain insulator, which has been subjected to 2·2 tons strain. I believe porcelain will answer well in all respects, but it has not yet been subjected to the test of actual traffic day by day. At Weston the vulcanite was used between layers of Portland cement, the only objection to which is that it takes some time to set. The simple steel rod has been found preferable in all ways to rope. We find that there is less friction and less jar with the rod, and ample flexibility; it is also much easier to secure. Moreover, a solid rod with welded ends can be made so that the ends, where supported, are, to some extent, undercut, and this allows much greater freedom of rolling than would be compatible with the horizontal gripping wheels, especially when gripping wheels are used which, like those in the model, actually hold on to the line so as to resist being lifted.

Fig. 4 shows the posts and crossheads supporting the line. In the one-inch example this design was fully carried out, and the posts stood the cross strain due to the overhanging load perfectly. In the five-eighth line an attempt was made to cheapen the construction, but the posts in wet weather work at the foundations. It is well that we are put on our guard against this danger. In the

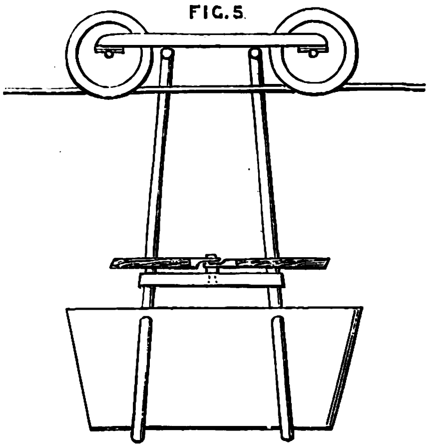
FIG. 4



first design a sort of rocking saddle was employed, to allow the strain to be transmitted from one span to the next, but the flexibility of the posts provides amply for this object.

Abutment posts are required at intervals, and these can be made use of to provide compensation for changes of temperature, and to limit the stress on the rods. In straight lines I reckon about four abutment posts per mile.

FIG. 5.



In the short South American line curves of 45deg. at the posts will be employed, as shown in the model. At the stations, where goods are to be handled, rigid supports will be more conveniently employed. A bulb angle-iron like that shown in Fig. 3, supported every ten feet, answers well at Weston, and a siding, leading the trucks off this line, has been satisfactorily carried out. The siding leads back to the line at a point between two flexible spans. In fine, it may be said to-night that the problem of the continuous

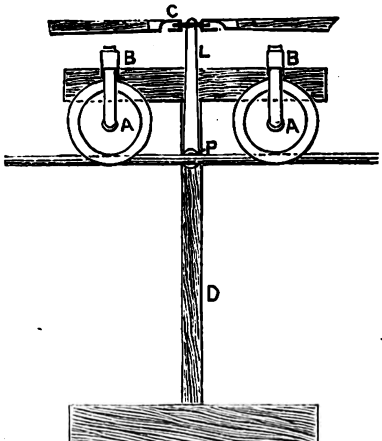


Fig. 6.

line, whether straight, curved, rigid, or flexible, has been completely solved. Drawings and specifications can be put, without further delay or experiment, into the hands of contractors.

Trucks used on ordinary rope lines are designed to be pulled by ropes on a road which is necessarily straight. When trucks of this description, with wheels 8in. diameter and 22in. wheel-base (Fig. 5)

Digitized by Google

were tried at Weston, arranged in trains, some new difficulties presented themselves. Any sudden check to the motion was followed by a rearing action, throwing the truck off the line; similar results followed the application of any sudden pull. Moreover, trucks with two rollers on a rigid frame, even with so great a wheel-base as 22in., require curves of considerable radius if we are to avoid serious binding at the flanges. Notwithstanding these difficulties, the trains at Weston with a little care run well and lightly, but the trucks which have gone to South America are on the plan adopted in the model, and run much more safely and turn much sharper curves. They have two peculiarities—first, each wheel 7in. diameter (Fig. 6) is pivoted on an axis, B, vertically over the centre of the wheels, A; this allows the truck to run with the freedom of a bicycle round curves; secondly, the weight carried is hung on a swinging arm, D, pivoted to the frame at a point, P, on a level with the line. The result is that any force applied in a plane containing the line acts as if applied at the line itself, and will neither lift the wheels in front nor behind. In the model the coupling, as you see, is attached to the top of the swinging arm, where the coupling rods are well out of the way. The swinging arm, moreover, relieves the locomotive from all jerk at stopping or starting.

(TO BE CONTINUED.)

LEGAL.

Wandsworth District Board of Works v. the Postmaster-General.

On Tuesday, Sir F. Peel, in delivering judgment, reviewed the facts of this case, and in the course of the judgment he stated that the Commissioners had gone over the ground in order to inspect the places in Wandsworth (Old), Battersea, Clapham, and Tooting, where lines of wire, in circuits extending from three miles and a-quarter to eight and a-third miles, were proposed to be erected overhead. The circuits are primarily required for fire brigade and police purposes, and the circuits proposed to be made would consist of 16¾ miles overhead, and three and a-half miles underground. The underground laying was limited, inasmuch as the cost was £350 a mile, as against about £8 a mile for overhead wire, and if all the wires were to be laid underground the service could not be carried out. The underground laying was generally limited to places where there were more than five wires to be carried; and the Post Office engineers gave cogent objections against the general adoption of a mixed service of overhead and underground wires. The appeal was heard before the Commissioners under the Telegraph Act of 1878, which made them the arbitrators where the parties could not agree to the terms of a stipendiary magistrate or County Court Judge. The Commissioners examined the objections of the District Board, and the views of the Post Office engineers in great detail. They pointed out that the estimates showed that the cost of an overhouse line was about one-third the cost of a line on poles if the poles were of wood, or one-seventh if the poles were of iron, while underground work, as compared with overground work, would be at least 30 times more expensive. There were sections of each proposed circuit, where, it seemed to the Commissioners, wires might be put overhead as safely as if the roads were quite in the country, and under these circumstances, and taking the cost into consideration, the Commissioners could not agree with the District Board that the underground system ought to be made compulsory throughout the Wandsworth District. On the other hand, the Commissioners thought that overhead wires ought not to be put up except upon conditions which would give assurance of safety, and the judgment therefore added to the conditions laid down by Mr. Paget. The routes were marked out in detail, and the Commissioners laid down that the distance between the points of support on either side of a public road or street should not exceed 100 yards. Costs were asked for on behalf of the Post Office, but the Commissioners declined to make any order in respect to costs.

United Telephone Company v. Hebden.

In the High Court of Justice a few days since, before Mr. Justice Pearson, Mr. Cozens Hardy, Q.C., and Mr. Moulton moved, on behalf of the plaintiffs, for an order to commit the defendant to prison for disobeying an injunction restraining the infringement of the plaintiffs' patent by selling telephones in imitation of Bell's telephones. Evidence was produced in support of the application.—Mr. Renshaw, for the defendant, endeavoured to show that there had been no conduct on his part which would warrant his committal.—Mr. Justice Pearson said it appeared that the order for an injunction restraining the defendant from infringing the plaintiffs' patent was made by Mr. Justice Fry in December, 1882, and in February, 1883, that learned judge made an order for the committal of the defendant to prison for disobeying the order. An application was made on the 10th of March for his release, but Mr. Justice Fry refused the application. Subsequently, however, an order was made for his release. There was no doubt whatever, in his lordship's opinion, that the defendant had now committed a gross contempt of court in again disobeying the order restraining him from infringing the patent. The evidence was quite sufficient to prove that the defendant had been purchasing instruments similar to Bell's patent telephones, which had been manufactured at Rotterdam by an American company, and these instruments had been sold by the defendant in this country. Under these circumstances he should make an order for the committal of the defendant to Holloway Prison.

London Platino-Brazilian Telegraph Company (Limited).

The sixth ordinary general meeting of shareholders of this Company was held at the offices, No. 66, Old Broad-street, on the 22nd inst., under the presidency of Mr. Pender, M.P.

The SECRETARY (Mr. William Payton) read the notice convening the meeting and the minutes of the last ordinary and extraordinary general meetings, which were confirmed. The report of the directors was taken as read.

The CHAIRMAN: Gentlemen, before asking you to approve the report I beg to make one or two remarks. As you are aware, the gentlemen who are sitting at this Board some very few years ago rescued this Company from what I may call a total wreck, and since that time up to the present we have been paying 2¾ per cent. I may say that that 2¾ per cent. was paid upon a cost which probably, if the business had been carried out in a business-like way in the first instance, would not have been half the amount of the capital expended. However, that is a thing of the past, and a matter with which your Board had nothing to do. We came in in the interests of the shareholders—of the large shareholders, and some of the small shareholders—to rescue a concern which, as I have said, was drifting entirely upon the rocks. We are not managers of the Western and Brazilian cables—we have nothing to do with that company's cables; and on the good or bad management, or on the success, of the Western and Brazilian Company depends our dividend. Neither are the Western and Brazilian Company dependent on themselves, because their dividend is more or less earned from the success of the Brazilian Submarine Company. Well, the reason we are paying a smaller dividend this year, or one of the reasons, is that the Brazilian Submarine cable was interrupted for two months, and the result has been that the proportion we receive has been reduced, owing to that interruption, to £12,638, or a decrease, as compared with 1882, of, in round figures, £3,000, or just about ¾ per cent. dividend on our capital. This explains the reason why we are paying a smaller dividend to-day than we did this time last year, and it is a matter over which we have no possible control. The bright feature, however, in the case is that the Brazilian Submarine Company are duplicating their cables, and I have found from my experience in connection with submarine cables that unless your system is duplicated you can never trust to what I call a steady and continuous income. An interruption of two months is not merely the loss which is sustained by that interruption, but the influence it has in throwing back the spirit of telegraphy, which is very considerable. Telegraphy is now more or less conducted in the interests of commerce. They use it to a very large extent, and when men get accustomed to it and a break occurs it throws them back on their old ways of dealing with business, and that retrogression has to be made up again. I merely make these remarks because there are gentlemen present who have not always the opportunity of watching as closely as I do the effects of breakages of submarine cables. As, however, I said just now, the Brazilian Company are duplicating their system, and we may look to that fact for a more steady income in the future. The next point to which I wish to draw your attention is the Government debt. It appears as £7,360, and it is the debt due to us by the Uruguayan Government. We are trying to obtain that amount, and we are hopeful that before this year is out we shall obtain a settlement. The last information we have on this subject is as follows:—"Finance Minister to-day interviewed. Chambers have not yet sanctioned law proposed by Government to settle our old credit receiving unified debt at par without interest accumulated, but Minister expects will be sanctioned before end present year." Therefore, as you see, we are carrying on these negotiations, and I am hopeful that they will be carried on with success. With respect to the competition we meet with from the Brazilian Government, I have always stated, and I repeat it now, that I do not think the Brazilian Government have kept faith with those who have laid the submarine telegraph system. The Emperor himself told me that if we carried out the system to the Brazils we should have every possible encouragement on the part of the Government—that they could give us no subsidy, but that they would give us fair play and virtually a monopoly of the system. Instead of that they have started land lines to compete with the submarine system, and the result has been to lower the tariffs very considerably. The submarine lines are now obliged to compete with the Government, and the Government with a long purse behind them are competing at a loss, doing no good except to those who use the telegraphs, and inflicting considerable harm on the companies. I believe that the Western and Brazilian Company are keeping that matter constantly before the Brazilian Government, and I hope that the day will come very soon when they will be shamed into doing what is right. The next point is the question of the Six per Cent. debentures. Last time we were here we discussed that question, and after a good deal of consultation endeavoured to do the best we could for the Company. We succeeded in issuing our debentures at 6 per cent. instead of 7 per cent. I think the price we issued them at was a fair one as between those who received them and ourselves. We are, I think, entitled to the confidence of the public. I think these 6 per cent. Debentures are a very good investment indeed, and I am hopeful that they will be proved to be so by those who have obtained them, placing them in such a way as will be profitable to them and those who invest in them. As stated in the report, a difference has arisen between the Western and Brazilian Company and this Company. You are all aware that we receive from the Western and Brazilian Company a proportion of the gross revenue of that Company, and the difference of opinion which has arisen is as to whether the income does not admit of being looked at from two points of view. They have taken their view and we have taken ours, and they differ; but there are men of business at their Board, and I hope there are men of business at our Board,

Digitized by Google

and I trust that we shall be able to settle this point on a fair basis. I can assure you of one thing as to this matter—namely, that knowing our position to be a strong one, we are not likely to make any concession which would be injurious to your interests, and your interests will be our first consideration in the settlement of this question. I do not think I need go further into the details of the question, and I think I have now exhausted all the points that I wished to bring before you. With these remarks, therefore, I will now move "That the report and accounts for the year ending 31st March, 1884, submitted to this meeting be and they are hereby received and adopted, and that a dividend of 2s. per share be declared, payable this day, free of income-tax."

Mr. JOHN HOLLOCOMBE seconded the motion.

Mr. ROBINSON KENDAL: Have the debentures been issued for any number of years?

The CHAIRMAN: Yes, for twenty years.

Mr. A. BAKER stated that at the last meeting he rather criticised the conduct of the Board in the placing of the debentures, but looking at the report, he thought that the amount charged for the issue was exceedingly small. In view of what he might have said at the last meeting, he felt very much pleasure now in saying that he thought the debentures had been issued as cheaply as possible. With regard to the difference with the Western and Brazilian Company, it seemed to him that it would be a great pity if they were obliged to go to law, and he should imagine that a settlement might be arrived at by a friendly arbitration between some of the members of the two Boards.

The CHAIRMAN: I think Mr. Baker takes just the business view of it that I took. As I said, there are business men on the Western and Brazilian Board, and on this Board, and though I will not say it would be discreditable, it would not be complimentary to us if we do not settle this matter ourselves. There are times, however, when the lawyers must be called in, but we will not do so unless we are compelled. We are, however, determined to protect your interests, and if our judgment is right we shall stand by our judgment.—He then put the motion in the usual manner, and declared it carried unanimously. Continuing, he moved the re-election as a director of Mr. Hollocombe. He said: Mr. Hollocombe's knowledge of Brazilian affairs has been most valuable to the directors, and I can assure you as chairman of this Company that I always feel that it is desirable to have about us some one who has special knowledge of the affairs and interests we have to deal with.

Mr. FRANCIS PAVY seconded the resolution, which was carried unanimously.

On the motion of Mr. W. FORD, seconded by Mr. KENDAL, the auditors, Messrs. Deloitte, Dever, Griffiths, and Co., were next reappointed.

Mr. KENDAL then moved a vote of thanks to the chairman and directors for their management of the affairs of the Company during the past year. He thought they had carried out the issue of the debentures very successfully, and in a manner highly advantageous to the Company. He regarded the charge of issue as very small indeed.

Mr. BAKER seconded the motion, which was carried unanimously.

The CHAIRMAN: I can assure you on the part of my colleagues and myself that we feel gratified by this expression of your opinion. We had a discussion at the last meeting on the subject of the issue of the debentures, and I think I then assured you that the interests of the Company would be safely conserved, and that we should be able to stand before you to-day and state that we had dealt with this transaction in a fair and business-like way. We have now your approval for having carried out this matter properly, and you can well understand that we are satisfied because you are satisfied. We believe that the business is fair as between man and man, and I have only to say that, looking at what is behind us, I do not know that there is any better debenture in the market than these. Six per cent. is not so easily got in these days. At the same time it has been beneficial to us, as we have reduced the rate by 1 per cent., and have thus established our credit on a firmer basis. I do not say there is a great prospect of obtaining a very large dividend from this concern, but now that the interest is reduced I think we can show that on the market price of the shares it is a very fair dividend. This concern, as I have said, cost more than double what it ought to have cost in the first instance, and at the price of the day there is something like the value of the concern. We give at the price of the day something like 4 per cent., and I see no reason why there should not be a moderate increase on that. I beg to thank you, gentlemen.

The proceedings then terminated.

The West India and Panama Telegraph Company (Limited).

The fourteenth ordinary general meeting of the members of this Company was held at the City Terminus Hotel on the 21st inst., under the presidency of Mr. C. W. Earle.

The SECRETARY (Mr. R. T. Brown) read the advertisement convening the meeting and the minutes of the last meeting, and the report of the directors for the six months ending 31st December was taken as read. It stated that "the amount to credit of revenue is £45,218 5s. 1d., and the expenses have been £20,617 15s. 2d., leaving a balance of £24,600 9s. 11d., which, with the balance of £3,287 15s. 3d. brought from last account, makes an available total of £27,888 5s. 2d. Of this sum the directors have placed £15,000 to reserve, leaving an available balance of £12,888 5s. 2d., which it is proposed to deal with as follows:—Payment of 6s. per share on account of arrears of dividend on the first preference shares, £10,368 18s.; balance to current half year's account, £2,519 7s. 2d."

The CHAIRMAN: The report divides itself as usual with us into three headings—first, financial; second, engineering; and third, what I may call plomatic, which means our relations with the fifteen different colonial governments and three home governments; and a very heavy task it is. As far as the revenue goes there is some satisfaction in seeing a small increase in the traffic—an increase of £4,174. I do not know that there is any special reason to account for this. I suppose it is one of the incidences of the West India trade—the sugar trade. Perhaps it was better in that period, the last part of last half year, than it has been. With regard to the expenditure there is also a saving in comparison with the corresponding period of £6,693. To a small extent this is owing to reductions we have been able gradually to effect in the current expenditure, but the bulk of it refers to the expenses of the ships, and the saving there is to a great extent accidental, for the "Grappler," which came home to be repaired, was employed by us in taking out new cable. The expense of that freight goes to the credit of the "Grappler," and to the charge against the cable when it is used. Therefore the expenses of the "Grappler" have been *pro tanto* less than if she had been stationed in the West Indies, and the cost of the cable she expended on the San Juan-Jamaica cable, to which I shall allude presently, is charged to the reserve fund, being practically a renewal, and therefore a fair charge against the fund, which was established for the purpose of renewals as distinguished from repairs. The "Grappler" was overhauled and put into thorough repair for the sum of £886, which I think was a very moderate amount. For the smallness of the amount we are very much indebted to Mr. Holmes, who is a practical man with regard to shipping, having been the owner and commander of ships, and that gentleman passed a great many days, and I may say a great many nights, on board that ship, superintending everything that was done in the way of repairs at that time. While on the subject of the amount I may call attention to the reserve fund, which up to the 31st December last had been invested in good securities to the amount of £55,255. Since then we have put an additional £26,000 into like securities, but as it was done after the end of last year it does not appear in this report. It is, however, satisfactory to think that we made this investment before the late rise in that class of stocks consequent on the announcement of the Chancellor of the Exchequer's views as to consols, and there is a profit of £2,500 on the investments we have made on account of the reserve fund. As to the repairs of the San Juan cable I am sorry to say that they promise to be more expensive than we anticipated. Last time I had the pleasure of meeting the shareholders the ship was just about starting to conduct the operations on that cable. In the meantime, before she had arrived, we had repaired the end of the cable nearest to Porto Rico. We had used the "Duchess" in a leisure moment to look into the matter, and she had got 45 miles in that cable. The "Grappler" came and joined up at the end of the 45 miles, and laid about 125 miles to the westward. She then came to a break and joined up the cable there; and in going to the westward again she found the cable so decayed that it broke seven times before they got it to the top. That proves that that cable must be relaid. While she was engaged on this operation the Jamaica-Colon cable failed, and we had to send her there, and she has not been able to return to the San Juan cable. At this moment the two cables belonging to the International Company are broken, and we have chartered the "Grappler" to go to repair them. This will give us a little profit this half year, and compensate us to some extent for the falling off that has taken place in our traffic, owing to the depressed state of the West India trade. Sugar has never been known to be so low as at this moment, and the result is that our revenue from traffic this half year is about 15 per cent. in arrear of what it was in the corresponding half of 1883. On the other hand, I have the satisfaction of reporting that the Demerara cable is repaired. We now come to the questions of the subsidies, the West India Commissioners' report, and our relations with the Governments generally. The present position is pretty clearly laid before you in the report in paragraph 4. We have got the assent of all the colonies that were represented at the Telegraph Conference in Barbadoes in 1882 to give us an increase, with the exception of Barbadoes. Barbadoes stops the way. The Government of the Leeward Islands say that they will not pay us an extra subsidy unless the increase be universal, and Barbadoes says that nothing at present will induce them to give an increase. Why Barbadoes takes this line I cannot say. Barbadoes has always been particularly opposed to us, and as the service there is performed in exactly the same way as at the other stations, I cannot really account for the difference in the feeling and sentiment there towards the Company. I am afraid it is in connection with that serious obligation which is on us of the news bulletin. The press of the island are constantly writing against us with the view of getting more news. Their object is to get long cable telegrams for nothing. This would increase the sale of their papers, and their cue is to be writing down the Company for the insufficiency of the news forwarded. Sometimes their charges against us are grotesque. In December last, for instance, we were strongly condemned for not sending them the Queen's Speech! With regard to the report of the Royal Commissioners, I was in hopes that something more favourable towards us would have come from their investigations. You see what they have written about the islands of the West Indies (displaying Blue Books). All the preamble till they come to the conclusions is very decidedly favourable to us. In talking of Jamaica they say, "The subsidy to the West India and Panama Company we consider to be for the benefit of the island generally." One of the witnesses in Jamaica said he was against subsidies, but he stated that it would be unwise to give up the subsidy to this Company. In St. Lucia they say "the expenditure on telegraphic communication is of great importance to the commercial interests of this island." One of the witnesses, a Mr. Hughes, said, "I do not think this

Digitized by Google

expenditure (meaning our subsidy) can be safely dispensed with, and though the public generally may not use the system (and they do not), it is of great convenience." But then what is the outcome of all this favourable mention of the telegraph to the West Indies? I will read the summary of the commissioners. They say:—"The general commercial progress of these islands is dependent to a very great degree on trustworthy and continuous telegraphic communication, which is daily becoming more and more indispensable to the administration, commerce, industries, and indeed security, whether in the event of riot or of war, of our West Indian colonies. At present this communication among the various West Indian islands is provided by the cables of the West India and Panama Telegraph Company (see map No. 3). There have been many complaints of too frequent interruptions of communication, which, we were informed, had prevented merchants and others making such use of the telegraph as they would otherwise have done; but by the repair of old cables and the laying of new we are informed this system has now been placed in a satisfactory condition. But this system is connected with America, and so with Europe, by lines that run across Cuba to the United States, on which the charges for transit of messages are heavy, nor is there at present any alternative route in case of breakdown or war. We are of opinion that the West Indian telegraph system shonld be connected as soon as possible with North America, as well as with Europe, by a direct cable to Halifax *viâ* Bermuda, and that on the laying of this cable the West Indian colonies might, if necessary, well increase their subsidies, while other subsidies could be added from Bermuda and from Nova Scotia. At the same time, in order to secure the prompt laying of the cable, we are of opinion that both the Imperial and the Colonial Governments would do well to guarantee interest to a moderate amount on the capital required for the new cable for a certain term of years. Were this accomplished a profitable reduction in the tariff might well follow; communication would be absolutely reliable, and with these reforms we think the telegraphic companies would find the business amply remunerative; but we are of opinion that if such reductions in the tariff are contemplated, there should be no longer a demand for the supply of bulletins of news daily, and free of charge, by the Company, as is now the case. This demand trenches greatly on the legitimate income of the Company, and although by this means steamer companies and newspaper proprietors are relieved of certain expenses, we fail to see why the colonists in general, and this particular telegraph company should be saddled with the cost. We are not aware that such conditions are imposed elsewhere. The Company, it appears, is put to considerable expense to obtain bulletins of news for the English as well as the foreign islands; but as the same news is telegraphed to all, the French complain at the excess of English news, and the English at the excess of French news. We are of opinion that it would be far preferable in any new arrangements to omit any conditions as to the supply of gratuitous news. We would add that it would be greatly to the interest of the Canadian Dominion to secure such direct telegraphic communication, as it would assist to open up the natural trade between Canada and the West Indies, which already grows fast in the exchange of salt fish and flour for raw sugar and tropical products." You will observe upon this that their suggestion of any increase, any assistance, any relief to the Company is made dependent on our constructing, or some one constructing, 2,000 miles of cable in the deepest water in the world, between St. Thomas and Halifax, Nova Scotia, to carry the insignificant traffic of the West Indies, and on the reduction of the tariff on our own lines. It is a recommendation which means, "If you cut your own throat we will see if we can do anything to help you." As to reducing our tariff, if we did that we should be in a worse position than we are now. Every reduction of tariff that is made shows that it does not raise the traffic of the company doing it. As to this direct line giving us any increase of traffic, I believe it would be futile to expect such a thing. If you could telegraph almost for nothing between our system and Halifax I do not believe the intercolonial traffic over our lines would increase to any appreciable extent. We shall prepare a reply to Lord Derby on this report of the commissioners, but I must repeat the regret we have expressed in our report that, when every little petty question of roads, of subsidies for the killing of rats, and for the supply of ice to these colonies was gone into and evidence taken upon it, this important enterprise had not the opportunity of stating its views to the commissioners. He concluded by moving the adoption of the report and accounts, and the payment of 6s. per share on account of arrears of dividend on the first preference shares.

Mr. Henry Weaver seconded the motion.

Mr. Griffith thought the shareholders were very much indebted to the chairman and directors. Their position was certainly not altogether what could be desired, but it was satisfactory to find that some of the West India colonies had a sense of honour, and that there was only one of them, Barbadoes, which resolutely persisted in doing what was despicable and contemptible. He thought it was incumbent on them to try and move public opinion on this question. Those who were members of the Royal Colonial Institute might raise the question there, and others who had connections with the West India colonies might also similarly use their influence in proclaiming the conduct of Barbadoes. By that means the colony might be induced to follow the example of the other colonies. He thought, however, that it was a much more serious matter to find that a report had been issued by the Government, which had, he maintained, altogether ignored the principles of justice. In our courts of justice and before Parliamentary committees of inquiry it was not usual to interfere with the rights of parties without hearing the other side of the question. The Company had not been heard on the questions dealt with concerning them by the Royal Commissioners on the West India Islands, and it was not right that they should be saddled with the additional obligations referred to. There was a kind of honourable understanding between the Colonies and the Company that assistance should be rendered to the Company in connection with the working of the cables; it was quite clear that unless the Government of these colonies kept to this honourable engagement, or semi-engagement, to assist them, the Company was likely to prove a failure, and those who had invested in it would in that case get no return. The idea of imposing on the Company the new obligations referred to was preposterous; and as a matter of expediency the proposal seemed to him an outrage on common sense, as well as an outrage on common justice. The proprietors ought to support the Board in the protest they were prepared to make, and unanimously help them in resisting a project which was, he contended, injurious, dishonourable, and altogether prejudicial to the best interests of the Company.

Mr. Veares believed that the directors thought they were doing right, but in his opinion the shareholders must look nearer home for some remedy to the existing state of things. Their hearts sank on reading the reports which the directors periodically presented to them; and with regard to the present report a pessimist might find a pasture ground in it, while an optimist could not discover a single gleam of hope. All the interests of the ordinary shareholders were practically mortgaged to the first preference shareholders. He thought a portion of the reserve fund might be employed in paying off the debentures, by which the interest on that head would be saved.

A Shareholder asked whether Barbadoes could not be cut off from the telegraphic conveniences given to them by the Company.

The Chairman: I am afraid if we were to do that we should find all the other colonies withdraw their subsidies. I do not know that there are any questions which I have to answer. As to Mr. Veares's suggestion to pay off the debentures with the reserve fund, I am afraid that would not be a safe course. The reserve fund is to meet any renewals or requirements with regard to the cables that may be necessary to keep the thing going, and if we applied that fund to the debentures we might be in a difficulty if we wanted £50,000 or £60,000. He then put the resolution, which was carried unanimously.

The retiring directors and auditor having been re-elected,

Mr. Griffith moved a cordial vote of thanks to the chairman and directors. The Company had the advantage of having the services of men of experience and tried character, and but for that fact he believed their success would have been still less. He had said that they had men of tried character at the Board, and as to that he had had the pleasure of listening to the masterly vindication by the Lord Chief Justice of England of Sir James Anderson.

Mr. Robinson Kendal seconded the motion, believing the directors were thoroughly well entitled to the thanks of the shareholders.

The motion was carried unanimously.

The Chairman: On behalf of myself and colleagues I beg to express our sincere thanks for the vote which you have just passed. We shall always do the best we can for you. We are only sorry that our efforts are so little successful after so many years of constant attention and work. As Mr. Ford reminds me, we shall press our representations on the Colonial Office as to what is stated in this report of the Royal Commissioners.

The proceedings then terminated.

Maxim-Weston Electric Company (Limited).

An extraordinary general meeting of this Company was held on Friday, the 16th inst., at the Cannon-street Hotel, Mr. Hugh Watt in the chair.

The Secretary (Mr. J. B. Cox) having read the notice convening the meeting,

The Chairman said that in moving the first resolution he might briefly repeat what he stated at the last meeting with regard to their determination to reduce the capital by £100,000. The balance-sheet issued for this year by the present Board dealt with the expenditure for two years, and it amounted to £32,283 13s. 3d., which of course had been carried forward, and they proposed wiping it off. The same thing was proposed to be done with regard to parliamentary expenses. The loss on stock and on re-valuation of plant and machinery was put at £16,757, and that might have been taken at a lesser sum, because at the time he took care to have estimates from various pepole to see what they considered it worth in the trade, and they had put the loss down at something like £2,000 in excess of those estimates. The surrender of the lease and building at Bankside cost £2,256. They used every possible means, and went to an expense of £20 to get rid of that lease. They were advised that the best plan was to relinquish the lease; but they could not get a single farthing for the sum expended, which was £1,800 and £500 premium, so that the sum of £2,256 became a total loss. Then as to the reduction in the price of patents, the present Board, considering that the sum at which the patents appeared in their books was in excess of their actual value, were desirous of bringing it down to what was their real value. As he explained at the last meeting the patents had been greatly enhanced in value by recent improvements. With regard to the incandescent lamp, they were out of the market with their own; though at the time it was the best. It required, however, an amount of current much in excess of more recent incandescent lamps, notably the Swan; consequently, when it became a question of installing so many lamps for a lump sum they were quite out of it, because their dynamos would not run the same number of lamps as other companies'. Well, they had got a new lamp—and on that he spoke very fully at the last meeting—that took less than half the current of the old lamp of 16 candle-power, but retained all the features of the old lamp, namely, purity and durability, durability being the main feature. The other lamps were usually described as high tension, inasmuch as they required 100 volts to each lamp. Of course that materially affected the durability, and he

Digitized by Google

might say that recently they had had many applications for their lamps to supplant those of other makers. As a rule the policy of the Board had been not to sell lamps, because the profit was infinitesimally small; the main profit was on the dynamos, and one reason why the profits of this Company during this present year had been satisfactory was that the new lamps enabled a dynamo capable of running 80 lamps to run 200. The old price of the dynamos he had been able to maintain, and in some cases to get more, but perhaps it was not judicious to go into details. Last year they sold an enormous number of carbons, of which they kept a large stock, and found it a very important item indeed. In one contract for carbons alone they cleared between £400 and £500 in five or six months, and he had every reason to believe that the Government who took those carbons would not only give them orders for further carbons but for a very large quantity of stock in the ensuing year. The carbons had been adopted in one of the departments of that Government, and arrangements were pending with them to take very extended plant indeed. He believed the shareholders would agree with him that it was undesirable to saddle the Company with such a large sum for patents as £100,000; they had reduced it to £70,000. Their new dynamo had been characterised by engineers and electricians as the best in the market. The reduction on shares received for licences and concessions was £17,171. Those were taken at par value in the last balance-sheet; but they were aware of the condition of electric lighting companies, and they were also aware that some of those shares had no quotation, so that in the event of their placing them on the market they would have to accept what was offered for them. They did not intend to place them on the market, but at the same time they had reduced them to 2s. 6d. in the pound all round. He thought that they were worth that, and that they might realise a little more. He thought they were entitled to take them at that, and the sum to be deducted was therefore £17,000. With regard to the loss on the new shares issued, the shareholders gave their consent to the shares being issued at 5s. They issued them, however, in the balance-sheet that had to be dealt with as £1 fully paid shares. The present Board, including Mr. Gray and his own friends, had subscribed nearly all those shares. He had no wish to take them, but the shareholders did not come forward, and they wanted capital. As the shareholders did not think proper to respond, the directors took those shares and had paid the debts of the Company and had gone on since. With regard to the profits, those profits had been derived from the sales of dynamos, lamps, carbons, new armatures, and so forth—out and out sales. They had fitted up about a score of complete installations, and he had now an order to fit up some large ironworks, and he had three or four promises. He always thought it better to go personally and arrange these matters. They had been lighting several places with great satisfaction, and he thought that during the year they would be able to show very good results. He honestly believed that they would be in a position in the current year to pay a dividend, and the shareholders might depend upon its not being paid out of stock. He moved "That the capital of the Company be reduced by £100,000 by cancelling paid-up capital which has been lost, or is unrepresented by available assets, to the extent of 10s. per share upon each of the 200,000 shares which have been issued and are now outstanding."

Colonel GILBY seconded the resolution, which was carried.

The CHAIRMAN said that the second resolution followed as a natural corollary on the first resolution, unless they made two classes of shares, for which there was no object. He moved "That the capital of the Company be further reduced by £150,000 by reducing the nominal amount of all the shares in the Company's capital from £1 to 10s. each, thereby leaving the nominal capital of the Company £250,000, divided into 500,000 shares of 10s. each."

The motion was seconded by Mr. Brown, and carried.

The CHAIRMAN said that at a meeting just held of the Lancashire Company the re-absorption of that company by the Maxim-Weston had been unanimously agreed to, and he thought that that measure would be in the interest of both concerns. There was no doubt that if all the shareholders in that company had paid up their calls, that would have been one of the most thriving companies in Britain—he might say in Europe. Unfortunately they did not pay. As it was the Lancashire Company was in a state of insolvency. Of course he did not look to the assets of that concern, but they took over a business that had been developed. There had been the foundation laid of a large business. They had lit the streets in Liverpool in a way that no company in Europe could do. Those streets had been lighted satisfactorily for two or three months without a single hitch, and the lights were beautiful. They had also opened up a business in private channels. One of the late directors had had his house lit up with 200 lights. That had been done on a sumptuous scale, and was admitted to be the most successful installation in the country. With regard to Manchester the installation there was simply beautiful, and there they had lit up some magnificent warehouses. He proposed the third resolution:—"That no further issue of shares in the Company beyond 50,000, making with the 200,000 shares already issued 250,000 shares, be made without the sanction of a resolution of the shareholders passed at a general meeting of the Company, to be duly convened for the purpose."

Mr. SWABY seconded the resolution, which was put and carried.

The CHAIRMAN said that by the absorption of the Lancashire Company they would have an important district, which in any other hands would have been futile, because in the event of the liquidation of the Lancashire Company the concession must revert to this Company. They got the plant of that company, which would be useful; the machines might not be in perfect order, but that they could remedy. He had made overtures to the Corporation of Liverpool, with the view of lighting such parts as would prove remunerative. He had seen the town clerk, who expressed himself very favourably with respect to the lighting, and also the electrician and engineer; but there was always some difficulty and delay in dealing with corporations. With regard to Liverpool the main difficulty in dealing with the Corporation was the all-powerful interests of gas. They admitted that the lighting was being carried on at a saving as compared with gas, and that they gave more candle-power. The difficulty in pushing their business was owing to the discredit attaching to other companies, and the numerous failures of the great bulk of arc installations. He was going north with the view of entering into a contract for the lighting of a theatre, an hotel, and another large ironworks, so that he thought he might safely augur for this Company a very successful future.

Admiral INGLEFIELD asked whether they made the carbons.

The CHAIRMAN replied in the negative, and said that they bought them and sold them at a large profit. With regard to the lighting of the "Gallia," he ventured to say that no steamer had ever been lit in a more satisfactory manner, and he had no doubt that other companies would adopt the light when the ship came back.

A vote of thanks to the chairman and directors then terminated the proceedings.

The Lancashire Maxim-Weston Electric Company (Limited).

An extraordinary general meeting of this Company was held on Friday, the 16th inst., at the Cannon-street Hotel, Mr. Wentworth in the chair.

Mr. REEVES (the solicitor) said that the liquidators had found it necessary to call the shareholders together for the purpose of placing before them a proposal which had been made to them by the Maxim-Weston Company for the purchase of all the assets of this Company. The proposal was one which the liquidators without the authority and sanction of the shareholders could not deal with or carry out. The Act of Parliament required that their authority and sanction should be obtained by means of a special resolution, and that made the present meeting necessary. In the opinion of the liquidators it was very desirable that this proposal should be accepted, and the arrangement carried through. As they were aware, the principal assets of this Company consisted of plant and machinery, which was useful only and could be used only for the purposes of electric lighting, and of the patents which were possessed by the Maxim-Weston Company. It was therefore very difficult, if not impossible, to find any person who would be willing to come forward and purchase at anything like a reasonable price such assets as those. The proposal which had been made by the Maxim-Weston Company was—that the Lancashire Maxim-Weston should sell and the Maxim-Weston Company should purchase all the assets of the Lancashire Maxim-Weston and all other the property and effects of the Lancashire Company of every kind and description whatsoever. The consideration of the purchase would be that the Maxim-Weston Company would pay all the debts and liabilities of the Lancashire Company, and would indemnify the Lancashire Company and the liquidators therefrom. The Maxim-Weston Company would give the shareholders of the Lancashire Maxim-Weston Company one share in the Maxim-Weston Company for every fully paid up share in the Lancashire Maxim-Weston; that was to say, the shareholders of the Lancashire Maxim-Weston would get share for share in the shares of the Maxim-Weston. That was the proposal, and it would be for them to consider whether in their opinion it was not very desirable that the liquidators should have power to carry it out.

The CHAIRMAN said that he could only add that he and his colleague had called the shareholders together after very carefully considering this matter, which was one of practical amalgamation with the parent company, and both Mr. Brown and he believed that that was the only course they could pursue. They had made overtures, unofficially certainly, to various people who might be likely to entertain the project of buying the assets of this Company without receiving any real response, and the only course they had open was to accept this offer, which he considered a very fair and liberal one on the part of the parent company. If that were not accepted they could only sell the plant for what it would fetch, and they knew what selling electric lighting plant would be. It would have to be done at a very great sacrifice, and he therefore very strongly recommended the shareholders to accept the proposals of the parent company, and he hoped they would do it unanimously, so that they might get to work as soon as possible under very favourable auspices.

Admiral INGLEFIELD said that, as a late director of this Company, he should like to make a few remarks. He would ask what had been done with reference to the claims they had on two gentlemen who were largely indebted to the Lancashire Company, because it was on the failure of their paying the calls on the shares allotted to them at their request that the Company found itself in the present position. At the last meeting the directors declared themselves, and were admitted by the Maxim-Weston, to be a flourishing concern, and if the calls he had alluded to had been paid the Company would now have been going on successfully. He asked what was the position of the Company in regard to the law suit with Messrs. Harding and Dadson.

A SHAREHOLDER asked if all the calls were got in what would be the condition of the balance-sheet—if it would show a debit or a credit balance? It was necessary that they should know that in order that they might know what they were handing over to the parent company. He also asked the liquidators if they had gone into the business of the parent company and satisfied themselves that the business was of a satisfactory nature, and that it was a thoroughly solvent concern that they were asking the shareholders of this Company to join. He presumed the liquidators had seen the working of the other company, and could assure the shareholders of the Lancashire Company that they were asked to transfer their business to a really sound and profitable concern.

The CHAIRMAN replied that the law suit was still progressing. He believed that some overtures had been made as to a compromise or settlement of those claims, but nothing definite had been arranged. They did

Digitized by Google

not consider, as liquidators, they could precipitate or push those matters unduly, and if the present offer were accepted the whole of the responsibility in regard to this matter would be thrown on to the parent company. As to the condition of the Lancashire Company, he must differ from the view of Admiral Inglefield. They might have pottered on, but they could not have carried on successfully. They might have gone on for two or three months provided they had got the calls in, but they had been suffering from the very first from an utter inadequacy of capital. They had only had about £8,000 of paid-up capital to undertake all the work that they had to do, and they could not have gone on on the limited scale they had been doing; and experience had proved that they could not make the thing pay without a considerable increase of capital, and with the discredit thrown on electric lighting generally it was hardly likely the public would put any fresh capital into the concern. He should have been very sorry to have asked any of his friends to have done so. The Lancashire Company, if rentals were going to be the thing of the day, was in a position second to none for carrying on a good business, but his experience of the last eighteen months was that rentals would not pay, and the sooner rentals were done away with the better. He did not mean to say that there might not be isolated cases where they might make a good contract and it might pay. They had one in Manchester, but so far as Liverpool was concerned it was his opinion, and it was the opinion of the directors of the parent company, that if they took over this business they would have to close the Liverpool business as a rental business. With respect to the real condition of the affairs of the parent company, of course he could not say that he knew any more than the general public who had the opportunity of looking at and inspecting their balance-sheet. His co-liquidator, however, was a director of the Maxim-Weston and might be able to answer the admiral's question. By special resolution they wiped off half their capital, and the 10,000 shares that were paid to them for the promotion of this Company were going to be wiped out, and the shares that would be issued would be shares of 10s. fully paid.

Admiral INGLEFIELD said that at a previous meeting it was stated that their light was so excellent that it had virtually swept away all opposition. That was said at a meeting of the parent company, so that it appeared that that and this Company were the best electric lighting companies in England.

The CHAIRMAN: I believe that.

Admiral INGLEFIELD said, that that being so, they were tenacious, first of all with regard to the directors, who he thought deserved some little credit, and secondly because they were going to sell a very excellent concern of high repute, share for share, to the parent company, which had a very large capital, and which was doing no business that he knew of.

A SHAREHOLDER asked if the claim against Messrs. Dadson and Harding was of so shaky a nature that there was any reason that they should compromise it. They had been told that the shares had been honestly and properly subscribed.

Mr. REEVE, the solicitor, said that as regarded Mr. Dadson, as far as he could judge of the case, he thought that the Company must succeed. He did not make the remark as at all doubting Mr. Dadson's position, but supposing that Mr. Dadson were able to pay, he had no doubt that the Company would recover.

A SHAREHOLDER: How much?

Mr. REEVE: The balance that was due—he thought about £2,000. With regard to Mr. Harding the case raised two questions, and he thought upon one it was extremely doubtful whether the Company could succeed in recovering—that was upon the promissory letters. That might involve a great deal of litigation, and the result he considered extremely doubtful. The Company might, however, succeed in establishing some sort of claim of that branch of their case; but with regard to the first part of the claim, that was to say, on the shares which Mr. Harding took clearly as a shareholder, he thought there could be very little doubt of that being in favour of the Lancashire Company. The amount of that would be about £1,200, and he was told there was a counter claim of £600.

Admiral INGLEFIELD: It is a very questionable one.

Mr. REEVES was not in a position to say much about that; but as regarded the Company's claim, that would be limited to the £1,200, and that he thought they might depend upon recovering, subject, of course, to any counter claim.

Mr. CAMPBELL asked the number of shares that were subscribed.

Mr. HUGH WATT: The number was about 15,000.

Admiral INGLEFIELD: It was under 15,000, but Mr. Harding pressed the directors to allot, as the number he said was certain to be made up.

Mr. HUGH WATT said that the present position of the Lancashire Company was such that it could not go on. Only that day they asked the parent company for a cheque to pay their wages. He wished to do the best he could for the Lancashire Company, because he himself and many of his friends were shareholders in it.

Mr. CAMPBELL thought that some explanation should be given as to how the profit shown in the balance-sheet of the Maxim-Weston Company was arrived at. He had seen a good many balance-sheets, and knew that unless they went into details they were not worth the paper they were written on. It might be correct, but they should have some explanation as to how the £5,000 profit was arrived at.

Mr. HUGH WATT: On sales.

Mr. BROWN: On sales of stock. That question was asked at the general meeting, and it was thoroughly explained to the satisfaction of all the shareholders present.

Mr. CAMPBELL said he was not a shareholder of the Maxim-Weston Company.

Mr. BROWN: If you read the report and balance-sheet I think it will be quite satisfactory to you.

Mr. CAMPBELL: I have read the report and balance-sheet, and can make neither head nor tail of them. How is that £5,000 made up?

Mr. BROWN: Those are sales actually made of dynamos, lamps, carbons, and other stock, engines, and so on—all new plant, or nearly new plant—4,000 to 5,000 new lamps.

Admiral INGLEFIELD said that as they were asked to sell their business to another company they ought to know the position of that company.

Mr. CAMPBELL asked what was the cost of the different materials landed in this country, and what was the amount they were sold for? If they knew that they would be able to judge what was the profit.

The CHAIRMAN did not think that they had any right to go into matters connected with the parent company. They were recommending them to take shares in the parent company, and they did so because they believed it to be a sound concern. He thought that Mr. Brown could reassure the shareholders generally without going into matters of detail.

Mr. CAMPBELL did not think that an explanation without details could be satisfactory.

Admiral INGLEFIELD asked if the Maxim-Weston was equal to carrying on the concern?

Mr. CAMPBELL knew that some time ago the report of the parent company told of immense success, and their report was absolutely unjustifiable by the facts. That was the report of a year ago, and without knowing something of the details he was naturally suspicious whether the same thing was not the case now.

Mr. BROWN said that a year ago he was not a director of the parent company, but he was not surprised at the remark that had been made. When he joined the Board of the Maxim-Weston the company was in a most hopeless condition. They had not money to pay the wages and had to borrow.

Mr. HUGH WATT: Who was the chairman then?

ADMIRAL INGLEFIELD said that he was chairman, and without his knowledge a circular referring to the condition of the Company was issued to the shareholders and read at the third adjourned general meeting. It took him completely by surprise. They were making a loss of £230 a week; but at the time of the annual meeting, of which he was then the chairman, they had a profit of £200 a week, therefore they had been brought to a very flourishing condition.

Mr. CAMPBELL said the managing director then was the same as the managing director now, and he declared then that there were immense profits; and as the same kind of statement was made now, was it not fair that they should ask for details when they knew that the statements made last year were not in accordance with facts?

Mr. HUGH WATT said that the statements made were in accordance with facts. The statement was prepared by Mr. Reeve, the then accountant of the company, and showed that for a month or two previous there were profits, but those profits did not cover the deficit. There were large sums owing, and they went to carry on the Company, till the end of 1883. Those profits were absorbed in carrying on the City installation and other ventures that had been gone into by the gentlemen they saw present.

Admiral INGLEFIELD: That I own, but you had been managing director for some considerble time.

The CHAIRMAN pointed out that this was a meeting of the Lancashire Company, and that the affairs of the parent company ought not to be brought up.

Mr. BROWN also argued that it was irregular to go into such details at this meeting.

The CHAIRMAN said that if they were not satisfied with the proposal they should refuse to ratify it, but he should like to know what better course could be taken. They had been going on from hand to mouth for the last two or three months, and it was now a question of amalgamating or shutting up their place and selling their stock for the best price they could get for it.

Mr. CAMPBELL thought it would be better to sell the Company if they could only get a shilling in the pound, rather than hand it over to a concern from which they might get nothing.

Admiral INGLEFIELD would like it to be understood that he was not opposed to amalgamation, but he wanted it to be perfectly understood what they were doing, and that they were offering their business for a fair remuneration.

Mr. HUGH WATT thought he was justified in asking the chairman whether, in the event of their plant being sold, they could pay their debts, much less a shilling in the pound?

The CHAIRMAN replied that that would depend upon how the plant was sold; if they sold it as a going concern they could pay their creditors, but he questioned whether there would be much for the shareholders.

Mr. THOMPSON, in reply to a shareholder, said that at present there was not much going on in Liverpool except stagnation. He honestly and truly believed the Lancashire to be the only practical and legitimate Company in existence—the only Company able to demonstrate that electric lighting could be done, and if they had had the sums due paid by the shareholders they might have gone on.

The CHAIRMAN said that if they wanted to know the condition of the Maxim-Weston they could not do better than go to the Stock Exchange, and there they would find that the shares sold at 4s. to 5s. They could from that gauge the value of their shares in the Lancashire Company in the event of an amalgamation. The present value of the shares of this Company was *nil*.

Admiral INGLEFIELD thought he might say on behalf of the late chairman that he was quite in favour of the proposal, seeing that they could not go on without money, and they had a difficult law suit hanging over their heads which might be extended for a considerable length of time. In fact the proposal was the only alternative to liquidation.

On the motion of the CHAIRMAN, seconded by Admiral INGLEFIELD, a resolution was then passed, accepting the proposal made by the parent company.

A vote of thanks to the liquidators then terminated the proceedings.

TO BE SOLD BY TENDER, in four lots, pursuant to an order of the Honourable Mr. Justice Pearson made in an action "Pedley v. Rogers and others," with the approbation of the judge, certain ENGINES, Machinery, Dynamos, and other Electrical Appliances and goods, situate at 57, Wellington-road, Barnsbury, in the county of Middlesex. Tenders are to be sent to Mr. Arthur Cooper, of 14, George-street, Mansion House, E.C., the Receiver in the said action, not later than JUNE 2, 1884, when they will be duly considered and be subject to the approval of the Judge at Chambers on Monday, June 16, at twelve. Catalogues and conditions of sale and forms of tender may be had of Messrs. West, King, Adams, and Co., 66, Cannon-street, E.C., Solicitors; of Messrs. Rogers and Chave, 3 and 4, Great Winchester-street-buildings, E.C., Solicitors; of Messrs. Pedley and Bartlett, of 23, Bush-lane, E.C., Solicitors; and of the Receiver.

SITUATION WANTED by ADVERTISER. Five years' experience; well up in all branches. Age 24.—TELEPHONE, 566, Wandsworth-road, S.W.

WANTED.—SITUATION as ELECTRICIAN, or Assistant Electrician, on board a cable ship. Advertiser well up in the practical testing of cables and the localisation of faults.—W., Office of *The Electrician.*

ENGLISH ELECTRICAL ENGINEER, about to visit America, is prepared to undertake the INTRODUCTION and PLACING of approved ELECTRICAL PATENTS and INVENTIONS in the United States and Canada.—Address, M.S.T.E., care of Willing's Advertising Offices, 125, Strand.

TELEPHONY.—ADVERTISER would be glad to COMMUNICATE with any Persons interested in TELEPHONIC MATTERS, especially as regards the existing monopoly in this country, or who have any inventions or ideas capable of development.—Address, J. K. D. MACKENZIE, 25, Queen Anne's-gate, Westminster, S.W.

TO ELECTRIC LIGHT COMPANIES.—It is proposed to LIGHT Four of the principal Hotels in Manchester from one contiguous centre.—For information and particulars please address to FREDERICK MURGATROYD, 6, John Dalton-street, Manchester.

4 CROMPTON PATENT "E" DIFFERENTIAL LAMPS, together with strong lanterns, suitable for outside use, FOR SALE, cheap.—Apply to D. C., care of H. Bennett and Co., 131, Hope-street, Glasgow.

FOR SALE.—A NUMBER of DIRECT and ALTERNATE CURRENT DYNAMOS and ARC LAMPS, chiefly by Siemens Bros.; little used and newest types; half price.—A. MACKAY, 104, Commercial-street, Dundee.

Just Published. Crown 8vo., cloth, 15s.

ELECTRICITY: ITS THEORY, SOURCES, AND APPLICATIONS.

AN ELECTRICAL POCKET BOOK

OF RULES AND TABLES FOR THE USE OF ELECTRICIANS AND ENGINEERS.

By JOHN MUNRO, C.E., and A. JAMIESON, C.E., F.R.S.E., M.S.T.E.

GENERAL CONTENTS: Units of Measurement—Measures—Testing - Conductors—Dielectrics—Submarine Cables—Telegraphy—Electro-Chemistry and Metallurgy—Batteries—Dynamos and Motors—Electric Lighting—Miscellaneous.

London: Charles Griffin and Company, Exeter Street, Strand.

J. EDMUNDSON and CO.,

ENGINEERS AND ELECTRICIANS,

19, GREAT GEORGE STREET, WESTMINSTER, S.W.

MANUFACTURERS OF

ELECTROLIERS, PENDANTS, AND BRACKETS, AND ALL DESCRIPTIONS OF ELECTRIC LIGHT FITTINGS.

SPECIAL AGENTS FOR HEDGES' PATENT SAFETY FUSES.

THE "SWAN" INCANDESCENT LAMP.

J. EDMUNDSON and CO. having been appointed as SPECIAL AGENTS for the Exhibition and Sale of the SWAN INCANDESCENT LAMPS, are prepared to supply these in any quantities. Also to furnish Estimates for fitting them up complete with all necessary apparatus. The Swan Lamps may always be seen in action at their Show Rooms.

NOTES.

ANOTHER PAPER.—The *Electrical Era* has been started in Philadelphia, U.S.

ELECTRIC LIGHT IN THEATRES.—The Teatro Reggio at Turin is now lighted by the Edison system.

MADRAS.—A new post and telegraph office has been opened in Madras at a cost of six or seven lacs of rupees.

POLICE TELEGRAPHS IN BOSTON.—Boston (Mass.) is going to spend 250,000 dollars on fitting up a system of police telegraphs.

ELECTRIC LIGHTING IN LIVERPOOL.—The Maxim-Weston Company have intimated their intention of discontinuing their lights in Liverpool.

PROVISIONAL ORDER.—Electric Lighting Provisional Order Bill No. 2 was passed through committee in the House of Lords on Friday, 23rd inst.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending May 23, 1884, amounted to £2,840.

HONOURS FOR ELECTRICIANS.—Sir William Thomson and Professor Edward Frankland have been named as honorary members of the Vienna Academy of Sciences.

SPAIN.—Heavy gales occurring last week in the south of Spain are reported to have done great damage to the telegraph lines, Madrid being quite cut off from the south.

NEW CABLE.—It is probable, says a contemporary, that Port Blair will shortly be placed in telegraphic communication with Burmah by means of a sea cable to Diamond Island.

APPOINTMENT.—Mr. T. Arthur Highton, late assistant secretary of the Jablochkoff Electric Light and Power Company (Limited), has been appointed secretary to the Piccadilly Art Galleries Company.

TELEGRAPH AND TELEPHONE POLES IN BROOKLYN.—According to an official report there are 5,817 poles and 3,001 miles of wire used for telegraph and telephone purposes in the city of Brooklyn, New York.

SPANISH NATIONAL SUBMARINE TELEGRAPH COMPANY.—This company have removed their head-quarters from Teneriffe to Cadiz. It is stated that the company have arranged to lay a cable from the Canaries to Puerto Rico.

MEASURING INSTRUMENTS.—We shall hope shortly to publish the paper recently read by Professors Ayrton and Perry, before the Royal Society, on "A New Form of Spring for Electric and other Measuring Instruments."

SIXPENNY TELEGRAMS.—Owing to the pressure on our space we are compelled to postpone the publication of Colonel Webber's paper on telegraph tariffs. We have, however, dealt with the subject in our leading article this week.

ELECTRIC LIGHTING BY PRIMARY BATTERIES.—On Wednesday Mr. I. Probert read a paper on this subject before the Society of Arts, Mr. W. H. Preece, F.R.S., being in the chair. We shall hope to find space for this paper in an early issue.

ELECTRIC LIGHTING AT TURIN.—It is stated that the Town Council of Turin have concluded a contract with the representative of Messrs. Siemens for lighting the Place Carlo-Felice in that city with Siemens lamps. The contract is to extend over ten years.

FURNITURE EXHIBITION.—In our note under this heading in last week's issue, the name of the firm mentioned as having carried out the electric lighting work therein detailed should have been Gretton, Mynn, and Co., and not Gretton, Thynne, and Co., as printed.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending May 23, 1884, were £2,256, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited).

THE WEST INDIES.—The cable between Trinidad and Demerara is repaired, but the cable between Key West and Havana is still interrupted. During the interruption telegrams can be forwarded without delay, *viâ* Galveston, to places in the West Indies and British Guiana.

NOTICE OF REMOVAL.—We are informed that the following companies—viz., the South-Eastern Brush Electric Light and Power Company, the Provincial Brush Company, and the Consolidated Electric Company, have removed their offices from 110, Cannon-street, to 68A, Cow Cross-street, E.C.

THUNDERSTORM IN VIENNA.—A telegram from Vienna, dated Monday last, says:—A violent thunderstorm passed over Vienna yesterday afternoon, doing great damage in the suburban districts. A young peasant was killed in his farmyard, and several houses in the same village were set on fire, one old man being burnt to death before assistance could be given.

LIGHT HEMP CABLES.—We notice that Mr. H. S. Baker has taken out a patent for covering of cables with plaited hemp. It will be remembered that Captain Trott, at the Society of Telegraph Engineers, not long since spoke very favourably of light cables, and of the lasting properties of hemp in sea water. Mr. Baker claims to have produced the type of cable there described.

THE TELEPHONE IN NEW YORK.—The *Pall Mall Gazette* is of opinion that the Underground Telegraph Bill, which has passed both Houses of Legislature in New York and only awaits the approval of the Governor, is enough to crush the life out of any undertaking. The Bill requires all wires connected with telephones, telegraphs, or electric lighting to be put under ground before November of next year.

ELECTRIC LIGHTING AT GREENOCK.—The Greenock Police Board have resolved to make some experiments in electric lighting. They are going to set up a 25 horse-power turbine at Prospect Hill filters, which is to drive a dynamo capable of feeding 100 incandescent lamps of 20 candle-power. Mr. Mavor, electrical engineer, of Glasgow, has been called in to advise the Board in the matter. The experiments are to cost £1,435.

OIL WORKS STRUCK BY LIGHTNING.—Lloyd's agent at Philadelphia telegraphed on Saturday evening, the 24th inst., that the Atlantic Refinery had been struck by lightning. Forty thousand barrels of petroleum were on fire, and the fire was spreading. Twelve tanks were reported to have burst. The city gasworks were endangered. The British barque "Faith" and the Italian barque "Emilia M." were towed to a safe anchorage. The shipping had sustained no damage.

ELECTRIC LIGHT ON SHIPS.—H.M.S. "Dolphin," Commander S. E. Wilmot, was to leave Sheerness for Suakin this week as soon as her electric light fittings could be completed. It is not so long since Her Majesty's Government ridiculed

Digitized by Google

the utility of the electric light in the navy, and yet here we find them actually delaying a ship in order to enable her to be fitted with electric light apparatus. Verily the ways of Government officials are tortuous and past finding out.

A BALLOON AND SIGNALLING CORPS.—It is stated that the formation of the new balloon corps in connection with the Royal Engineers at Chatham is now complete. The officers appointed to the corps are Major Elsdale in command, Major Temple, King's Royal Rifles, and Lieutenant Macdonald, Royal Engineers. The corps will consist of trained telegraphists, riggers, carpenters, and smiths, and they will have a distinguishing uniform. They will, it is understood, shortly leave Chatham.

THE NEW ATLANTIC CABLE.—A Reuter's telegram from New York, dated May 23, says:—"The 'Faraday' has laid a section of the new Atlantic cable from Dover Bay to a point 250 miles from Cape Ann, where the cable was buoyed. The shore end at Rockport was then laid, and the 'Faraday' proceeded to complete the section between that point and Dover Bay." A further telegram, dated May 28, says:—"The section of the new Atlantic cable from Dover Bay to Cape Ann has been completed."

HEALTH EXHIBITION.—Mr. Gooch, electrical engineer at the Health Exhibition, is using Mr. Killingworth Hedges' cut-outs and safety fuses in the machine room, the new galleries, museum, and other parts of the building. The street representing a bit of "Old London" was lighted up for the first time on Saturday by the electric light. The lights were not in view, so that the effect was as if the beams of the moon were falling upon the old buildings. Great satisfaction was expressed with the realistic effect.

RIVER PLATE TELEPHONE COMPANY.—The secretary of the River Plate Telephone and Electric Light Company writes that the settlement of the account with the Consolidated Telephone Construction Company, referred to in the report, having been found to require the confirmation of the shareholders of that company, and the meeting called for the purpose having been adjourned, it has been found desirable to postpone the meeting of this company, fixed for the 29th inst., until after the decision of the Consolidated Company.

LIGHTING GLASSWORKS AT NEW CROSS.—We understand that Messrs. Crompton and Co. have just completed an installation at the glassworks of Messrs. Fitch and Co., New Cross. Here one Bürgin-Crompton compound wound machine is used to supply current to two of the D D arc lamps, as illustrated in our issue of last week, and thirty of the Swan high-resistance lamps, known as 100 volt lamps. The arc and incandescent lamps are run on parallel circuits, which, although not entirely new, is certainly a somewhat novel feature.

FIRE ALARMS IN LONDON.—According to the report of the Metropolitan Board of Works for 1883 just issued, the past year has seen a still further extension of the system of electric fire alarm circuits, which are now an important feature in the machinery of the Metropolitan Fire Brigade. There are 23 fire alarm circuits in operation, the number of points at which an alarm can be given being 151. There are 64 lines of communication by telegraph or telephone between fire brigade stations, 17 between fire brigade and police stations, and 41 between fire brigade stations and public or other buildings.

ELECTRIC LIGHTING AT HAVRE.—A few days since the first trial of electric lights in Havre Docks was made. The large Eure dock is now lighted by Gramme lamps suspended from posts on either side. They can be lowered into the dock, which is a dry one, so as to give light to men working on a ship's bottom or sides, thus enabling work to be carried on by night as well as day, if required. The lamps have an illuminating power of 500 carcels, and will burn for seven hours. The plant was supplied and the installation fitted up by Messrs. Sautter Lemonnier and Co., the well-known electrical engineers, of Paris.

STORMS AND THE TELEGRAPHS.—In the House of Lords on Monday the Bishop of Carlisle moved for a return of the storms which had visited the British Islands between 1st January, 1874, and 31st December, 1883, and of which no warning had been issued from the Meteorological Office, with a notice of the quarter from which each unwarned storm had reached the coast. He pointed out that in 1882 ten storms of which no warnings were given reached our coasts. This was a serious matter, and he trusted that no mere question of money would prevent the increase of our meteorological stations and telegraphs. The motion was agreed to.

CITY GUILDS CENTRAL INSTITUTE.—We regret to hear that Dr. O. Lodge has withdrawn from the Chair of Physics at the City and Guilds of London Central Institution at Kensington, and we hear that Professor W. E. Ayrton, who was not originally a candidate for the chair, has accepted the professorship. It is understood that Professor Ayrton's numerous professional engagements led to his determination not to become a candidate. We think the original determination was a wise one, as we firmly hold that the position of professor is incompatible with that of an ordinary professional adviser. A professorship should be sufficiently valuable both as regards money and social position to render it unnecessary for the holder to mix with business pursuits.

EARTHQUAKE IN SOUTH AUSTRALIA.—A correspondent at Whyte Yarcowie sends the *Adelaide Observer* the following particulars of the shocks of earthquake experienced at that place on April 5:—"The weather was very close at the time (twenty minutes to 2 o'clock), and so very decided was the circumstance that we all looked at each other when seated at dinner to see if any one felt alarmed at a rolling as of heavy stones under our house. The shaking of the table and things upon it sent a most unpleasant sensation through us, and we immediately thought of Sunda and Ischia. Then there was another and more decided shock, which shook our house most perceptibly, and the neighbours ran out of their houses to see what stones had been thrown, or what heavy cavalcade was passing. A beautiful serene and peculiar pink atmosphere spread over our township until nearly 8 o'clock. An exceedingly heavy rain and vivid lightning, with loud peals of thunder, preceded these shocks, which seemed to travel from east to west in a belt, as the inmates of houses on the extreme south and north felt nothing peculiar."

ELECTRIC LIGHTING ON THE EMBANKMENT.—The report of the Metropolitan Board of Works for last year says that "the Victoria Embankment and Waterloo Bridge continue to be lighted by the Jablochkoff Electric Light and Power Company, under an agreement made by the Board with the Company in June 1881 for a term of three years. There are forty lights on the Embankment and ten on Waterloo Bridge, and the payment made is at the rate of 1½d. per light per hour. The Board has on several occasions lately [this presumably has reference to the latter end of 1883] had to complain of the sudden extinction of many of the lights during the hours when the

Digitized by Google

company is bound by agreement to keep them shining." Our readers will see on referring to our advertisement columns that tenders are invited for lighting the Embankment and Waterloo Bridge for a further term of years.

THE TELEPHONE IN ENGLAND AND AMERICA.—"J. W. B.," writing to the *Pall Mall Gazette*, says:—Mr. Fawcett last night, in answer to Mr. Gray, stated that the Post Office had been applied to for seventy-seven licences, and they have granted eight. He stated also on the 15th, in reply to other queries, that during the past year they had 954 telephones in use, as compared with 598 in 1883, and 177 in 1882. It may be instructive to compare these figures with those of the Bell Company of America, taken from their last report:—

	Jan. 1, 1883.	Jan. 1, 1884.	Increase.
Exchanges open ...	735 ...	890 ...	165
Miles of wire.........	69,452 ...	82,879 ...	13,427
Subscribers	97,735 ...	123,533 ...	25,798
Employés	3,704 ...	4,777 ...	1,073
Instruments	249,711 ...	307,010 ...	57,299
Gross revenue ...	£315,206 ...	£459,119 ...	£143,913

THE POST OFFICE VOLUNTEERS.—An inspection was held on Friday, May 23rd, at the Charterhouse, where the Manchester, Birmingham, Edinburgh, Glasgow, and Hull detachments Field Telegraph Corps and 24th Middlesex (Post Office) Rifles were formed in full marching order. There were between 130 and 140 of the enrolled telegraphists in the London Central Telegraph Office, besides the contingents from the provinces, on parade. Colonel Du Plat Taylor having made a close inspection, congratulated the men on their appearance, and gave them some practical words of advice. At the close the column, under Sergeant-major Flanagan, marched to head-quarters, where later on those who had volunteered for the Army Field Telegraph Corps were finally examined and enlisted. It will be remembered that some time since the War Office authorised the enlisting of 100 men of this corps into an Army Field Telegraph Corps, fifty for active service and fifty for a reserve.

ELECTRIC LIGHTING IN AUSTRALASIA.—News has just been received that the contract has been let for lighting the magnificent Parliament Houses in Melbourne with electric lights. The contract has been given to the Australian Electric Light Company, with whom the Australasian Company have recently amalgamated their Victorian interests. The installation will provide dynamo power for 1,350 lamps, but probably only 1,000 will be needed at one time. In connection with this the Australasian Company have ordered two Victoria dynamos from the Anglo-American Brush Company. The lamps to be used are Swan lamps. The Australian Company has likewise secured the lighting of the General Post Office at Melbourne. A fine display of electric lighting has just been made at the Victorian Inter-Colonial Exhibition, electric lamps solely being used. A similar installation on a smaller scale was made at the recent Exhibition at Christchurch, in New Zealand, where during the whole period it was open the building was entirely dependent on the electric light.

BLASTING IN CONTINENTAL COLLIERIES.—In the course of an article in the *Colliery Guardian* for May 23 Mr. G. G. André writes as follows:—"The system of exploding a number of shots simultaneously in rock blasting is making its way slowly into common use. It is surprising that a system offering so many advantages should need so much advocacy. Some portion of the prejudice against it is no doubt due to past failures. But the obvious certainty obtained by using powerful currents and the ease with which such currents may be applied when the works are lighted by electricity should be sufficient to induce the disappointed to try again. A good example of the application of the lighting current to the ignition of blasts, and, I believe, the first of its kind, has just come under my notice in Germany. The mine is a colliery, and the surface works are lighted by arc lamps. Underground a stone drift is being driven, and this drift is lighted by incandescent lamps. In the face from twenty to twenty-four shots are placed, and an electric fuse in each is joined up in parallel circuit by means of bare iron wire and connected with the lighting cables in such a way that the current can be shunted from the lamps into the fuses. The result is in the highest degree satisfactory. Misfires are unknown, and the effect is wonderfully good. It is estimated that from twenty-eight to thirty-two shots would be needed if fired in the usual manner in succession; so that the saving of labour is in this case considerable, exceeding 25 per cent., both for the labour of boring and the quantity of explosive required."

THE INSTITUTE OF PATENT AGENTS.—The second annual meeting of the members of this Institute was held on Wednesday at 55 and 56, Chancery-lane. The annual report of the Council stated that since the end of the first financial year, which terminated on April 30, 1883, nineteen new members had been elected. The Institute now comprised fifty-four fellows, two associates, thirty foreign members, and three graduates. During the twelve months that ended on April 30, 1884, the Institute held nine meetings, at six of which papers of interest to patent agents were read. The Institute had been already established on a firm and broad basis, when the whole subject of the laws relating to patents, designs, and trade marks was brought before the House of Commons by a Government Bill presented by the President of the Board of Trade. The Institute had taken an important part in the legislative changes which, by the passing of the Bill in a modified form, became law on the first day of the present year. Other subjects of importance connected with the working of the new Act and Rules, and with the action of the Patent Office, have been dealt with by the Council during the past financial year. The Council congratulated the members on the fact that the Institute has now attained a position which has met with full recognition from the Board of Trade and from the officials engaged in the administration of the Patent Law. With the Board of Trade and the Patent Office the relations of the Council have from the first been of the most satisfactory character, and notwithstanding that the Institute has not yet been in existence for two years, its representations and suggestions have met with a recognition which augurs most favourably for its future career of usefulness. On these grounds the Council now feel justified in inviting the co-operation, as associates, of both classes of members of the legal profession, as well as of engineers, manufacturers, chemists, and others interested in the Patent Laws, and generally in the protection of inventions.

A PHOTOMETRIC STANDARD.—Speaking of M. Violle's standard of light, which has just been adopted by the Electrical Congress held at Paris, and which he states to be the "radiation emitted by a surface of one square centimetre of platinum at its point of solidification," the *Journal of Gas Lighting* remarks: "It is to be accepted, upon M. Violle's authority, that the principle of his standard is correct; and that fused platinum, upon the point of solidifying, will always give the same light during a period convenient for photometrical measurements. This is really all that he has to say on behalf of the standard; for all the other desirable conditions of cheapness, handiness, portability, and facility of reproduc-

Digitized by Google

tion, wherever a test may be required, are absent. It must be said that the circumstances amid which the new unit has been devised and accepted are not so satisfactory as they might have been. M. Violle is probably a trustworthy experimentalist; but, all the same, it might have been wished that some independent authority had been entrusted with the tests of his suggested unit. It is scarcely necessary to cite examples to show how the mere suspicion of bias on the part of an experimentalist has vitiated the results of his observations. Here there is every reason to suspect the existence of such prejudice as an inventor naturally entertains for the fruit of his creative brain; and consequently all that he says in favour of the platinum standard will be taken with a great deal of "salt." Briefly, the whole thing has too much the air of being made to order, and taken on trust by the people for whom it was prepared. It is as much a private proprietary article of M. Violle's as though he had patented it; and something more is wanted for the warranty of what is ambitiously styled an absolute unit of light. It remains to be seen whether other photometrists will share M. Violle's admiration of melted platinum. It will be useful to note that, assuming the Carcel lamp to be equal to 9·5 English standard candles, the value of the platinum standard is 19·665 candles; and it is consequently the most powerful unit yet proposed."

American Institute of Electrical Engineers.—Dr. Norvin Green has been elected the first president of this Institute. The first vice-presidents are A. Graham Bell, Charles D. Cross, Thomas A Edison, Geo. A. Hamilton, Charles H. Haskins, and Frank L. Pope. The following gentlemen have been elected managers—viz., Charles F. Brush, William H. Eckert, Stephen D. Field, Elisha Gray, Edwin J. Houston, C. L. Hillings, Frank W. Jones, George B. Prescott, W. W. Smith, W. P. Trowbridge, Theodore N. Vail, and Edward Weston. Mr. Rowland R. Hazard is to be treasurer, and Mr. Nathaniel S. Keith secretary. According to the rules adopted at a meeting held on the 13th inst., the Institute is to consist of members, honorary members, and associates. Members and honorary members must be professional electricians and electrical engineers. Associates are to include persons practically engaged in electrical enterprises, and all suitable persons desirous of being connected with the Institute. Each person desirous of becoming a member or associate must be proposed by at least three members or associates, canvassed by the Council and elected by a majority of the members and associates as expressed by letter ballot to a regular meeting of the Council. The entrance fee is five dollars for each person, and both are to pay an annual subscription of ten dollars per annum. The affairs of the Institute are to be managed by a Council consisting of a president, six vice-presidents, twelve managers, a treasurer, and a secretary. The meeting resolved to appoint a committee of three to take such action as they might deem proper with a view to calling the special attention of Congress to the needs of the Patent Office, as it appeared from a letter communicated to the Institute that the office was so shorthanded that applications for patents would have to wait four months before they could be examined, the examiner being 600 cases behindhand. This, be it noted, is not because the Patent Office is a costly institution, and takes money out of the Treasury chest, for it appears that last year the office made a profit of 471,000 dols.

The Electric Railway at Brighton.—We have from time to time referred to the electric railway which has been constructed at Brighton, through the energy of Mr. Magnus Volk of that town. As our readers may remember, the line is about a mile in length, extending from the Aquarium to Kemp Town, passing under the Chain Pier, which necessitates some heavy gradients, as follow:—

1 in 100	230 yards long.
1 ,, 45	100 ,, ,,
1 ,, 16	50 ,, ,,
1 ,, 30	50 ,, ,,
1 ,, 150	200 ,, ,,

The remainder is practically level. The rails are 20lb. flange and are laid on creosoted sleepers. The current is generated by a Siemens D² machine, driven by a Crossley 8-horse-power gas-engine, consuming about 1,600 cubic feet per day of 11 hours. The cars are driven by a Siemens D² motor (old form), and run at a speed of eight miles per hour. They are fitted with an internal geared pulley, which revolves at the same speed as the axle on the level and all the gradients except the 1 in 16, when by means of a clutch the gearing comes into action and trebles the power applied to the axle, and causes a corresponding decrease of speed. The brake-power of the motor on the level is about 1¾ horse-power. The financial results are most encouraging, the result of the last eight weeks being, acccording to figures which we have every reason to believe are perfectly reliable, as follows:—

Number of passengers, 34,000. Gross earnings, £278 14s. 3d.

Earnings per week, say	£34 15 0
Expenses as enumerated below	17 19 0
Balance	16 16 0

Weekly Expenses.

Driver	£1 4 0	
Conductor	1 4 0	
Station clerk	1 4 0	
Station clerk (female)	0 6 0	
Lineman	1 1 0	
Labourer	0 18 0	
Engine-driver lad	0 12 0	
Electrical and general management	3 10 0	
		£9 19 0
Rent of arch		0 10 0
Repairs, say		1 0 0
Cost of gas at 3s. 3d. per 1,000		1 10 0
Depreciation and interest on £2,500		5 0 0
		17 19 0

The above result has been obtained with one car running about 82 miles per day—say 500 miles weekly, and seating 30 passengers. Two cars will shortly be running, a turn-out being provided half way. The expenses of the second car should not add very greatly to the total cost of working, whilst of course the running capacity of the line will be doubled. We think Mr. Volk is to be congratulated most heartily on the success which has crowned his efforts.

Telephone Exchange Licences.—In the House of Commons on Thursday, the 22nd inst., in reply to Mr. Gray, Mr. Fawcett said:—The number of applications for telephone exchange licences since the institution of the new conditions requiring each company receiving a licence to undertake to sell instruments to the Postmaster-General had been 77, and the number granted had been eight. The new condition was inposed solely for the purpose of protecting the public, and was not intended to check the establishment of telephone exchanges. He had been for some time considering whether with due regard to the public interest it could be in any way modified. As soon as he was in a position to come to a decision on the point, there would be no delay in making it known.—Mr. Gray moved to reduce the vote by the sum of £15,566, being the amount received by the Post Office for royalties from telephone companies during 1883. The hon. member explained the working of the present law relating to telephonic communication, and contended that it was grossly unfair that the royalties to which he objected should be exacted, the Government having attempted to strike at the use of telephonic com-

Digitized by Google

munication not in a direct way but by means of a side issue. A few years ago the Postmaster-General granted licences on the mere condition that a royalty of 10 per cent. should be paid. Suddenly he changed his policy, and said he would grant no licences unless the companies who applied for them should sell him as many instruments as he wanted to be used by him for any purpose he thought fit. But neither the parent company nor the subsidiary companies had power to do that, because if they did they would have violated their contracts, and the Postmaster-General knew that very well, for he had in black and white the terms of the contracts between the parent and the subsidiary companies. The policy of strangulation was adopted about two years ago, and not only had remonstrances been made by the companies, but deputations from the various towns waited upon the right hon. gentleman in vain. The people of Plymouth did not understand why they should be refused facilities granted to Manchester, or the people of Cork why they should be refused facilities granted to Dublin. The right hon. gentleman, however, said that the towns which had been left out in the cold should be served by the Post Office or not at all. That was a position which the Postmaster-General would find to be untenable, because the public would not tolerate it. The principle upon which Parliament gave a monopoly to the Post Office was that there should be uniformity throughout the United Kingdom. While the Post Office had been working the telephone during the last two years they had only got 700 subscribers at their various telephone exchanges. For those 700 subscribers they had 5,000 telephone instruments, and so far were they from being apprehensive of the supply of instruments running short that they had been selling them at a profit, and, further, the Post Office, by a contract entered into with the United Telephone Company, had a right to a supply of 15,000 more—that was to say, they had under their control 20,000 instruments in all. That was not protecting the public but destroying the profits of the telephone companies, which earned those profits by making instruments and selling the use of them to subscribers. The action of the Post Office in connection with trunk lines was such as could not be approved. The conditions imposed by the department upon companies who wished to place different towns in telephonic communication by trunk lines, among which conditions was one to the effect that customers must be charged at a rate of 10s. per mile, were so exacting that subscribers could not be obtained, and the public were consequently deprived of the facilities for communications which they ought to have. It had been said that talking stations could be opened in London from which conversations could be held with subscribers at a charge of a 1d. The authorities, however, had refused to countenance the proposal, and the Postmaster-General had said that it could not be entertained even experimentally. The general policy of the Post Office seemed to be to prevent the public from receiving the advantage of telephones, of which the department had less than 400 in the whole of the United Kingdom. He did not intend to bring forward any specific vote, but he appealed to the right hon. gentleman, whose administration at the Post Office had been distinguished in many ways by liberality, to extend that policy of liberality to the telephone question and not to punish the public, because, under a purely technical judgment, he had obtained the right of control.—Mr. Fawcett remarked that some very strong things had been said about the department by the hon. member for Carlow, but he should much regret if any word he said in reply was in any way taken to separate himself from the permanent officials of the department. He alone was responsible for everything that was done. All sorts of charges were brought against the officers of the department as if they had some private motive to serve, but they had no interest except the interest of the Post Office and of the public. It was urged upon him that he should not deal harshly with the telephone exchange companies, and that he should not act on the supposition that they had been consciously acting illegally, and in the exercise of his full legal rights confiscate their property. He was urged to deal in a generous and liberal spirit with them. He had done so. He assumed that the telephone exchanges had been established *bonâ fide*, and he entered into an arrangement that enabled them to continue their business. Consequently in all those towns in which at the time of the decision telephone exchanges were established a licence was granted to them on certain conditions which were agreed to between the companies and himself. The hon. member for Carlow had again and again repeated that he had been actuated by a desire to strangle the telephone companies. Nothing was further from his desire than to do anything unfair towards them. He had had to administer a monopoly, not which the Post Office had bought, for the Post Office had no money, but which had been bought with 10 millions sterling of money of the taxpayers, and he was bound to see that that large expenditure was guarded with adequate precautions. He was a trustee. Suppose a commercial man bought an invention for £100,000, and that he appointed a manager to administer it. Suppose that another patent was taken out for an invention which the courts of law declared to be an infringement. Now, in allowing other people to use that patent, which was an infringement of the one which had been purchased for £100,000, he would refer it to the hon. member whether a manager would not be faithless and not properly careful of his trust if he did not see that the use of the second patent should only take place under conditions which would be adequate to properly safeguard the interests of the first one. That was exactly his position. He was nothing more than a trustee. He was free to confess, as he had stated to the hon. member in the afternoon, that it had been shown by experience that the new condition which he thought it had been necessary in the interests of the public to impose two years ago had checked the development of private telephonic enterprise. He had not intended that this should be its effect; but having ascertained that this was its result, he had been considering for some months—it was a question beset with difficulties and complications—whether he could modify the condition in such a way as to get over the difficulty, while at the same time the interests of the public were properly safeguarded. He could only say that he was willing to repeat that promise.—Mr. Gray thanked the right hon. gentleman for his courteous reply. He had stated that he was bound to protect the public revenue; but he was amazed that no reference had been made by the right hon. gentleman to the deliberate expression of opinion by Parliament in 1878 on this subject. As far as Parliament was concerned, it expressed its desire that the department should not control the telephones. It was to be hoped that the right hon. gentleman would see his way to announce his decision within some reasonably short space of time.—Mr. Fawcett promised that, as far as he was concerned, there should be no unnecessary delay in coming to a decision. The particular point which, he said, had been for some time past engaging and still engaged his attention was the clause in the Telephone Exchange licences which gave the Post Office a general user of the telephones. But what he had said on that point would not apply to the subject of trunk wires, because that question had, as he understood, been settled for the present at any rate. The motion was then withdrawn.

THE INDUCTION OF CURRENTS IN CORES.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 606, VOL. XII.)

Example 1.—Now let the coil wire and the core be of copper, $\rho = \rho_1 = 1{,}700$, and $\mu = 1$, and take $c_1 = 1$, which is near enough. Also let the core fill the coil opening, making $a = c$, and let this be 1 cm., and the depth $b = 2$ cm. Then

$$w/W = \pi \,.\, 100v^2/1700^2 = v^2/9{,}000 \text{ say.}$$

Thus, by the approximate formula it would require a speed of 95 waves per second to make the core and coil heats equal. This value of the speed, however, with the other data, makes y too large for Y to be altogether left out, and the core heat is really about $\frac{3}{5}$ of the coil heat.

Example 2.—With the same dimensions, let the core be of iron, with $\mu = 100$ and $\rho = 10{,}000$. Here $x = 8v/10$ and $y = 64v^2/100$. We find, by (37), $w/W = \pi v^2/17$. Therefore to get equal heats the approximate formula makes v as low as $(17/\pi)^{\frac{1}{2}} = 2{\cdot}32$ waves per second.

Example 3.—The same iron core, but with $v = 100$ per second. Here the approximate formula makes $w/W = 1848$. But now y is so large that Y must be considered. Its value works out Y = about $\frac{1}{70}$. Consequently $w/W = 1848/70 = 26{\cdot}4$, *i.e.*, 26·4 times as much heat in the core as in the coil. Increasing the size of the core also increases the ratio, with a corresponding increase in the size of the coil. In this last example put $\mu = 1$, *i.e.*, core non-magnetic, but with the same conductivity, then $w/W = \pi/17$ only.

Some remarks need be made concerning the heating of iron cores. In the first place, although the induction may be 100 or more times the magnetic force when the latter is weak, yet the ratio will get smaller and smaller as the force increases. Hence, as in the above calculations μ is treated as a constant, the results are only strictly applicable when the range of the oscillatory current is not so great as, by the magnetisation set up, to alter μ much. Should μ be much altered the strength of the induced current, and the consequent heating, will be correspondingly lowered.

Again, suppose that the oscillatory current in the coil circuit is not the only current there, but consists of variations in the strength of a current of continuous sign. Here evidently the permanent current, by the permanent magnetisation it produces, lowers the value of μ, and the proper value as thus lowered must be taken in the above formulæ. In the extreme, when the permanent current is so strong as to practically saturate the iron, or produce nearly the greatest magnetisation it can legitimately receive under the circumstances, *i.e.*, without mechanical shocks to make the molecules settle into a state indicating a much greater magnetisation under the influence of the magnetising current than it would take unaided, then, unless the oscillatory current is so strong as to undo the work of the permanent current, the changes in the induction will be comparatively small. Let the oscillatory current be a small fraction of the permanent, then μ must be little greater than unity, so far as the variable magnetic force is concerned, and the induced currents and the heating little more than they would be in a non-magnetic core of the same conductivity, *i.e.*, considerably weaker than in a similar copper core.

Professor Hughes says he has discovered that air has a maximum capacity for magnetisation, and that it is equal to that of the purest soft iron. Here evidently, since for μ to be 100 or 50, or whatever it may be, is absurd, the undefined term capacity is used, so far as it is applied to air, to indicate something very different from μ the magnetic permeability. Nor can it be κ, the ratio of the magnetisation to the magnetising force. As the question is one of considerable importance it is to be hoped that Professor Hughes's researches will cast much light upon this and many other little understood parts of magnetic science. In the meantime we may here briefly point out one or two things in connection with saturation and conclusions from the mathematical theory. Let there be a coil, or long slender solenoid for simplicity, containing an iron core, and let a steady current be passing through the wire. The iron becoming magnetised, the action on a magnetic needle outside is increased above what it would be if the core were absent. Increase the current sufficiently, and the iron is said to become saturated, no further increase of magnetisation taking place. This is represented in the theory by supposing the value of μ to fall to unity. If this is practically reached, the core will then, so far as further increase of current goes, behave as if it were replaced by air. The action upon a needle at a distance should still go on increasing, and in proportion to the increase of current above the saturating value. But should the action on the needle stop increasing, or show signs of tending to a limit, not increasing as the current, the conclusion that the magnetisation of the core remains constant is erroneous. It must be decreasing. For our supposed observation shows that the magnetic induction tends to a limit, or at any rate does not increase as it should with $\mu = 1$. Every tube of induction goes through the core (with a correction for the space occupied by the coil), and in the core the induction is the resultant of the magnetic force and of 4π times the intensity of magnetisation, whilst the magnetic force is that due to the current in the coil by the ordinary formula plus the polar force of the magnetisation, which latter may be practically confined to the ends by lengthening the coil. The magnetic force then increasing in the same ratio as the current, and the induction in the air outside by our supposition not showing corresponding increase, the magnetisation of the core must be decreasing, or μ must have fallen below unity in the iron.

It is also obviously suggested that, the iron being removed, the mechanical force on a magnet outside, say on a needle at a sufficient distance to keep its magnetisation constant, may not continue to be proportional to the strength of current when the current is very strong. In this case, keeping to the relation $4\pi\gamma = \text{curl H}$ between the current and the magnetic force, μ also becomes less than unity in the places of strongest force. And as we conclude from the behaviour of, say, copper in a strong field of force that the permeability of the copper is less by a trifle than that of the air enveloping it, if we have μ less than unity in the air it must be still more less than unity in the copper, and probably less than unity in vacuum also with a sufficiently strong current.

The published dynamo formulæ giving relations between the current strength and the E.M.F. are very much alike in this, that if you take away the iron they break down immediately. It is the fact of the magnetisation of iron not being proportional to the strength of current that is made use of to put a stop to the increase of the current when the speed is kept constant. But if μ falls in value in air or vacuum also, it will make the same or similar formulæ applicable to dynamos without any iron, in which present theory indicates indefinite increase of current when the speed is the least above a certain critical value, and the speed is kept constant, with therefore an indefinite supply of power. But we must return to the main subject from these parenthetical speculations.

Coil Current in Terms of E.M.F.—We require to know to what extent the current in the coil is altered by the presence of the conducting core, *i.e.* given the impressed force E sin nt, required Γ in terms of E. We have the equation of E.M.F. in the coil

$$E = R\Gamma + (L - L_1)\dot{\Gamma} + \frac{L_1\rho}{2\pi\mu c}\Gamma' \quad . \quad . \quad . \quad . \quad . \quad . \quad (19)\,bis,$$

where, by (15), $4\pi N\Gamma = H_c$, the boundary value of H, and by equation (25)

$$H = (AM + BN)\sin nt + (AN - BM)\cos nt \,. \quad (25)\,bis.$$

Putting Γ in terms of H in equation (19) we get the two equations

$$\left.\begin{aligned} 4\pi NE &= AP + BQ \\ 0 &= AQ - BP \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (38)$$

in which the new quantities P and Q are given by

$$\left.\begin{aligned} P &= RM - (L - L_1)\,nN + \frac{\rho L_1}{2\pi\mu c}M' \\ Q &= RN + (L - L_1)\,nM + \frac{\rho L_1}{2\pi\mu c}N' \end{aligned}\right\} \quad . \quad . \quad . \quad (39)$$

From (38) we obtain

$$\left.\begin{aligned} &(4\pi NE)^2 = (A^2 + B^2)(P^2 + Q^2) \\ &A = 4\pi N\frac{EP}{P^2 + Q^2} \qquad B = 4\pi N\frac{EQ}{P^2 + Q^2} \end{aligned}\right\} \quad . \quad (40)$$

Digitized by Google

A and B being thus known, the current and the magnetic force in the core and the coil current become known at every moment. In equation (29) put for A^2+B^2 its value given by the first of equations (40), and we get

$$(\Gamma)^2 = E^2 \frac{M^2+N^2}{P^2+Q^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (41)$$

giving the amplitude of the coil current in terms of E and known functions, in which r is to be put $=c$.

The current at the time t is

$$\left.\begin{array}{l} \Gamma = (\Gamma) \,.\, \sin(nt-\epsilon) \\ \tan\epsilon = \dfrac{QM-PN}{QN+PM} \end{array}\right\} (r=c) \quad . \quad . \quad . \quad . \quad . \quad (42)$$

where

The angle ϵ determines the difference of phase between the current and the E.M.F.

The full expression for P^2+Q^2 is by (38),

$$P^2+Q^2 = \{R^2+(L-L_1)^2n^2\}(M^2+N^2) + \left(\frac{\rho L_1}{2\pi\mu c}\right)^2(M'^2+N'^2)$$
$$+ \frac{R\rho L_1}{\pi c\mu}(MM'+NN') + \frac{\rho L_1}{\pi c\mu}(L-L_1)n(MN'-NM') \quad . \quad (43)$$

where, besides M^2+N^2 and $MM'+NN'$, for which the expansions have been given, equations (30) and (35), there are two other functions. If many terms are required we may derive the expansions of $M'^2+N'^2$ and $MN'-NM'$ from M^2+N^2 by differentiations. For we have

$$2(M'^2+N'^2) = \frac{1}{r}\frac{d}{dr}\,r\,\frac{d}{dr}(M^2+N^2),$$

as may be proved by equations (26). And

$$MN'-NM' = \frac{1}{2xr^2}\frac{d'}{dr}r^2(M'^2+N'^2),$$

as may also be proved by equation (26). We thus find

$$M'^2+N'^2 = \frac{x^2r^2}{4}\left(1+\frac{3y}{4^26^2}+\frac{10y^2}{4^2\ldots10^2}+\frac{35y^3}{4^2\ldots14^2} + \frac{126y^4}{4^2\ldots18^2}+\ldots\right) \quad . \quad . \quad . \quad . \quad (44)$$

$$MN'-M'N = \frac{xr}{2}\left(1+\frac{6y}{4^26^2}+\frac{30y^2}{4^2\ldots10^2}+\frac{140y^3}{4^2\ldots14^2} + \frac{630y^4}{4^2\ldots18^2}+\ldots\right) \quad . \quad . \quad . \quad . \quad (45)$$

It may, however, according to circumstances, be easier to calculate the values of P and Q separately from equations (39). Of course we must then find the values of M, N, M', and N' separately, the first two by equations (24) and the last two from the expressions obtained by differentiating them.

First Approximation to Effect of Core Currents in Altering Amplitude and Phase of Coil Current.—This we obtain by taking only the first terms of the different series, that is, we consider only the first power of $\frac{1}{\rho}$. How far this will approximate to the truth will depend on the size of y, as illustrated in previous examples. In equations (39) take

$$M=1, \quad N=\frac{xr^2}{2^2}=\frac{\pi\mu nc^2}{\rho}, \quad M'=-\frac{4x^2r^3}{2^24^2}=-\left(\frac{\pi\mu nc^2}{\rho}\right)^2\frac{1}{c},$$
$$N'=\frac{2xr}{2^2}=\frac{2\pi\mu nc}{\rho};$$

they then become

$$P = R - \left(L-\tfrac{1}{2}L_1\right)\frac{\pi\mu n^2c^2}{\rho}, \qquad Q = Ln + R\frac{\pi\mu nc^2}{\rho} \quad . \quad . \quad (46)$$

so that the solution (42) reduces to

$$\Gamma = \frac{E}{\left(R^2+L^2n^2+RL_1\dfrac{\pi\mu n^2c^2}{\rho}\right)^{\frac{1}{2}}}\sin(nt-\epsilon) \quad . \quad . \quad (47)$$

and

$$\tan\epsilon = \frac{Ln}{R+\frac{1}{2}L_1\dfrac{\pi\mu n^2c^2}{\rho}} \quad . \quad . \quad . \quad . \quad (48)$$

This solution (47) and (48) shows that when induction of currents is permitted the retardation of phase is reduced, whilst the amplitude is also reduced. Put $\rho=\infty$ and we have the solution for the case where there is the same core inside the coil, but, by proper division, the currents cannot flow. The reduction in the strength of the coil current from E/R to $E/(R^2+L^2n^2)^{\frac{1}{2}}$ is then due to the self induction, including that due to the magnetisation, and the retardation of phase is $\epsilon = \tan^{-1}\frac{Ln}{R}$. Now (47) and (48) show that, when the induced currents in the core are allowed to flow, and the speed is not so high, or the dimensions so great as to make it imperative to use more terms of the series, the effect on the amplitude and phase of the coil current is the same as if the resistance of the coil circuit were increased

$$\text{from R to } \left\{R^2+RL_1\frac{\pi\mu n^2c^2}{\rho}\right\}^{\frac{1}{2}} = R+\tfrac{1}{2}L_1\frac{\pi\mu n^2c^2}{\rho}$$

approximately, thus reducing the time constant, the strength of current, and the retardation of phase. Many phenomena which may be experimentally observed when rods are inserted in coils may be usefully explained in this manner.

(TO BE CONTINUED.)

OLD CABLE STORIES RETOLD.

BY F. C. WEBB.

THE FIRST CABLE CRUISES OF THE OLD "MONARCH."

In 1852 the Electric Telegraph Company had decided to lay cables from Orfordness to Scheveningen, in Holland, and a company was formed, styled "The International Telegraph Company." This company was practically a mere department of the older company, and the whole concern soon afterwards took the name of "The Electric and International Telegraph Company." Mr. E. Clark was engineer to both companies.

At that time only the Dover and Calais cable had been laid, and it was determined to lay four cables with single conductors instead of a heavy compound cable with four conductors, as not only the risk of loss during laying would be less, but the risk of total interruption when the cables were laid would be less. This proved eventually correct, for during the four years I had charge of the cables only once was there total interruption, and that only for a few hours, when during some operations I broke the last cable by accident at night, but repaired it at dawn of day; whereas, on the other hand, the Dover and Calais cable and Dover and Ostend cables were once broken by the same ship, and total interruption ensued for several weeks, the "Monarch," then with me at Holyhead, having to be chartered by the Submarine Telegraph Company, and brought round to Dover to execute the repairs. But the cables were no doubt too light for the locality, and have since been taken up. Compound cables were laid in their place, which have resulted in total interruption for months; and yet a new compound cable is now about to be laid by the Post Office in their new steamer the "Monarch."

The core for these four "Hague cables," as they were generally termed, was supplied direct to the company from the Gutta Percha Company in Wharf-road—now a part of the Telegraph Construction Company. The iron wire was supplied also direct to the company from Messrs. Tupper and Carr, and the contract for serving and sheathing was given to Messrs. R. S. Newall and Co., who had erected temporary works at the North Dock, Sunderland, where they were making the Ostend cable. All the core was taped, tarred, and sanded previous to its being handed to Messrs. Newall and Co. Most of this work was done by Mr. H. V. Physick, in London, but a part was done by the company, under my direction, with the company's machinery placed in Mr. Newall's works.

I was appointed by Mr. E. Clark to superintend the testing and watch the manufacture at Sunderland. I strongly recommended testing the cables, as manufactured, under water. This was agreed to, and I constructed a dock at Messrs. Newall's works for this purpose. The ground was pure sea-sand, so I determined on wood and concrete. The bottom was made of 9in. concrete, with a layer of tar, pitch, and sand about an inch thick over it. The sides were timber piles, planked and caulked and tarred. The shape was nearly square on plan, with one corner cut off. The dock held water per-

Digitized by Google

fectly, in spite of many prophecies to the contrary. The work was carried out by men on time work without any contractors, and only cost about £200.

The cables were manufactured two at a time, and coiled into the dock direct from the machines, the water being kept level with the top of the coils, which were oblong, with a row of piles between them to separate them. On Saturday nights the dock was pumped up full and extra tests taken on Sundays when the cables had been submerged for some hours. To get the water off I used a gutta percha pipe as a syphon over the quay into the harbour. Our tests were of course primitive, but still were more than had previously been taken. For insulation a deflection was taken on a horizontal galvanometer with certain battery power, the deflection with one cell on short circuit being also noted. We had no resistance coils in those days, but as I foresaw we should require some means of testing the distance of a fault I took the deflection on the galvanometer with the cable in circuit with one element as every ten miles was added to the circuit, and tabulated the results, and from these all the faults in the cables for four years were localised with sufficient accuracy for repairs.

These were the first cables tested in their entirety under water before shipment, and the process was not adopted again (except on the Irish cables made at Fenton's Works, Queen's Ferry, near Chester, where I constructed a brick and cement tank) until after the failure of the '58 Atlantic cable. All the welds in the iron wire of the Hague cables were galvanised, a galvanising tank being placed between the machines, and I believe these are the only cables on which this process has been carried out.

By the terms of the contract with Messrs. Newall, the Electric Telegraph Company were to find a ship, and Messrs. Newall to find men; but if I recollect right nothing was said in the contract, which was only on a sheet of note paper, about machinery. The price to be paid for the men was only £500. No payments depended on success in any way. The whole transaction, in fact, was quite different to anything done in the present day. When the two first cables were nearly ready it became necessary to look about for a ship. Lieut. (now Captain) Burstal, R.N., and I were deputed to look out for one. It was decided that a paddle was better adapted for the work than a screw, as when the ship is going slow, with the wind on the beam, the lee paddle helps to keep the ship up to the wind.

After visiting several ports we pitched on the "Monarch," a paddle-wheel steamer of about 500 tons, belonging to Messrs. Brownlow and Pearson, of Hull. The ship had holds less interfered with by beams than anything of the size we had been able to find. The price was £6,200, and to avoid the cost of bankers' commission the accountant of the Electric Telegraph Company was sent down to Hull with the money in notes. Being of a cautious disposition, Mr. Bennett had the notes sewn into the lining of his frock-coat. The next morning after his arrival we went to Messrs. Brownlow and Pearson. Mr. Pearson, who received us, had only one arm, and taking the notes in his only hand he crunched them up in a lump and thrust them into his trousers pocket as if they were so much waste paper, at the same time that Mr. Bennett gave a deep sigh of relief at the end of his responsibility.

I fitted up some machinery for paying out, and Mr. E. Clark and Mr. Robert Stephenson came down to see it. The brake consisted of two horizontal drums at the end of vertical shafts, with certain guides, and one drum could be shifted down suddenly, so as to disengage the cable entirely if necessary in case a kink came, which in those days were our bugbears. Mr. Stephenson did not express much opinion, except that all the places where the men had to stand should be cased in with light iron plating. Mr. Newall, however, claimed to use his own brake, and called mine rubbish, and eventually Mr. E. Clark telegraphed from York to me to remove my brake, saying afterwards to me verbally that it would be childish to dispute about a brake. So mine was removed, and Mr. Newall's placed instead, and I am bound to say that, looking back, Mr Newall's was the best, for mine was made in a great hurry, and the workmanship was not very good. On the other hand, in preparing the holds, of which there were two, I arranged them for paying out from the centre of the coils, which were oblong. But it was argued that the end of the coil was the proper place to pay out from, because that was what had been done before in the "William Hutt" screw steamer when laying the Ostend cable, which had just been laid. The beams I had taken out were replaced, and one at the end of the coils taken out. Further experience has since shown that the centre of the coil is the proper place to pay out from.

Mr. Newall's brake was a vertical drum brake, and with side place for strap on same drum. The drum was in one casting, and the spokes in a separate one secured to the drum by screws. There was a knife to fleet the cable, and a trough to lead the feed cable under it. It was, in fact, the father of the brakes used at the present day, and it always appears to me that Mr. Newall has never received sufficient credit for this design. I am not aware whether it could have been patented, because the knife for fleeting had been used for colliery ropes, but certainly the adoption of it for submarine cables was due to Mr. R. S. Newall.

There was no stern sheave as we have now, but about 10ft. inboard from the taffrail the cable passed over a roller and between two pulleys, and then played freely round the taffrail and side rails over curved castings fitted all round on the rails. This was my arrangement, and was intended to give the cable less power to tug at the stern when growing on the quarter when tide or wind is on the beam, and would tend to prevent the cable in these circumstances affecting the steering of the ship. The Port Patrick and Donaghadee cable had previously been lost by the ship swinging to the cable in a heavy lee-tide. As we know stern sheaves are now adopted, and the cables are so light and the ships so large that the brake-power applied to the cable does not affect the ship's steering much, even with a beam wind and tide. We had no picking-up gear in those days and only two buoys. These were intended to buoy the tag-ends of the shore ends, which, composed as they were of six separate cables and a central wire laid up together, would have three spare ends, even when the four cables were laid. There was no special testing room, and the "board-ship" testing appliances consisted of a vertical galvanometer in gimbals and a single-needle instrument for speaking to shore. When paying out we exchanged signals with shore every quarter of an hour on the single-needle instrument for continuity, and tested for insulation between times with our 288 elements. The deflection was 50° on starting, decreasing to 40° when the cable was all submerged.

It had been determined to lay two of the main cables direct from shore to shore, and lay the shore ends afterwards to save time, as our concession was nearly expiring and the shore ends were not ready.

Accordingly the ship was loaded with one cable, about 130 miles. The cable was coiled into the after-tank first, then back into the fore-tank, and then back into the main-tank, and then into fore-tank again. Thus the ship was never much out of trim when paying out.

We arrived in the "Monarch" off Orfordness on Sunday, May 29, '53, and found there H.M.S. "Adder," commanded by Captain Burstal, which had been specially lent by the Admiralty to assist us, and the "Goliath" tug, of London. Captain Burstal had previously marked the line out by flag buoys all the way across the North Sea from Orfordness to Scheveningen. These buoys were barrels with a mast through them, weighted by a pig of ballast, and carrying a staff and flag, and were the same as those used in the surveying service. They were placed about every ten miles. On board the "Monarch" were Mr. E. Clark, Mr. L. Clark, Mr. Foudrinier (the secretary to the Electric Telegraph Company), myself, and two clerks on the part of the company, and Mr. Spencer and Mr. Thomson on the part of Mr. Newall. Mr. Newall was to meet us at Orfordness, but had not arrived. Doctor (afterwards Sir William) O'Shaughnessy and Mr. H. Vernon Physick, who before had been assistant engineer to the Electric Telegraph Company, came on board, but not to accompany the expedition.

We anchored close to Orfordness, and ran a warp ashore, and waited patiently for Mr. Newall. The wind came on the land, and we buoyed and slipped the end of the hawser, and anchored in Hollesley Bay. On Monday we again anchored close to

Digitized by Google

shore. A consultation was held, and as our concession expired in three days if the cable was not laid by that time, Mr. E. Clark determined to proceed without Mr. Newall. We signalled the "Adder" and "Goliath" to get under way. At eight a.m. we had end ashore, and at nine we started. The "Goliath" had us in tow whilst we were weighing anchor, as we were close to the beach, and she continued towing for ten miles, when we cast her off. We left the "Adder" behind to bring off Mr. Thomson (Mr. Newall's engineer), and a clerk who had gone up the river for a sail. We kept some high trees on with Orfordness Lighthouse till lost sight of, which brought us to the first buoy; then we kept the buoy astern, bearing W.N.W., altering our own course so as to keep that bearing on until we sighted the next buoy, which we kept on an E.S.E. bearing, and so on throughout. I attended to the steering of the ship, and Mr. Sargent, a boatswain from the "Adder," attended to the signals from the "Adder," and assisted in steering when I was below. The "Adder" anchored at times, and took set and rate of tide and signalled to us, and she also kept ahead, and when she sighted a buoy placed herself on the line, and made a signal when she was on the bearing, so that sometimes we took her as a mark before we could see the next buoy. Thus the line was regularly ranged out in proper engineering fashion.

Mr. Thomson, as I have said, and one of the clerks not knowing we were going to start, had gone in a boat up the river Alde, and when we were some ten miles out a message came from the lighthouse saying, "Mr. Thomson is now coming down the river." Somebody repeated this on deck, and I recollect exclaiming, "How can you see them at this distance?" I had quite forgotten that we could speak to the shore or the shore to us, as this was my first experience of a message from shore to a ship under way at sea. I can well recollect the strange feeling it gave of novelty at the time. Soon after the "Adder" caught us up, and the clerk had a wigging from Mr. Foudrinier, ending with a "Go forward, sir," in true nautical style. Towards night it came on to blow, and soon increased to a gale from N.E. The tug bore up and ran for Harwich, and had a part of her paddle-box carried away. Mr. Newall had by the evening arrived at the lighthouse, and a series of messages passed between him and Mr. Clark. Mr. Newall told Mr. Clark that he was now responsible for anything that might happen, and Mr. E. Clark replied that the fact of Mr. Newall saying so would not alter the circumstances one way or the other. In the night the "Monarch" was rolling considerably, with a heavy beam sea on. Mr. Spencer had to be lashed near the brake, at which post he kept steadily throughout the work. Down below Mr. L. Clark attended to the testing, and when the rolling compelled a reclining position on the sofa, he had a string fast to the handle of the single needle, at which he tugged every quarter of an hour to give the continuity signal. One of the lanyards of the funnel stays got chafed through by the lifeboat rubbing against it, and the funnel was tottering at every roll. The captain, a very old man, rove a new one, at the peril of having his hand smashed. As the ship rolled to leeward and separated the boat by about four inches from the stay he quickly passed one turn, withdrawing his hand just in time before the next roll brought the boat back on the stay with a thud. I never saw so old a man, and not many young ones, do anything half so smartly. The changes of hold were managed well by Mr. Thomson and a foreman of Mr. Newall's, named Dingwell. In the morning the "Adder" was rolling till we could see her keel. We only missed one buoy in the night. At times, to keep our course when the cable in fore hold was all out, we had the helm hard down for an hour together. As we got near Scheveningen we got a little to the southward of the line, but nothing has been laid across the North Sea as straight as this cable. The distance is 114½ statute miles, and we only paid out 119½.

We anchored just at dusk a little to S.W. of Scheveningen. The next morning I was awoke by Mr. E. Clark coming down, laughing, and telling us all to come on deck, as "there were a lot of penguins alongside." On going on deck we found a Dutch schuyt rolling about at anchor near us, and four or five disconsolate people in oil-skins and sou'-westers sitting in a row on the boom. They were Mr. Ruysenhaars (the *concessionaire*) and some other gentlemen, who, with a zeal for the company's interest, had put off at night to board the expedition, had been unable to fetch us, and had passed a miserable night, without anything to eat, in this most uncomfortable and penguin-like position. We got a ham-bone, some bread and grog to them as soon as we could. I had not had much experience of catering for telegraph ships, and the ham-bone was all that remained; and I was chaffed for many days about that poor bone. We did not get the end ashore until the day after this, and in this work I passed a night rolling about in a schuyt.

The two next cables and shore ends were laid soon after. The fourth was not laid until a year afterwards. When paying out this cable on a dark night, rolling along before the wind and sea, a foul flake occurred. About two tons of cable came up in a great skein, and crashed down the iron saddle, supported about 10ft. high on four 6in. timber legs, just where I had been standing an instant before. A portion of the skein wound round the drum, and of course stopped it dead. The cable streamed out astern towards the horizon. I had a smart foreman with me named Windle (who was afterwards with the Telegraph Construction Company). He got the stray chain of the buoy on the cable, and we just had time to cut the cable with an axe close to the rolling hitch, and away flew the end. Another instant and the cable would have parted. Yet when we came back three weeks afterwards we found the end safe fast to the stray chain.

We had by this time fitted the "Monarch" with our own machinery, including the first single drum picking-up gear ever made. I had four years on and off in the old ship, repairing and altering the course of the cables. The three first cables were laid too close together, but the fourth I laid about ten miles away to the northward of the others. This cable I also took up once and relaid. The fishermen used to hook a cable, heave it up, and let it go again, but during this time they would drift over another, and thus the cables used to come up regularly laid up in places like a rope, and to disentangle them without breaking one of the working cables was the great problem, and it was often very complicated and tedious work. It was very different work to repairing a single cable free from all others. We did not dare to dredge with the ship near a working cable, and I have had many a night in boats being towed to windward by the ship. The tide, too, off Orfordness at springs often runs four knots, and the cables, when lifted on the bight, having been laid quite tight, would not, of course, bear the weight of the ship hanging at right angles to their course. The paddles had, therefore, to be kept going at times fully half speed. When working on such occasions with boats under the bows on a dark night this was always a dangerous job, as there was the chance of a boat drifting into the wheel. I am happy to say I never lost any men, but, soon after I left, one was thus crushed to death in the wheel, and a cable foreman was killed in the picking-up gear.

The old "Monarch," if she could not go fast—about seven and a half knots was her fastest, if I recollect right—could creak to perfection (she was a wooden ship, and twenty-three years old when we bought her). She used to begin with a deep groan below the deepest growl of a Lablache, or a Formes, and then slur up to a note an octave higher than the highest note of a Patti.

We were much bothered, too, by fishing vessels. Once, when re-laying the fourth cable, such a large and closely-packed fleet of fishing vessels were sighted right in our course that I was obliged to deviate the cable round them. At times, too, when steaming out to the buoys their flash lights would crop up under our bows, and as fast as the helm was over one way there was a yell and a light, and we had to put it over the other. We used in spite of all this to lose patent logs, and rarely came into port without finding pieces of nets in our wheels. They used, too, to unshackle our buoys, and then bring them in and claim salvage.

Once when anchored off Scheveningen, in the summer, I brought off from the shore to lunch on board M. Eugene Sue, the celebrated author of "The Wandering Jew." Mr. Maas,

Digitized by Google

the owner of the hotel, had introduced me to him, and had told me before I saw him that he answered exactly his own description of his Wandering Jew, as his eyebrows met over the nose. This I found was the case. When coming off in the boat I asked him, amongst other things, if he had read any of Charles Dickens's works, "Oui," he said, "mais je préfère le Sire Valter Scott," which was to me a curious comparison.

It must not be supposed that the "Monarch" was solely engaged on the Hague cables. Two cables from Holyhead to Howth were laid from her and several times repaired. The Firth of Forth and Tay cables we also laid from her, but it would make this article too long to describe any of the work.

During the four years I gradually organised the system of buoys, mushroom anchors, bridles, grapnels, &c., which, with the picking up gear and brake, caused the "Monarch" to be the first ship regularly equipped for cable repairing, and she may consequently be fairly considered the father of the fleet of repairing steamers, amounting to some twenty-five, at the present day.

When I quitted the Company in 1857 I left the four Hague cables all in working order after some heavy repairing work. I telegraphed through from Orfordness to Mr. Weaver at Amsterdam the fact that the last repairs were completed, and I recollect for his reply he sent the words from the last duet in "La Favorite"—"*Va dans une autre patrie cacher ton bonheur.*" Those were the last words I received through the Hague cables, and ended my connection with the cable cruises of the "Old Monarch."*

* Three water colour drawings by me, one representing the old ship laying the first Hague cable in a gale; the second representing her picking up a cable with another crossing it, or what we called "coming to a crossing," and the third representing our boats dredging, hung for many years in the board room of the Electric and International Company. A sketch by me of the "Monarch" paying out in the gale appeared in the *Illustrated London News* in June, 1853.

CORRESPONDENCE.

INCANDESCENCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As the heat intensity or temperature of a flame of a sperm candle or paraffin lamp is practically constant, these form easily reproducible standards with which to compare the temperatures of lamps.

The great difficulty of getting photographic plates of a constant sensitiveness for any special part of the spectrum would, I think, prevent them being used in the manner suggested by "A. D.," on page 591, for temperature comparison.

If your correspondent will turn to page 409, Vol. VIII., of this paper he will there see the spectroscopic photometer we use at Brighton to compare the intensity of differently-coloured lights and their temperatures. In case he should not have access to the number referred to I give the following particulars of the instrument. It consists of a pocket spectroscope of considerable dispersive power (with a scale preferred), having in front of the slit two white planes at right angles to each other, and placed at an angle of 45° to the axis of spectroscope; or, instead of white planes, the ordinary reflecting prism may be used. The planes or prism are placed in a line between the two lights to be compared, so that on looking through the spectroscope two spectra are seen side by side, one belonging to each lamp. These spectra are of course perfectly continuous, *i.e.*, are free from bright lines or spaces because of the light proceeding from solid particles and not gases.

When it is required to compare the temperatures of lamps of the same or different candle-power, each one is first compared to a standard paraffin lamp for future reference, and from this the ratio of one to another is deduced.

The method generally adopted is as follows:—The photometer being placed between the standard lamp A and the incandescent lamp B to be measured, A is moved to or from the photometer until the yellow parts of the two spectra, corresponding to the sodium line D, match each other in intensity. The standard lamp is then fixed in that position, and the distance of B from the photometer is measured and noted. B is now moved to or from the photometer until the blue parts of the spectra corresponding to either the F line of the solar spectrum or the blue strontium line match. The new distance of B is then measured, and the inverse ratio of the squares of these two distances is taken to represent the ratio of the temperatures of A and B. The second lamp C is measured, and the two ratios are compared.

If the spectroscope has a scale the position of the particular blue part of the spectrum to be used for temperature comparison can be definitely fixed, but where there is no scale a pinch of salt in the standard lamp's flame will give the yellow sodium lines, and therefore the part to be used for light comparisons, and a little chloride of strontium the blue line for that for temperature comparison. Theoretically, of course, the above method may not be an absolutely exact one for finding the ratio of two different temperatures—this ratio probably not being exactly proportional to the intensity of the more refrangible part of the spectrum—but some other function (not quite so simple) of this ratio; however, for practical purposes it is sufficiently accurate, and where it is only required to ascertain whether one lamp's temperature is the same as another's it is absolutely exact if properly carried out.—Yours, &c., ARTHUR WRIGHT.

Brighton, May 22.

ARTIFICIAL LIGHT TABLES (COPYRIGHT).

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have so often had occasion to refer to diagrams bearing a striking resemblance to those shown on page 38 of last week's *Electrician* that I hope there is nothing in the law of copyright to prevent me from using my own diagrams, now three years old nearly.

Besides the sunset, sunrise, lighting up and extinguishing curves I have found a "nine-hours' watch" line drawn parallel to (but two hours in front of and seven hours behind) the sunset curve very useful; and the diagram is made still more complete by the addition of the curves for street-lighting, which differ somewhat from those already alluded to, the lamps being kept alight 15¾ hours in winter, and only 5¼ hours at midsummer. The moonlight nights should also be made a note of.

I cannot say who was the first to introduce these corset-shaped figures, but they appear to have been known to the ancients.—Yours, &c., WM. H. MASSEY.

6, Westminster-chambers, London, S.W.

CENTRAL STATION LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In Horrebow's "History of Iceland" there is a chapter headed "Concerning Owls," which only tells us "there are no owls in this island."

In Mr. J. E. Gordon's recent treatise on Electric Lighting, reviewed in your last number, Chapter XIX. is upon "Central Station Lighting," regarding which it is stated, "I had intended to write a long chapter with the above heading, but for various reasons I am not yet prepared to do so."—Yours, &c.,

CAROLUS CLARUS.

ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been called to your reference to our use of accumulators at our Bristol station in your review of Mr. Gordon's book last week.

I have pleasure in informing you that we have found them in every way successful. They are of the Faure-Sellon-Volckmar type, and have been in constant use day and night for seven months. During that period they have never failed, and the total cost of renewals of plates has been less than one per

Digitized by Google

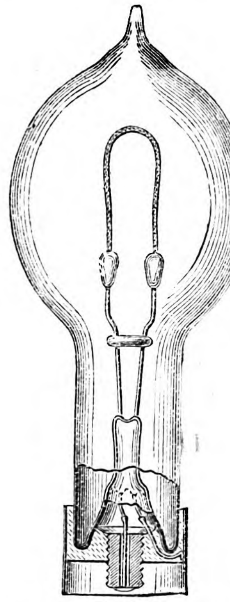
cent. on their cost. By their use we have saved very largely in wages, coal, oil, &c., besides being able to furnish our customers with a constant supply, the light being of course available at any time of the day or night. I may also mention that I have used accumulators in my own house for 21 months, and have found them thoroughly reliable. Indeed, so little attention do they require, that during the past six months the only thing done has been to fill them up with water in February last, to supply the evaporation that had taken place since November.—Yours, &c.,

J. B. Braithwaite, Jun., Chairman.

The Great Western Electric Light and Power Company,
4, Great Winchester-street-buildings, May 29, 1884.

THE BOSTON OR BERNSTEIN LAMP.

When gas superseded the candle and the oil lamp the economy realised consisted not so much in the cheapness of the light-giving material as in the concentration of light. One gas burner gave the light of 12–16 candles. It seems strange that this principle is so little mentioned with reference to incandescent electric lighting. The ordinary Edison or Swan lamp does not give more light than an ordinary gas burner,



The Bernstein or Boston Lamp.

and hence the greater expense of electric lighting. We all know that electric lighting is still in "*statu experimentis,*" but all the adverse criticism can be traced to one common source, namely, to the question of expense. Any improvement in this direction—any lamp which considerably diminishes the expense, if it also meets other requirements—must therefore be hailed with satisfaction, and such an improvement, it is claimed, was shown at the Vienna Electrical Exhibition of last autumn. Most of the incandescent lamps in use up to the present have a fine carbon thread of high resistance, which is brought to incandescence by the passage of the current. They have a comparatively small illuminating surface, and on an average gave a light of 16–20 candles.

The Boston lamp, invented by Mr. Alex. Bernstein, of Boston, Mass., gives a light of from 50–60 candles. A hollow carbon cylinder taking the place of the fine thread, and a larger illuminating surface, but with lower resistance, is hereby obtained. The external appearance of the lamp differs little from that of other lamps, only, as will be seen from the diagram, the carbon cylinder is not directly connected to the platinum wires, but by means of a special cement to two copper wires, which are soldered to the two ends of the platinum wires. The wires are kept in position by being fused into two pieces of enamel; a brass ring and a centre screw, each connected to one of the wires, are firmly attached by plaster of Paris to the lower extremity of the lamp. The brass ring and the central screw are fitted to a specially-constructed lamp holder.

The characteristic part of the lamp, the essence of the Bernstein patent, is made by carbonising a narrow and hollow ribbon of white silk.

The following are the measurements taken by the Scientific Commission of the Vienna Electrical Exhibition, under the presidency of Professor Dr. Kittler :—

ON SOME NEW PHENOMENA IN ELECTROLYSIS.*

BY G. GORE, LL.D., F.R.S.

Whilst making a series of experiments on the "self-deposition of metals" I observed by trying a number of different metals, that several of them received an electrolytic deposit of cadmium by contact with cadmium in various solutions of that metal much more frequently than others; I therefore made various experiments to determine whether this was due to difference of density of current or to other causes. By means of these additional trials I found by passing an undivided current simultaneously through a series of portions of the same metallic solution, that cathodes composed of different metals but of equal amounts of immersed surface, required currents of different degrees of density to cause deposits of the same metal upon them, and that the differences in some cases were considerable. Another singular circumstance was also observed, viz., that the cathode which most readily received a deposit was frequently the one composed of the same kind of metal as that which was being deposited. I am now examining these new facts.

DEFERRED TELEGRAMS.

Notwithstanding the Postmaster-General's declaration nearly four years ago that he would never sanction such a scheme as that of deferred telegrams, the Society of Arts has again lent itself to the discussion of the scheme, and several well-known agitators who have succeeded before now in imposing their wishes on the Government returned to the charge on Wednesday week with a great show of determination to succeed once again. We will not discuss the motives or the qualifications of these gentlemen, though both might be gravely questioned. Useful and practical suggestions deserve consideration, no matter from whence they may come, and as we are under none of the obligations to silence imposed upon the Post Office officials we will take up the challenge which Colonel Webber threw down to his former colleagues, and discuss the deferred telegram on its merits.

Briefly, what is meant by deferred telegrams considered from Colonel Webber's point of view is that, leaving the existing tariff pretty much as it is, except perhaps as regards free addresses—concerning which, however, the lecturer was not so explicit as he might have been—he would introduce a second class of messages at half price, to be forwarded, not in their turn as handed in by the senders, but only so soon as the full-priced traffic is disposed of. There is a pressure of traffic at certain hours, followed by slackness at other hours of the day, and all through the night, and Colonel Webber wishes to fill up these slack hours at a cheaper rate with messages which are not in such a hurry to be sent. He has discovered that at many offices, numerically the majority, the clerks do not do half an hour's telegraph work all the day long, and this is a picture of idleness which Colonel Webber apparently cannot bear to contemplate. Let the public send deferred messages at half price, and then the wires as well as the clerks would be fully employed. It is awkward for this contention that the class of offices here referred to is precisely that at which there is never any rush of work, where in fact work comes in by driblets and is as quickly disposed of as the facilities will permit. In point of importance this class of office is small, but it actually constitutes the bulk of the whole system, as a glance at any postal guide will show. Now, on such lines there would be practically no difference between a deferred and an ordinary message, except in the price paid for it, and the result would be simply an increase of unremunerative traffic. Some of Colonel Webber's supporters, speaking in the interests of the newspapers, were of opinion that to make an unprofitable business profitable you have only to increase it. This is the theory of the famous apple-woman who lost on every transaction but gained on the quantity. Mr. Saunders and Dr. Cameron may not have had this in mind, but the result held out was the same. It is not to be supposed that the Post Office authorities will invite the sending of messages merely to find occupation for their servants; nor, indeed, are the public likely to respond to such an invitation. If the deferred message is really deferred, the public will not be very anxious to spend sixpence on it when a penny letter would answer nearly as well. But the whole scheme is, we believe, based on a misapprehension. If we are not greatly mistaken, the duties of telegraphy and post office are performed by one and the same class of persons wherever the telegraph traffic is not sufficient to occupy the full time of the officer; and we know that in a vast number of the inferior offices the shopkeepers who have charge of the telegraph treat it as a mere incident of their business, not as a business by itself. The idle telegraph clerk is, we suspect, a creature of Colonel Webber's imagination. There are wires, and plenty of them, that are comparatively idle; but unless extensions are to be refused until there is traffic to fully occupy them this condition is unavoidable. Branch lines would not be filled with traffic even if it were transmitted for nothing. Here again there is a radical misconception. The general public only use the telegraph in urgency; indeed, the same may be said of the commercial public, the difference being only in the frequency of their urgent transactions. To encourage traffic of no urgency whatever, for the mere sake of filling the wires, is to forget the essential object with which all telegraphs are constructed, and to do it at a ruinous cost into the bargain. An idle wire costs nothing; to make use of it always costs something.

Again, as regards local traffic—the internal and suburban traffic of large towns—Colonel Webber supposes that by his

Digitized by Google

scheme of deferred telegrams this traffic would be greatly developed. We believe, on the contrary, that if persevered in the system would extinguish all local traffic by rendering it useless. In outlying districts, as we have already mentioned, the deferred message would have a good chance of travelling as fast as any other; but what chance would there be of a deferred town message running the blockade of traffic which it would be sure to meet on its passage from one part of the town to another part? Something may be said for a pneumatic system; but we may remind Colonel Webber that a pneumatic system is not a telegraph system—at its best it could only serve to connect large centres, and would leave the surrounding areas just as they are at present. The craze of people wholly bent on multiplying telegraph traffic is shown in nothing better than in this. The telegraph is an instrument of rapid communication between places widely apart. It is nothing if it is not that. Local telegraphy may occasionally be of some use, but in general it is a delusion; a messenger or a cab would serve as well or better; and as to the deferred telegram for local purposes, the penny post would beat it hollow.

Passing over Colonel Webber's assumption that the traffic of outlying districts, and indeed all traffic except the commercial, is of small importance and might be deferred; as also the manifest error of supposing that a slack period given up to deferred messages would not be used by commercial people for the sake of cheapness, till in course of time there would be no slack period available, and therefore no room for deferred traffic at all, there is only one other argument left to dispose of. It was shown even at the Society of Arts' discussion that no parallel could be drawn between the system of classified messages introduced in our colonial and Indian empires, and prevailing to some extent in the United States, where the distances are so great that the telegraph at its slowest may beat the post by several days at its quickest. But nobody noticed an equally serious mistake of the lecturer in confusing an accelerated message system with a deferred message system. They are in reality totally different. The one is a uniform low tariff, varied by a high express rate for special occasions; the other, Colonel Webber's plan, is a high uniform rate, with a lower one for messages that are not in a hurry. Something may be said for the first, though not much, when the bulk of the traffic is always urgent; but nothing at all can be said for the other, seeing that a deferred traffic on busy lines would suffer intolerable delay, whilst on slack lines the traffic would experience no appreciable relief by deferring a portion of it.

TUBULAR CARBONS FOR INCANDESCENT LAMPS.

BY M. A. BANDSEPT.

(Translation.)

At the present moment considerable interest is being bestowed in the financial world, and particularly amongst electricians, upon an invention which, although not altogether novel, appears destined to exercise a considerable influence upon electric lighting. Incandescence by electricity will certainly furnish the light of the future. Hitherto it has been unable to compete with gas from an economical point of view; but competition will commence in earnest the moment the cost of the new light has been materially reduced. Now, it would appear that the endeavours made to augment the duty of incandescent lamps have been attended with success, and an increase of some 80 per cent. is spoken of. And this important economic result is due to the use of hollow carbons for the production of the light in lieu of the solid filaments of this material ordinarily employed. The question of lighting by incandescence presents, therefore, a new point of interest in relation to the construction of the filaments, which affects in so marked a degree the industrial value of this mode of illumination.

It is understood that electric lighting is simply an application of the heat generated by electric currents, this heat being concentrated in the smallest possible space, so as to produce the greatest possible elevation of temperature. An electric current traversing a conductor raises the temperature of the latter more or less in proportion to the difficulty it encounters in its passage; friction here engenders heat. The temperature depends upon the resistance opposed to the current; and, if the friction is energetic, the heat produced may be considerable in the more attenuated portions of an electric circuit. The luminous intensity increases very rapidly with the temperature; for this reason a refractory body is employed in producing the incandescence.

The essential portion of an incandescent lamp is the carbon filament. It is necessary that the heat due to the passage of the electricity should be very intense, and that it should compensate for the loss of energy due to radiation from the filament.

The work due to the passage of the current is

$$W = E \times C = \frac{E^2}{R};$$

where E is the difference of the potentials at the extremities of the filament,
R the electric resistance,
and C the current.

The equation for work gives the further relation

$$R = \frac{E^2}{W} = \frac{W}{C^2},$$

in accordance with which the dimensions of the filament are determined.

The rule of working (*régime permanent*) of the lamp is given by the equation of equilibrium

$$s = EC = W,$$

in which s represents the radiating surface of the focus.

Let a represent the specific resistance of the carbonaceous filament, *i,e.*, the resistance between opposite surfaces of a cubic centimetre of the material; then the resistance of a cylindrical filament of the length l will be

$$R = \frac{4}{\pi d^2} + l + a$$

or $$W = dl, \text{ whence } l = \frac{W}{d}.$$

The formula given above thus becomes

$$R = \frac{4aW}{\pi d^3}.$$

Whence we have the values

(*a*) $$d^3 = \frac{4aW}{\pi R}$$

(*β*) $$l^3 = \frac{W^2 \pi R}{4a}$$

It is important in the first place to determine the effect of surface and of mass upon the radiating power of an incandescent filament. It is not sufficient to raise the temperature. What is of more importance is to preserve the heat supplied to the carbonaceous filament. Now, for equal masses, the lowering of the temperature is proportionate to the surface of the conductor. With fibres of small dimensions and circumference, the heat does not readily escape, but tends to become accumulated. The best form, from the point of view of the elevation and retention of temperatures, would be that of a sphere. Elongated filaments bent into horseshoe form are, however, generally used, for the luminous arc must have a certain extent of surface, and a certain volume of rays is requisite to produce a highly luminous effect. Intensity (*le titre élevé*) of light is not sufficient. It is only, however, when such

Digitized by Google

intensity is obtained that a favourable economic result is realised.

Thus the first principle in the working of incandescent lamps consists in raising the temperature of the carbon filament to as high a degree as the nature of such filament will allow.

This definition shows the importance that should be attached to the means of preserving the essential organ of the light when very thin filaments in which heat is concentrated are employed. The main cause of the destruction of electric carbons is to be found in the motion (*ébranlement*) which accompanies the passage of the current, and which occasions a kind of dissociation, of which the effects are naturally more pronounced as the resistance of the filaments is greater. The deterioration is partly due also to other causes, amongst which may be mentioned the electrolytic (?) action, which has the effect of weakening the filament at that portion where the current enters it.

With the view of conforming to the above-mentioned conditions and to the principle of the variation of the radiating intensity according to the extension of surface and of mass, recourse has been had to tubular carbons. This form allows us to realise an extended surface of incandescent carbon, together with a relatively small mass, and also to combine as far as possible the two opposite conditions of electrical and of mechanical resistance.

But, on the other hand, any great reduction of the mass and of the section has the drawback of diminishing to too great an extent the absolute quantity of heat brought into play, and which is advantageously stored in a latent condition, so as to regulate the irradiation. It became, therefore, necessary to employ, in conjunction with the attenuated filament of carbon, a fly-wheel—so to speak—of light, or, rather, of temperature, in which heat might be stored up and given out according to the variations in the supply. By adopting this means the data of the problem became sufficient, and a complete solution became possible. In fact, by employing as the organ for the light a filament formed of a central thread of refractory substance enveloped in a *thin* layer of carbon specially intended for the production of light, all the conditions necessary for high economical efficiency for the preservation of the filament and for the steadiness of the light were fulfilled. The tubular carbon seems therefore destined to contribute greatly to the much-sought-for solution of the question of economic incandescent electric lighting. Several inventors are occupied in making tubular filaments, and attention has been turned in this direction for several years already. What mention has been made of hollow carbons, however, does not relate to a process of condensing the caloric energy of the currents. The internal armature intended for the formation and preservation of the carbon more often played a completely different part to that assigned to it by theory. This armature should contribute to the accumulation of the heat of the current in the carbon, and should oppose all diffusion towards the interior of the tube. Sometimes it was made of metal, or recourse was had to a metal core covered with an insulating cover, which ended by disappearing, leaving a conducting layer on the interior of the carbon. Thus the first patent relating to filaments with an internal support is dated March, 1882. It mentions incidentally the manufacture of carbons in the form of filaments, by taking very fine metal wire covered with a thin layer of silicate of potash. The water in this layer is evaporated, then the wire is raised to a temperature high enough to separate the carburets of hydrogen or the chlorides of carbon so as to obtain a thick layer of carbon. The inventor adds that it is necessary to oppose the combination of metal wires and alkalies, and that the metal can be preserved in the carbon thus obtained. The last observation shows that it is no question in this case of applying the principle of caloric condensation otherwise than it is applied in solid carbons, since the heat is dissipated through the support or by the metallic layer which exists in the interior of the filaments when the central wire has been made to disappear. Again, whilst the tubular carbons and those furnished with a refractory core lead to an increase in the economy which recent experiments have made known, the process which we have just examined does not afford any increase in the economy of the lamps. It has indeed been found that for an intensity far superior to that generally emitted by incandescent lamps, we only obtain a light of less intensity than that given by the various filament lamps. This fact will be seen from an official report of the committee entrusted with the experiments carried out at the International Exhibition at Munich.

TABLE OF CONSTANTS.

	Maxim.	Edison.	Swan.	Siemens.	Cruto.
Ohm	47·01	139·60	31·91	104·72	8·16
Volt	65·07	103·05	38·38	95·74	22·15
Ampere	1·384	·755	1·222	·915	2·715
Horse-power...	·1224	·1057	·0637	·1191	·0817
Mean intensity	13·34	15·52	10·95	14·90	8·47
Candles per H.-P.	108·98	144·88	171·78	125·14	103·58

If, with these data before us, we compare the economy of the Cruto lamp—the carbon of which is made up by a deposit of dense hydro-carbon (C_4H_4) on a platinum wire, which is subsequently volatilised by the current—with that of Edison for instance, we find that the latter gives about twice the light for the same expenditure of energy. This result is explained by the small specific resistance of the filament of the Cruto lamp and by the loss of heat which occurs owing to metallising of the interior of the carbon.

The first patent which specially claims the use of the tubular form as a means of increasing the temperature of filaments through the accumulation of heat in the carbon is that of M. Somzée, and is dated December, 1882. Tubular filaments are obtained by applying under heat a layer of carbon to refractory wires. To make these wires, magnesia is highly calcined, and when worked up with a solution of acetate of magnesia is brought into the form of a plastic paste. This paste is compressed into a cylinder and drawn out in the shape of flexible wires. These are then subjected to a high temperature at the same time that carbonaceous particles are precipitated on them from dense hydro-carbons forced into refractory pipes. The divided carbon is thus incorporated by occlusion in the solid magnesia. The result obtained is an imperceptible layer of pure carbon adhering to the central refractory wire—that is to say, the electrical resistance most favourable to luminous economy, joined with preservation of the filament, and a mass sufficient to give a steady light. It is hardly possible to have a method which better fulfils the different conditions to be complied with.

The second invention relating to hollow carbons of weak section is that of Mr. Alexander Bernstein. It is known by the name of the Boston lamp. The inventor also proposes to obtain a large surface of carbon having a high resistance. He has accomplised this by curving into horseshoe form a tube of platted silk with thin sides. This tube, placed in a bed of graphite powder, is then carbonised in any convenient mode. Owing to the thinness of the sides the current experiences considerable resistance, and gives rise to an intense luminosity, due to the large surface in a state of incandescence.

Experiments made at the Vienna Exhibition assign to the Boston lamp a duty of 292 candles per electrical horse-power. If we compare this result with the figures obtained for the Maxim, Edison, and Swan lamps given in the preceding table, we find that as far as equality of light is concerned the Bernstein lamp is more economical by about 168 per cent. than the Maxim lamp, 100 per cent. more so than the Edison lamp, and 67 per cent. more than the Swan lamp.

It remains to be seen, however, what is the duration of the lamps, and whether these thin tubes of carbon are not more rapidly injured by the passage of the current. This, however, requires the test of practical use.

From the economical point of view Mr. Bernstein's arrangement is without doubt as rational as that we have just discussed. The layer of air which fills the hollow carbon

Digitized by Google

likewise constitutes an insulator. But it is not preserved indefinitely, and it is inconvenient in that it helps to deteriorate the tubular envelope, which it eventually traverses. The hotter the air becomes the more it acquires penetrating power, and easily forces a passage through the enlarged pores and agitated molecules of the carbon. Now, as there is no allowance for the variations of the electric current, nor for those which the changes taking place in the ambient medium determine in the radiation, it follows that hollow filaments are subject to intermittent effects of expansion and contraction corresponding to the different caloric charges accumulated in the wire. Hence a disorganising action which is in accordance with the elevation of the temperature, that is, the reduction of section of the filaments. Under these conditions the economy diminishes as the carbons alter. The addition of a refractory support to the tubular carbon permits of the use of an extremely thin film of carbon. It appears, therefore, to be indispensable.

NOTE ON HALL'S PHENOMENON.*

BY HERBERT TOMLINSON.

In a paper entitled "The Influence of Stress and Strain on the Action of Physical Forces,"† I drew attention to the fact that there is a marked resemblance between the table of "rotational coefficients" drawn up by Professor Hall and that laid down by myself from the results of experiments on the effects of mechanical stress on the specific electrical resistance of metals. A comparison of the two tables given below shows that, with the exception of platinum, the metals stand in nearly the same order in both, and that iron and nickel are very conspicuous, the one at the top and the other at the bottom of the lists. The last-named metal is especially worthy of notice, because in it longitudinal traction, when not carried beyond a certain limit, diminishes the electrical resistance in spite of the increase of length and diminution of section which ensues:—

Name of Metal.	Rotational Coefficient.‡	(a)
Iron	+ 78·0	+ 2·618
Zinc	+ 15·0	+ 2·113
Tin	− 0·2	+ 1·630
Lead	0	+ 1·613
Platinum	− 2·4	+ 2·239
Silver	− 8·6	+ 1·617
Copper	− 10·0	+ 1·005
Aluminium	− 50·0	− 0·420
Nickel	− 120·0	− 8·860

(a) Temporary alteration of specific resistance per unit produced by temporary increase of length per unit. + signifies increase of resistance on application of stress.

It might then be suspected that the results obtained by Hall are capable of receiving an explanation in the fact that the electrical resistance of the strips of metal used by him would be altered by the mechanical strain consequent on their endeavour to move across the lines of magnetic force. Mr. Shelford Bidwell has, however, in his recent interesting communications to the Royal Society and the Physical Society, pointed out that "Hall's phenomenon" cannot be thus accounted for. Nevertheless, as it seems not improbable that there is some indirect connection between the alteration of electrical resistance produced by mechanical stress and the "Hall effect," I have little doubt but that experiments on the "rotational coefficient" of nickel, in which the temperature is varied up to 100° C., or in which the strips are subjected to mechanical traction of varied amount, would assist in deciding the question as to whether purely mechanical stresses are to be regarded as producing the phenomenon. For it has been shown* that with this metal the maximum diminution of resistance following from longitudinal traction is at 100° C. *less than one-half* of that at 15°; and, further,† that whilst traction not exceeding a certain limit produces diminution of resistance, increase of stress beyond this limit is followed by increase of resistance. Hall has remarked, in the *Philosophical Magazine* for September, 1881, that the transverse current obtained with a nickel strip is much *increased*, other conditions remaining unchanged, by rise of temperature. But his experiments in this direction are, I think, hardly conclusive; and, indeed, an examination of the numbers given in the column in which the values of the "rotational coefficient" are recorded shows, in the first *ten out of the eighteen* experiments, evidence that rise of temperature causes a *decrease* of the transverse current. Should Hall's phenomenon prove to result from mechanical strain, I incline to the belief that a rise of temperature from 15° to 100° C. will produce decrease in the transverse current.

The experiments of Mr. Bidwell tend very largely to prove that the "Hall effect" can be explained by the joint action of mechanical strain and certain "Peltier effects." Should this be so, we ought, I think, to be able, by means of two thermo-elements connected with each other and with a delicate galvanometer, one element being in a cooled region and the other in a heated region, to put this theory to the test. Or, again, we might cover the strip with some material of bad thermal conductivity, and watch for a gradual increase of transverse current with time when the electro-magnet is excited, and gradual decrease when the electro-magnetic stress is removed. Indeed, in the actual arrangement adopted by Hall and Bidwell it would seem that this gradual increase or decrease should occur; for though the strips themselves would rapidly cool if unmounted and exposed to the air, the nonconducting material of the mounting would take some little time both to gain and lose the heat imparted to it by the strip.

* Communicated by the Physical Society.

† Phil. Trans., Part I., 1883, p. 168.

‡ A + sign attached to a metal signifies that the effect is in a direction the same as that which the conductor itself bearing the current would follow if free to move across the lines of magnetic force under the action of the ordinary "ponderomotive" force.

THE DIAMETER OF CONDUCTORS TO PREVENT OVERHEATING IN ELECTRIC CURRENTS.‡

BY PROFESSOR GEORGE FORBES.

(CONTINUED FROM PAGE 41.)

We now come to the case of insulated conductors. There are two cases which can be taken together—aerial and subaqueous. The mathematical treatment of these is, however, not quite the same. In the subaqueous cable we may assume that the outside of the insulator remains at the temperature of the water. In an aerial line it sometimes happens that the insulator is so thin that its outside becomes quite hot. The mathematical view of this case is nearly the same as that of a copper conductor covered with lampblack, which case has already been treated.

PROBLEM II.

A conductor of radius r_1 is surrounded with an insulator to an outer radius r_2. If the ratio $\frac{r_2}{r_1}$ remains constant, it is required to find the way in which the current C must vary with radius r_1, so that the temperature of the wire shall be t_1 degrees cent. above that of the outside of the insulator.

Let R, as before, be the specific electrical resistance of the conductor in ohms, and let K be the thermal conductivity of the insulator.

Let H be the heat which is generated per second by the current in a length of one centimetre of the conductor.

Then H is also the heat which flows per second radially out of the insulator per centimetre of length. Imagine the insulator to be made up of a number of concentric cylinders, and let the radius of one of them be r and the thickness δr, then the surface of one centimetre length of this cylindrical shell is

‡ Paper read before Society of Telegraph Engineers and Electricians.

Digitized by Google

$2\pi r$; and if $-\delta t$ be the difference of temperature, we have, from Fourier's definition of conductivity,

$$H = -K . \frac{2 \pi r \cdot \delta t}{\delta r}.$$

If we integrate this between the limits $r = r_1$ and $r = r_2$, the difference of temperatures at these points being t_1, we find that

$$\log._e \frac{r_2}{r_1} = \frac{2 \pi K}{H} t_1.$$

Now we also know, from Joule's law, that the heat generated in one centimetre length of the conductor is

$$H = \frac{4 C^2 R}{\pi D_1^2} \times \text{(number of heat units in one watt} = 0{\cdot}24).$$

$$\therefore \log._e \frac{r_2}{r_1} = \frac{\pi^2 K D_1^2}{{\cdot}48 C^2 R} t_1$$

$$C = \sqrt{\frac{\pi^2 D_1^2 \cdot K t_1}{{\cdot}48 R \log._e \frac{D_2}{D_1}}} \quad . \quad . \quad . \quad . \quad (1).$$

It appears from this that when the ratio $\frac{D_2}{D_1}$ is constant the current must vary as the radius of the conductor to produce a constant difference of temperature between the inside and outside of the insulator. But it would be comparatively useless to tabulate the data from this formula, for with aerial cables we must take note of the excess of temperature of the outside of the insulator over the surrounding air. Call this excess t_2. Then, from the method pursued in the investigation for bare wire, E being, as before, the coefficient of radiation and convection, the flow of heat is

$$= \pi D_2 t_2 E ;$$

but it is also

$$= \frac{2 \pi K t_1}{\log._e \frac{D_2}{D_1}}$$

whence

$$\frac{t_1}{t_2} = \frac{D_2 E \cdot \log.^e \frac{D_2}{D_1}}{2 K}$$

putting $E = {\cdot}0003$ (see above) and $K = {\cdot}0005$

$$\frac{t_1}{t_2} = \frac{3}{10} D_2 \log._e \frac{D_2}{D_1} \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$\therefore t = t_1 + t_2 = t_1 \cdot \frac{10 + 3 D_2 \log._e \frac{D_2}{D_1}}{3 D_2 \log._e \frac{D_2}{D_1}} \quad . \quad . \quad . \quad (3)$$

and from (1)

$$C = \sqrt{\left\{ \frac{\pi^2 K D_1^2}{{\cdot}48 R} t \times \frac{3 D_2}{10 + 3 D_2 \log._e \frac{D_2}{D_1}} \right\}}.$$

This formula is one of great interest. From it we can calculate directly the value of the current or the rise in temperature when the other quantities are fixed; and all the problems in connection with such cables as are discussed in this memoir can be dealt with by the help of the same formula. There is another matter of great practical importance which it enables us to solve. We can compare it with the formula (A) for bare copper wire. Call I and I′ the currents in bare and insulated wires which with the same value of D give also the same value of t.

Assume $E = {\cdot}0003$ for insulation, and $E' = {\cdot}0002$ for copper.

$$\frac{I^2}{I'^2} = \frac{D^3 t \cdot \frac{\pi^2 E'}{R \times 4 \times {\cdot}24}}{\frac{D_1^2 D_2 \pi^2 K E \cdot t}{2 \times {\cdot}24 \times R} \cdot \frac{1}{2 K + E \cdot D_2 \log._e \frac{D_2}{D_1}}}$$

$$= \tfrac{2}{3} \times \frac{D^3}{D_1^2 D_2} \cdot \frac{1}{2 K} \cdot \left(2 K + D_2 E \log._e \frac{D_2}{D_1} \right)$$

$$= \tfrac{2}{3} \cdot \frac{D_3}{D_1^2 D_2} \cdot \tfrac{1}{2} \cdot \left(2 + \left[\frac{E}{K} = \tfrac{3}{5} \right] \cdot D_2 \log._e \frac{D_2}{D_1} \right)$$

and $D = D_1$.

Thus we find that I is greater or less than I′, according as

$$2 D_1 \left(2 + \tfrac{3}{5} D_2 \log._e \frac{D_2}{D_1} \right) \text{ is } \gtrless 6 D_2.$$

Take as special cases (1) $D_2 = 2 D_1$ and (2) $D_2 = 4 D_1$.

Then I is $\gtrless$ I′ according as

$$(1)\ 4 + \tfrac{6}{5} D_2 \times {\cdot}693 \text{ is } \gtrless 6 \times 2,$$

$$\text{and } (2)\ 4 + \tfrac{6}{5} D_2 \times 1{\cdot}386 \text{ is } \gtrless 12 \times 2,$$

i.e., according as

$$(1)\ D_2 \text{ is } \gtrless \frac{6 \times 2 \times 5 - 20}{6 \times {\cdot}693} \gtrless 9{\cdot}6,$$

$$\text{and } (2)\ D_2 \text{ is } \gtrless \frac{12 \times 2 \times 5 - 20}{6 \times 1{\cdot}386} \gtrless 12{\cdot}0,$$

or (1) as D_1 is $\gtrless$ 4·8 centimetres,

and (2) as D_1 is $\gtrless$ 3·0 centimetres.

We have now arrived at a most important result, viz., that an insulated wire carries a greater current without overheating than a bare wire, if the diameter be not very great. Assuming the diameter of the cable to be twice that of the conductor, a greater current can be carried in insulated cables than in bare wires up to 4·8 centimetres diameter of conductor. But if the insulated cable have a diameter four times that of the conductor, this is the case up to 3·0 centimetres diameter of conductor.

When the thickness of insulation is made very great, the limiting size of conductor which favours the insulated wire is shown below :—

Diameter of Insulator. / Diameter of Conductor.		Limiting Diameter of Conductor which favours Insulation.
2	....	4·8
4	....	3·0
6	....	2·5
8	....	2·2
10	....	2·0
100	....	1·0

I venture to express the conviction that these results must be looked upon as very surprising. It was hardly to be expected that, by surrounding a copper wire with a bad conductor of heat, we could in any case increase the strength of current which it will carry without overheating. Yet such is clearly the case; and the general explanation of it is that by so doing we increase the surface from which radiation and convection takes place. When, however, we have to deal with large currents in large conductors, and the thickness of insulating material is increased in the same ratio, the heat finds greater difficulty in penetrating so thick a mass, and the insulation becomes objectionable from its bad heat-conducting properties, so as to lead us to the result that the bare iron carries more current than the insulated one without overheating, when the diameter is great.

It has been supposed by some persons that heat will escape far more freely through insulating materials, owing to their sometimes being diathermanous, and allowing heat to be radiated through them. Now, in opposition to this view, I must say that very few such substances are diathermanous, and very seldom are they sufficiently homogeneous to allow the possibility of direct radiation through their mass.

Before I go on with what I have to say, I must now pause to make a few remarks on the problem which has just been solved.

1. *Permanent State.*—The definition of Fourier, which has been made the basis of the calculations, has reference to the case only when heat has been steadily supplied for some time, so that the gradation of temperatures from the hot interior and the cool exterior has reached what is called the permanent state. The time which is required to attain this state varies with the conditions of the case. With an insulated cable this time increases with the thickness of the insulating material. It may often happen that many hours must elapse before this

Digitized by Google

state is arrived at, *i.e.*, before the calculations of the present part of my paper can be applied. It must be noticed that previous to the establishment of the permanent state the heating effect is less injurious; so that in all cases where there is a considerable amount of insulating material the current may, during the first working hours, be considerably in excess of what has been calculated out here as the working current. The reason of this is, that during this preliminary stage the heat is used up in raising the temperature of the insulating material, which serves to cool the conductor.

2. *Specific Heat.*—This leads me to my second remark about the above calculations, viz., the influence of specific heat of the insulator. It has been explained that, after the permanent state has set in, the heat which is generated in the conductor all passes through the insulator to the external air. But previous to that time the heat generated is partly used up in raising each layer of the insulator up to the temperature which it must have when in the permanent state. The quantity of heat used up in this way depends upon the specific heat of the insulator. The specific heat is the number of units of heat required to raise the temperature of one gramme of the material 1° C. This quantity is known for a large number of substances.

A patent has been taken out for resistances of fine wire through which large currents can be made to pass without undue heating, by embedding the wire in cement or plaster of Paris. The cooling effect of the plaster of Paris is dependent upon its specific heat, and is only temporary. After a very long run of a current through such a conductor, the heating may become greater than in air; and, if the temperature be that of red heat, the plaster becomes a good enough conductor to lower the resistance of the combination so as to make it useless.

I have known of cases where much larger currents have been carried through cables than would be possible by the formula: it is probable in these cases that the current was not continued long enough for the permanent distribution of the temperature to be arrived at. Hence the wire carried a larger current without overheating.

3. Let us form some estimate of the work which is required to heat the insulator to its permanent condition. The exact solution of this problem is troublesome, so we must be content with a very general view of the question. If r_1 and r_2 be the radii of the interior and exterior respectively of the insulator, the mass of this material in a centimetre length is $\pi(r_2^2 - r_1^2)$. Its weight is $w\pi(r_2^2 - r_1^2)$, when w is the specific gravity of the insulator. The heat required to raise its temperature 1° C. is $cw\pi(r_2^2 - r_1^2)$, when c is the specific heat of the material. I can find no determination of the specific heat of gutta percha, but, by the analogy of the substances which it most resembles, it is probably about 0·2. We may take this value for the present, remembering that it is desirable to have experiments made upon all the substances used as insulators, so as to know their specific heats. The density of gutta percha is about 1·0. If we take, as an example, the data derived from an experiment in which $c = 500$, $r_1 = \cdot 625$, $r_2 = 5$, we find

$$cw\pi(r_2^2 - r_1^2) = 0{\cdot}2 \times 1{\cdot}0 \times 3{\cdot}1416 \times 24{\cdot}6$$
$$= 15{\cdot}3 \text{ heat units per centimetre length.}$$

And if it is raised on an average 25° C. it requires 25 × 15·3 heat units per centimetre length to establish the state of steady flow.

Now let us see what time it required to generate this heat with the current of 500 amperes.

The specific resistance of copper is ·000001624 ohm at 0° C., ∴ the resistance of one centimetre length of the specified cable is $\frac{\cdot 000001624}{\pi(\cdot 625)^2}$, and the heat generated by 500 amperes is equivalent to $\frac{\cdot 000001624}{\pi(\cdot 625)^2} \times 250{,}000$ watts per centimetre, or $\frac{\cdot 24 \times \cdot 1624 \times 2\cdot 5}{\pi(\cdot 625)^2}$ heat units per second per centimetre $= \cdot 07943$ heat units per second per centimetre. But the heat required to warm up the insulator to its permanent state is 15·3 heat units per centimetre length per degree cent. Hence, supposing that all the heat generated goes to warm up that insulator, and that none passes through it until the permanent state has been attained, it will take $\frac{15\cdot 3 \times 25}{\cdot 079}$ seconds = 1 hour 21 minutes. It is clear, then, that, since during all this time much heat is passing through, it will be many hours before a current of 500 amperes will be able to heat it as much as is implied by the permanent state.

4. It will be readily believed, from what has been said, how necessary it is to know the thermal conductivity of the insulating material employed in cables. Now, it is very important to notice that the thermal conductivity of substances behaves in the same way as the electrical. The late Principal J. D. Forbes showed that the metals lie in the same order for either conductivity, and that iron becomes a worse conductor for heat at higher temperatures, just as it does for electricity. Now, in the winter of 1872-3, I measured the conductivities of a large number of substances* by an extremely accurate method, consisting of freezing water through them. All the values are less than those which have been obtained by other experimenters at higher temperatures, and the low thermal conductivities of non-metallic substances at low temperatures is completely in accordance with their electric conductivities. It appears, then, that for the high temperatures in conductors the thermal conductivity will be higher, and a larger current can be carried than that given by the formulæ and tables of this memoir.

A few comparisons between the results of Herschel and Lebour, Peclet, and myself will show this.

	G. Forbes.	Herschel.	Peclet.
Marble	·00115 to ·00177	·00470 to ·00560	·0048 to ·0097
Slate	·00081 —	·00315 to ·00550	— —
Vulcanised rubber	·000089	—	—
Vulcanite	·000083	—	—
Caoutchouc	—	—	·00041
Gutta percha ...	—	—	·00048

The average temperature of my results is − 10° C.; that of the others about + 40° C.

5. Another point to be considered is, that when exposed to the air the temperature of the outer surface of the insulator is higher than that of the air. If the cable be in water this is not the case, unless excessive currents be used. The case of a cable in water is the most easy to calculate, and is also the most advantageous in practice, as a larger current can be thus conveyed. When it is further considered that under these conditions gutta percha is practically indestructible, we see that in very many cases it will be advantageous to utilise water-power to generate electricity, and the river bed to carry the conductor to the place where the electricity is to be used.

It has often been noticed that the insulation of leads is unaffected by a few hours' run, but are quite hot and soft after twenty-four or thirty hours. This is completely accounted for by what has now been said.

A general result of this investigation is that an electric insulator should have as high a thermal conductivity and as high a specific heat as possible.

Having now discussed fully the conditions of the problem of a cable in air or water, I have computed a table for wires from 1mm. to 10cm diameter, in which the diameter of the insulated cable is four times that of the conductor (this being, as I find from makers' price lists, a common ratio), showing the current which will raise the temperatures $t°$ C. above those of the surrounding air. [Table A is substituted for one exhibited to the society, as it is of more practical value.]

Subaqueous and Aërial Cables (insulated)—

$$\frac{\text{Diameter of cable}}{\text{Diameter of conductor}} = 4.$$

Temperature of air = 20° C.

t = excess of temperature of conductor over air.

* Proceedings Royal Society, Edinburgh, 1873.

Digitized by Google

Computed from the formula,

$$C = \sqrt{\left\{ \frac{\pi^2 D_1^2 K}{\cdot 48 R} . t \times \frac{3 D_2}{10 + 3 D_2 \log._\epsilon \frac{D_2}{D_1}} \right\}}$$

K = thermal conductivity of insulator, = ·00048 for gutta percha; e = coefficient of cooling, = ·0003.

Buried Conductors.—The case of conductors buried underground is difficult to treat mathematically. I content myself with a study of a favourable case, viz., when the conductor takes the form of a thin sheet lying in a horizontal plane under the ground. This form requires far less metal than any other. The heat which is created by the current is at first largely absorbed in heating up the earth near to it, but after some hours a tolerably permanent state sets in, when a very small amount of heat is still penetrating downwards; but the greater part is conducted through the superincumbent earth and paving, and thence cooled by radiation and convection.

With regard to conduction into the soil, we have some experience from the observations which have been made on the temperature at various depths in the soil or in rock. The daily and yearly variations of temperature produce waves of heat in the soil, which are slowly propogated. At a depth of 25 feet the maximum heat occurs in midwinter, and the annual variation of temperature is only $\frac{1}{23}$ of what it is at the surface.

At a depth of two feet the daily variations of temperature are barely perceptible. In the buried cable the heat generated in the dark hours will not all be dissipated at once, but there will be a steady flow of heat at the surface day and night.

(TO BE CONTINUED.)

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The West Indian Panama Telegraph Company is, says the *Pall Mall Gazette*, in rather a curious position. For some time past it has found itself unable to make any profit worth speaking of, and in order to put itself upon a commercial basis it is proposed that the various colonies which it serves should increase the subsidy. All the colonies have agreed except Barbadoes. Until Barbadoes gives way none of the other colonies will grant them an extra penny. If the company were to Boycott Barbadoes all the other colonies would stop their subsidies. The consequence is that matters are in a deadlock. They can neither bring Barbadoes to reason nor carry on without the increased subsidy which Barbadoes vetoes. What the end of it will be no one knows. But it is very hard on the company that a subsidy which they admittedly deserve should be withheld owing to the caprice or obstinacy of a single small island.

TELPHERAGE.*

BY PROF. FLEEMING JENKIN, LL.D., F.R.S.

(CONCLUDED FROM PAGE 43.)

The truck is completed by a small hook or catch embracing the rod. In case of any accident causing the wheels to leave the line this hook will prevent the truck from falling. The weight of the two-wheel stiff truck, shown in Fig. 5, with wrought-iron buckets, is 75lb. The weight of the two-wheel pivoted trucks, with wooden bucket, is 63lb. They are both adapted to carry 2cwt. Fig. 7 shows a one-wheeled truck tested—the results were not favourable. A special form of bucket must be designed to suit such kind of traffic. Simple iron hooks for sacks will, in many cases, be available, and these hooks can be so contrived that on being struck they will drop the sack.

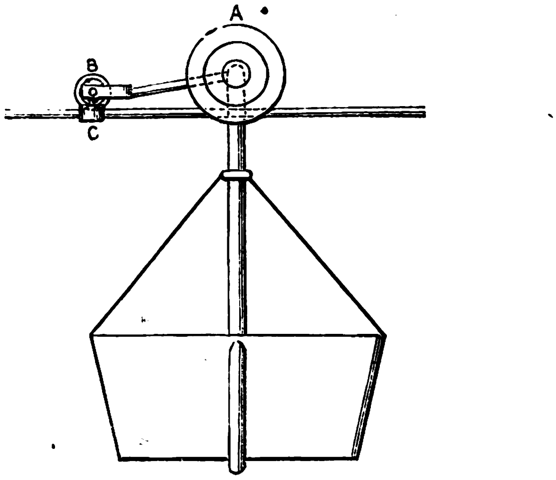

FIG. 7.

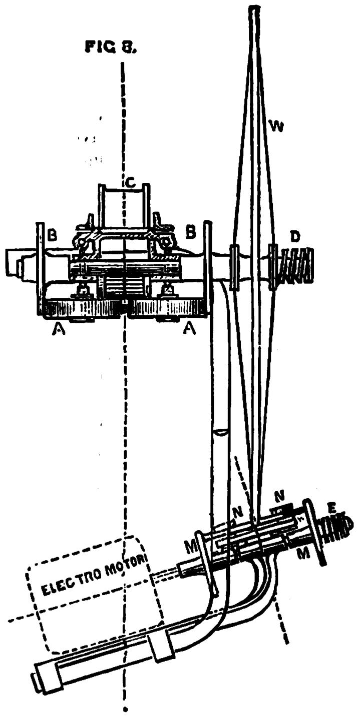
The first type of locomotive which was tried on a large scale is shown in Figs. 8 and 9. The motor lies horizontally across the line, and is connected by a form of frictional gearing, which I term right angle nest gearing, with the edge of a bicycle wheel, W. The shaft of the bicycle has on it two discs, B B, one of which is fixed on the shaft, while the other can slide longitudinally on the shaft.

FIG 8.



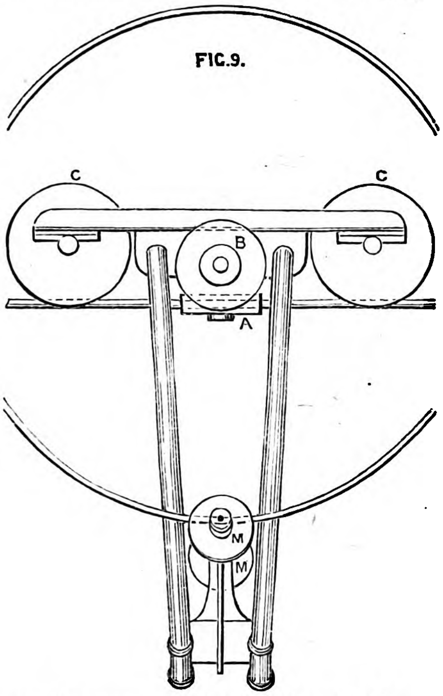
These two discs are pressed together by a spring, D. Their edges bear on the horizontal gripping rollers, A and A, which seize the line. These rollers are supported in such a way as to be free to come together under the pressure of the spring transmitted by the discs B and B. By tightening the spring any required grip can be obtained with no injurious friction either on the cross shaft or on the spindles of the rollers. This grip is a form of right angle nest gearing. The weight of the locomotive was taken by wheels, C C, fore and aft. The following defects were observed:—The

* Paper read before the Society of Arts, Wednesday, May 14, 1884.

Digitized by Google

frictional surfaces, both in the upper and lower nests, were too small, and the materials too soft, so that rapid wearing resulted, with a consequent increase of friction. Moreover, the grip was so powerful that the rollers A A were capable of supporting the weight, and thus a small inclination of their vertical axis was enough to cause the locomotive to rise, and even run off the line; moreover, the vertical curvature in the rope or at the posts required the rollers A A to be deep, thus limiting the extent to which rocking was admissible; moreover, very broad pulleys, fore and aft, would be required even for moderate horizontal curves. Nevertheless, this locomotive ran sufficiently well on the 1in. line during an exhibition to the shareholders last autumn. The weight for a five-eight line of a somewhat improved form of this type, to exert one

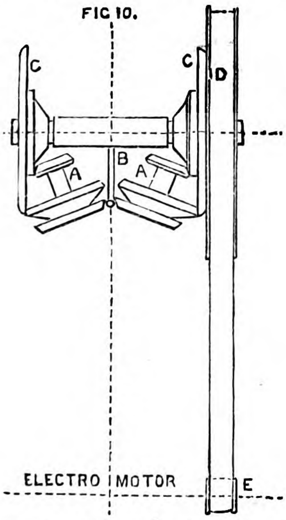
FIG.9.



horse-power, on the average is 200lb. with a half-horse motor. The driving wheels A A of this example are 6½in. diameter. The motor makes 9·23 revolutions for one of the driving wheels. One mile per hour corresponds to 473 revolutions per minute of the motor. 37in. pounds at the motor spindle are required for a pull of 100lb. at the rail.

Figs. 10 and 11 show a locomotive designed by Mr. A. C. Jameson, when I was personally unable to attend to work. This locomotive, which is called the belt locomotive, shows a great advance on its predecessor. The general arrangement of the upper nest grip

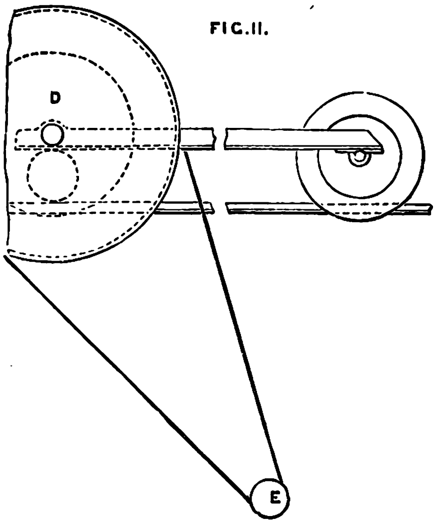
FIG 10.



is retained, but a most ingenious modification has been introduced by which the discs C C run on one path on the rollers A A, while the rod runs on another. In this way the dirt from the line is never conveyed to the driving disc surface between A and C. Moreover these frictional surfaces, which are points in the first form, have become lines in the second. This head answers admirably. The weight is carried by a roller, B, between the gripping discs, an arrangement contained in one of my first small models, and wrongly rejected in the first large locomotive. With this subdivision of weight the gripping wheels are much less likely to rise, and can be made very shallow. In the actual locomotive these gripping wheels are of an open inverted Λ shape, which has certainly run very well, although I prefer at present the upright V shape, which closes under the rail, as used in the model before you. Both of the gripping rollers drive, as in the first type. The cross shaft is driven by a belt on a 20in. pulley, D, the pulley E on the motor spindle. The friction due to the pull of this belt on the motor spindle is relieved by friction rollers. This locomotive runs extemely safely and steadily on the line; indeed, I am not aware that it has ever been thrown off.

The following are particulars of its construction:—Weights with 96lb.; motor, 269lb.; wheel-base, 2ft. 6in.; diameters of driving rollers, 6in.; 4·94 revolutions of motor per one revolution of driving wheel. A couple of 60·6in. lb. on motor is required for 100lb pull at rail; 276 revolutions of motor correspond to one mile per hour on the rail.

FIG.11.



The only improvements I have to suggest in this design are:—1st, the addition of gear, which will give a higher speed of motor for the normal speed of four miles per hour, which we contemplate; 2nd, the addition of a swivel or bogie arm, such as is used in the model before you; 3rd, improvements in the belt connection. Moreover, the machine requires strengthening in some places. It will, however, be seen that none of these points touch the essential features of the design, which might at once be adopted in practice. Worked with motors of the Gramme type, the additional gear would not be required.

Before the belt locomotive had been completed it was necessary to design a locomotive for the South American line, which I have

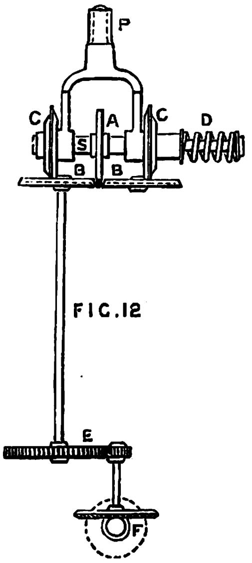


FIG.12

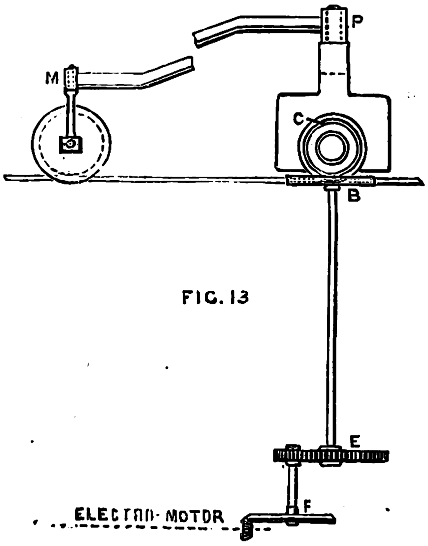

FIG. 13

several times mentioned. I had meanwhile constructed the model which is now before you; and this little locomotive, in which the power is transmitted by ordinary spur wheels, ran so extremely well that I adopted the general arrangement for the next example on a large scale. This arrangement is shown in Figs. 12 and 13, the grip (C C and B B) is a third variety of the right angle nest, simpler than that in the belt locomotive. In this form, also, we have line contacts, and two paths for the discs and rod. Where it is desired to drive from both sides this arrangement is less powerful than that in the belt locomotive. In the South American locomotive

Digitized by Google

I drive from one side only, leaving the off side roller free to revolve as it pleases; this avoids grinding at rapid curves, and the adhesion given by one wheel will be ample in a dry country, such as that where this locomotive is to work. The arrangement of the gearing E and F is obvious; it allows the locomotive to lie fore and aft instead of across the line, and this arrangement has some advantages in the adjustment of the weights. The surfaces of the gripping wheels are arranged like an upright V, so as to hold on under the line. This makes it very difficult for the wheels to leave the line, both because of their absolute hold and because the inclination of the V is such as to favour the action of gravitation in overcoming the friction of the grip, instead of opposing it as in the inverted V.

Another feature of this machine is the arm pivoted at P, and carrying the leading wheel, which is again pivoted at M in the arm, as in the case of the trucks. This arrangement allows the locomotive to traverse curves of 6ft. radius—a very remarkable result.

The full-sized locomotive has only just been completed, and run on three spans at Messrs. Easton and Anderson's. So far as I am able to judge from the trial, it is likely to be a complete success. It will be immediately shipped for its destination, so that its performance cannot be more fully tested in this country. The following particulars will show that it is much more powerful than the belt locomotive, but it is considerably heavier:—Wheel-base, 2ft. 6in.; weight, about 3 cwt. 14lb.; 15 revolutions of motor per revolution of driving wheels; diameter of driving wheels, 10in.; 33·3in. lb. per 100lb. pull at rail; 504 revolutions of motor per minute for one mile per hour.

I am in doubt at this moment whether to adopt the belt locomotive or the spur wheel locomotive for the next example. It is simply a question of cost, weight, and durability. Either will do the work.

In all the arrangements it is essential that the second bearing wheel should lead, not follow the drivers in regular work. The reverse arrangement lets the rope lead on at an angle with the plane of the roller, causing an injurious grinding action.

Details of couplings have been well worked out, but space fails for their description.

As general features of the train running on the line, I may mention that the deflection of the rod within reasonable limits has very small influence on the resistance. When the deflection on a 50ft. span was about 2·4ft., the resistance for a train of trucks, weighing in all 1,260lb., was 22lb.; and no sensible difference could be detected when the deflection was materially reduced. This resistance was measured by pulling a train along, span after span, by one end of a rope passing over a pulley on the leading truck, and having a weight hanging vertically from the other end of the rope; the weight thus limited the pull. This pull differs extremely little as the train moves along, for when one part of the train is descending the curve the other part is ascending. It should be noted that during this experiment no special care had been taken to oil the bearings, and I have no doubt this pull can be materially reduced.

I have ventured to dwell at some length on the mechanical problems involved in this form of telpherage, because the experiments made so far have chiefly borne on questions of mechanics. The makers of dynamos can put at our disposal apparatus which will generate day after day, with perfect certainty and regularity, currents of electricity such as will transmit the horse-power generated by powerful steam-engines. These makers have already solved the chief electrical problems which present themselves in connection with telpher lines. They can give us at will constant current or constant electromotive force, high or low, as we may choose. They are now able to arrange their apparatus so that any number of incandescent lamps may be turned off or on without disturbing the regularity with which other lamps are supplied, and by the same arrangement we are enabled to start or stop any number of telpher trains without disturbing the running of others. The electrical problems of the telpher line, and those of electric lighting, run in absolutely parallel lines.

The electric motor, although it may be termed a mere inversion of the dynamo, has not as yet been brought to equal perfection, but month by month improved designs, proportions, and materials are being introduced, and the result already obtained is sufficient for our purpose. It is all the more encouraging to feel that these results will certainly be surpassed, and far surpassed, in the immediate future.

The following short summary of the problem of the transmission of power by means of electricity may interest those who have not studied the subject. There are three steps in this transmission—1st, we convert mechanical power into electricity by means of a dynamo; in doing so we incur a loss of from 10 to 20 per cent. 2nd. This electricity, in flowing along a conductor, generates heat, representing a further loss analogous to that resulting from friction in mechanical gearing. This loss, depending on the distance of transmission, the size of the conductor, and the electromotive force employed, is easily computed. 3rd. We re-convert the electricity into mechanical power by means of an inverted dynamo, which we term an electric motor. With motors in which large weights of iron and copper are employed, the loss in re-conversion need not exceed 20 per cent., but with light motors, weighing from 70lb. to 100lb. per horse-power, such as we must employ in the locomotives, I could not undertake with certainty at this moment to effect the re-conversion without a waste of one-half. The effect of all these sources of loss is, that at the stationary engine I must exert about 3 horse-power for every single horse-power which is employed usefully on the line. I look forward confidently to the time when 2 horse-power at the engine will be sufficient to give 1 horse-power to the motor.

To put these conclusions in a more scientific form, I may assume the efficiency of my dynamo as 80 per cent., that of my light motor as 50 per cent. The waste by heat expressed as horse-power is equal to $\frac{C^2R}{746}$, where C is the current in amperes, and R the resistance in ohms. The horse-power represented by the current is equal to $\frac{E \cdot C}{746}$, where E is the electromotive force in volts, and C the current in amperes. It follows from the last expression that I may increase the horse-power in three ways, by increasing either E or C, or both. If I increase E, leaving C the same, I do not increase the loss during transmission along the line, no matter what horse-power the given line may transmit. A practical limit is set to the application of this law by the difficulty met with in dealing with electromotive forces above 2,000 volts. Marcel Deprez, taking advantage of this law—first pointed out by Sir William Thomson—has transmitted 7 or 8 horse-power over seven or eight miles, through an ordinary telegraph wire, and he obtained a useful duty of 63 per cent., taking into account all the three sources of loss which I have enumerated. With small motors I cannot yet promise a result so good as this, and I merely mention it to let you understand that, in speaking of 3 horse-power for one at the locomotive, I am leaving a very ample margin.

Quitting generalities, I will give some details as to the electrical and other conditions necessary, in two examples, for what may be considered as typical telpher lines:—

First Line.—Length, five miles. Length of circuit, out and in, ten miles. Twenty-five trains running at once, space one-fifth of a mile apart; speed, four miles per hour. Let each require 1 horse-power on the average; let the motor take on the average two amperes of electric current; let the electromotive force near the stationary engine be 840 volts; the electromotive force at the end of five miles will be about 746 volts. The total current entering the line will be fifty amperes at the near end of the line. Fifty amperes and 840 volts represent 56·5 horse-power; of this 6·5 horse-power will be wasted in heating the line; the remaining 50 horse-power will do work in the motors equivalent to 25 horse-power. In order to give this current of fifty amperes with 840 volts, the stationary engine will require to exert $\frac{10}{8} \times 56$ horse-power, or, roughly, 70 indicated horse-power, or somewhat less than three times the useful horse-power. Let us now examine the economical results to be obtained from such a line as this. Mr. Dowson, in an interesting comparison between the cost of horse-power obtained from coal and gas, reckoned the cost per horse-power for a 100 horse-power engine at the rate of £3 6s. 9d. per annum, to include wages, coal, oil, and depreciation. Mr. Dowson would naturally be led to put the cost of steam power obtained from coal rather high than low. I will, however, adopt a very much higher figure, and assume that the power may cost as much as £6 10s. per horse per annum; this gives £455 as the cost of the 70 horse-power required for my telpher line.

Let the 25 trains each convey a useful load of 15cwt. In a day of eight hours the line will have conveyed a traffic which we may express as 600 ton-miles—*i.e.*, it will be equivalent to 600 tons conveyed one mile, or 60 tons on each line conveyed from end to end daily. If we count 300 working days in the year, the sum of £455 gives £1 10s. 4d. per diem, and the 600th part of this is about 0·604 of a penny as the cost of the power required to carry a ton one mile.

In Great Britain we ought easily to be able to reduce this below a halfpenny per ton per mile, which proves that the apparent great waste, even of two-thirds of the power in transmission, does not involve prohibitory expense. In calculating the whole cost of transport, we must further take into consideration the cost of the installation. Taking the spans at 70ft., I estimate this cost as follows:—

Line £500 per mile	£2,500
Engine, boiler, and shed, at £20 per indicated horse-power	1,400
Dynamo and fittings	1,000
Twenty-five trains	2,500
Contingencies	600
Total cost	£8,000

Digitized by Google

Allowing 12½ per cent. for interest and depreciation, this represents an annual cost of £1,000. Allowing £100 as the salary of an electrician or young engineer, and adding £455, the cost of the power, this gives a total annual expenditure of £1,555 for a daily duty of 600 ton-miles. If we continue to assume the year as containing 300 working days, the total cost of conveying one ton one mile will be found equal to 2·07d. If goods are to be transmitted for long distances, the same calculation applies. We should simply have stations ten miles apart, working lines five miles long on each side of them. This, then, is the practical outcome of the general principles stated at the beginning of this paper. We may expect with great confidence to being able to convey goods for any distance at the rate of 2d. per ton per mile by the agency of the suspended telpher line.

Matters are somewhat modified when the traffic is smaller. Making similar calculations for a line one mile long instead of five, with only four trains running at once, we might employ an electromotive force as low as 100 volts; the loss by heating would be insignificant; we should require about 12 horse-power; the work done in eight hours would be 96 ton-miles. I estimate the cost of installation at £1,600, and the annual cost of working £344, without the annual salary of an electrician. This corresponds to 2·875d., or less than 3d. per ton per mile. One very important feature in respect to the cost of telpher lines is the fact that the larger part of that cost is due to plant, such as locomotives, trains, and dynamos. This plant can be increased in proportion to the work required; thus there is a very moderate increase of cost in the rate per ton per mile for a small traffic as compared with a large one, and, on the other hand, a line laid down for a small traffic will accommodate a much larger traffic with no fresh outlay on the line itself.

There are numerous minor electrical problems involved, but time does not permit me to enter into the consideration of these to-night. It will be sufficient for electricians when I say that I see my way to governing, blocking, and breaking the trains, without ever interrupting the current used to work the motor, except between the line and rolling wheels. At this point we already know that the interruption, although accompanied by a spark, does no injury whatever. I have often been asked whether the frequent reversals involved in the cross-over system do not tend either to injure the dynamo or the motor. I made special experiments on this very point lately with a compound wound Crompton dynamo and Mr. Reckenzaun's motor with thirty-six coils. I was unable at the commutator of the motor to detect the smallest change in the motion due to the most rapid reversal. At the dynamo commutator I could just see when the reversal occurred, but there was no change of a character to cause the smallest alarm. At the same time I may state that, when from any cause reversals may be thought undesirable, we are in possession of apparatus which we call "step overs," which, without diminishing the simplicity of the permanent way, enable us to send a continuous and unreversed current. These and similar electrical questions, such as the performance of Messrs. Ayrton and Perry's excellent motors, might possibly have had greater interest for electricians than some of the mechanical details discussed to-night; but I have felt that the main point to establish, in bringing this invention before the public, is that we have in telpher lines a means of conveying goods in an economical manner, by lines, locomotives, trucks, dynamos, and motors, which have undergone their preliminary trials with success, and can be at once applied to the more searching test of performing work for the public. If I have established this fact, I think you will have no difficulty in believing that the subsidiary electrical problems have been, or will be, readily solved. I hope that at a future period these will be brought before you in detail on many occasions and by many men.

In conclusion, I will enumerate some of the uses to which telpher lines may be put. They will convey goods, such as grain, coals, and all kinds of minerals, gravel, sand, meat, fish, salt, manure, fruit, vegetables; in fact, all goods which can be divided conveniently into parcels of two or three hundredweight. If it were necessary, I should feel no hesitation in designing lines to carry 5 or 6 cwt. in each truck. The lines will carry even larger weights when these, like planks or poles, can be carried by suspension from several coupled trucks. The lines admit of steep inclines; they also admit of very sharp curves. Mere way leaves are required for their establishment, since they do not interfere with the agricultural use of the ground. They could be established instead of piers, leading out to sea, where they would load and unload ships. With special designs, they could even take goods from the hold of a ship and deliver them into any floor of a warehouse miles away. When established in countries where no road exists, the line could bring up its own materials, as a railway does. Moreover, wherever these lines are established, they will be so many sources of power, which can be tapped at any point, for the execution of work by the wayside. Circular saws, or agricultural implements, could be driven by wires connected with the line, and this without stopping the traffic on the line itself. In fine, while I do not believe that the suspended telpher lines will ever compete successfully with railways, where the traffic is sufficient to pay a dividend on a large capital, I do believe that telpher lines will find a very extended use as feeders to railways in old countries, and as the cheapest mode of transport in new countries. In presenting this view to you, I rest my argument mainly on the cost of different modes of transport, which may, I believe, be stated approximately as follows:—Railway, 1d. per ton per mile; cartage, 1s. per ton per mile; telpher lines, 2d. per ton per mile. And let it be remembered that, in taking the cost of cartage at 1s. per mile, the first cost and maintenance of the road is left wholly out of account; whereas, in my calculations for the telpher line, allowance has been made both for establishment and maintenance.

THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

At the meeting of this society, the last of the summer session, held at Great George-street on May 22nd, Professor Adams presiding, Mr. W. H. PREECE, F.R.S., past president, gave an account of the proceedings and decisions arrived at by the Paris Electrical Congresses. The chairman first announced with reference to the proposed conference at the Health Exhibition that it had been arranged to commence it at 11 o'clock a.m. on July 3rd, when Mr. Crompton would read an address on "Electricity in Relation to Health," and Mr. Stone one on the "Relation of Electricity to Medical Science." Tickets for admission to the conference would be issued to members of this society. Mr. PREECE then followed, referring first to the Congress of 1881 as a memorable epoch in electrical science, and one reflecting the highest credit on the French Government for their extreme liberality in voting 300,000f. towards the expenses, and on the French nation in general for their capital powers of organisation and the warmth of their hospitality. At this first Congress there were 78 representative French electricians, 38 English electricians, and a like proportion representing other nations. Under M. Cochery's direction chiefly, the work was divided into three sections, a division maintained throughout the subsequent Congresses. First there was one devoted chiefly to telegraphy and telephony, the other two being taken up with electric light, lightning, electrical physiology, electro-metallurgy, and the like subjects.

This gathering in the autumn of 1881 was, however, largely devoted to talk, to clearing the air, so to speak, and to ascertaining the real objects of the Congress. But one thing was practically decided upon, namely, the adoption of the C.G.S. system of measurement, the highest possible compliment that could be paid to the magnificent labours of our own British Association. Several meetings were also held at which the subjects of electric lighting and the electrical transmission of power were fully discussed by the leading electricians of all nations. At the second Congress, held in October, 1882, the attendance was not so numerous, there being about 45 representatives present, of whom only one came from this country. The subjects discussed were earth currents, atmospheric electricity, a proper standard of light, and a fixed one for the ohm. It was finally decided that their further consideration should be postponed in order that observations might be carefully made before the next meeting, which would have the benefit of a greater number of facts to go upon than was then before it. In April of the present year the Congress met again, with a muster of 50 members, including amongst them Sir W. Thomson, Prof. Carey Forster, Prof. Adams, Mr. Graves, Mr. Preece, Prof. Fleeming Jenkin, Prof. Hughes, and Capt. Abney. The result was an agreement with respect to the standard or "legal" ohm, a result which cannot fail to be highly beneficial to electrical research in the future. The legal ohm will now be the resistance of a column of mercury, one square millimetre in section, and 106 centimetres in length, at the temperature of melting ice. We published the particulars of this and the other recommendations of the Congress in our issue of May 10th. With regard to the standard of light fixed upon by the Congress Mr. Preece did not speak very highly. It was adopted, he thought, because no one had a better to suggest.

After reviewing the history of electrical measurement, especially referring to the labours of our countryman, Joule, whose standard differed only slightly from that which has now received an international recognition, Mr. Preece concluded by offering a warm tribute to the French authorities for their kindly reception of the representatives, for their excellent management, and for the zeal with which they promoted and brought to a successful conclusion a work which will prove of lasting benefit to the electrical world. A hearty vote of thanks accorded to Mr. Preece concluded the proceedings.

COMPANIES' MEETINGS.

Consolidated Telephone Construction and Maintenance Company (Limited).

The third ordinary general meeting of this Company was held on the 23rd inst., at the Cannon-street Hotel, under the presidency of Colonel Gouraud.

The Secretary (Mr. Charles Curtoys) read the notice convening the meeting, and the report of the directors was taken as read.

The Chairman having referred with regret to the absence of Sir Julius Vogel (the chairman of the Company, who is abroad), observed that the first matter which would have struck the eye of the shareholders in the report of the directors, after the necessary reference to the accounts of the Company, was in Paragraph 4, which stated that the results of the working were anything but satisfactory. They had gone on to point to some of the causes which had led to that state of things. They were very few—indeed two circumstances constituted the principal if not the sole causes of these results. All the original shareholders would remember the circumstances under which the Company was formed; but there were a great many among them who were not original shareholders, and it had therefore been necessary to point out that very important feature in the position of the Company. The reference in the report to the Postmaster-General's contract perhaps required a little explanation beyond that given in the report. Those who were thoroughly acquainted with the position of the Company with respect to its contracts knew that the Company stood in a peculiar position. At the time of its formation the United Company was supposed to be the owner of the master patent controlling the use of the telephone; but the Postmaster-General, at the time, with a view to protecting what he conceived to be the interest of the Government under the Telegraph Act, acquired the right to use a large number of telephones—telephones which were made under the patents of the United Company, and a modification—one of an infinite variety of modifications that might be made of the instrument. It was thought by some to be independent of the United Company's patent, and no doubt the Postmaster-General thought so; but what the shareholders of the Company had presented to them was that the Postmaster-General had made a contract implying a very large business. On the other hand this Company at the same time acquired the exclusive right to the manufacture, for the United Company and its subsidiary companies, of all the telephones which they at any time might require. The effect of that combination was that it would appear—and he thought rightly—that this Company stood in the position of being absolutely certain that it would have the manufacturing business of the telephone—of all the telephones used in this country, or that were manufactured in this country for export, the latter provision being also contemplated by the arrangement with the United Company. Well, the business was started, and it seemed impossible to meet the demand for telephones in the early days of the operations of the Company. They were pressed on the right and on the left, both by the Postmaster-General and by the United Company, and though the Company took premises which were at first considered to be adequate, they soon had to remove to larger quarters. During the first period of their business the manufacturing business was very large—so large that the profits derived, quite apart from any business with the United Company, were sufficient from the Postmaster-General's contract alone to pay a substantial dividend on the whole capital of the Company. There suddenly, however, came a check to the business of the Company. From being pressed to deliver beyond the capacity of any manufacturing company so young and engaged in so new a pursuit, there were comparatively no orders—scarcely any from the Post Office, and a little later none at all. That was a serious thing for a manufacturing company. The orders, too, from the United Company were surprisingly small. That state of things unfortunately continued now, and they all very naturally wanted to know why this was. He had that morning taken certain figures from the records of the United Company, and he would give them in comparison with others. They must understand in connection with these figures that the telephone was the telephone in whatsoever country it might be used, for it spoke all languages alike. Any differences in the development of the enterprise, therefore, could not be attributed to the telephone being superior in one place and inferior in another. They all used the Edison and Bell invention in one form or another, and business was all begun about the same time—in this country perhaps a very little later. That day they found, representing all the subscribers of the United Company and its subsidiary companies—which were the only people doing the business to any extent in this country except the Post Office—that there were 10,507 exchange subscribers. That was for all the United Kingdom, for a country with a population of forty millions odd. The private wire subscribers numbered 2,000—that was to say, private wires from one's house to one's works. There were thus seventy-two exchanges, with an aggregate number of 10,507 subscribers, and 2,000 private wire subscribers. If they knew no more than that it might be thought that this represented very good business; and so it was for the people who were doing it. The Post Office had also twenty-five exchanges opened in competition with the United Company, but that was a matter of no concern to this Company, because it was of no consequence who did the business, the Post Office or the United Company.

A Shareholder: How many exchanges have the Post Office got?

The Chairman: Twenty-five; and in the speech of the Postmaster-General last evening he stated that his subscribers numbered about 700. That was the position of the telephone business in this country that day, with the single exception of the business being done by the London and Globe Company; and to be perfectly accurate as to the state of the business in this country he would include that company's operations. That company's business was, he said, to work an exchange in London chiefly, and they had an exchange with, he believed, about 100 subscribers. He would now quote from an official document, dated October last, and the facts mentioned therein were even more astonishing, brought down to a later date. In America, the birthplace of this invention, there were in October last ninety-four exchanges in the principal centres of business, and the figures he had previously given were based on the principal centres of the United Kingdom. The comparison was therefore a fair one. Those ninety-four exchanges were located in commercial centres with an aggregate population of 6,500,000, and they found that the number of the subscribers was 35,360, the ratio to the population being one subscriber for every 188 people. On his way to the meeting he had made a rough comparison to show what that would mean if there had been relatively the same development in this country, which they were, he maintained, reasonably entitled to have; and he had found that they ought to have in London alone 20,000 subscribers, whereas they had under 4,000—in round figures, about 3,500. Those facts bore vitally on the position of the Company. When they came to look for a reason for this result they could find only one. He did not believe that the shareholders any more than the directors would admit that the English people were behind the rest of the world in their intelligence or in their appreciation of a good thing, so that the small progress made in the development of the telephone could not be attributed to that. They believed, in fact, that they could put their finger on the real cause. In the report of the directors they stated that it was owing chiefly to the restrictions imposed on the enterprise by the Government. He did not mean to apply any hostile criticism to the Postmaster-General. They knew, however, the result of the operation of the law, as decided by the Courts, when the companies concluded to admit—from motives of policy rather than from any conviction as to the justice of what they did—that the telephone was in the Postmaster-General's monopoly. Since then they had been subject to the control of the Government, and that had been exercised in one vital respect, with the result shown in the figures he had read to them. The control he referred to was the limit of the operations of the companies' exchanges to the narrow radius of five miles from the centres. Nothing else could explain it. The same restriction did not exist in other countries except in some of the English colonies, notably in India. It was not for him to say that the views of the companies were right on this question and that the Postmaster-General was wrong, but what he had stated must be taken as the cause for the restricted development of the telephone in this country; and he wanted no better authority for that statement than the Postmaster-General's remarks made only on the previous night, and reported in *The Times* of that day. He ought to tell them that during the last two years negotiations had been going on with the Post Office to open this business up and for connecting telephones together. There was no reason why every member of a company should not be able to go into an office and speak to his correspondent anywhere in the United Kingdom except the restriction of the Post Office. Proposals had been made by the companies and counter proposals by the Postmaster-General running over two years. There had been more time spent by the Board of the United Company, and more particularly by the able chairman of the Company, on these negotiations with the Post Office than, he ventured to say, had been spent on any other matter, or on all the other business of the United Company during those two years, and it had only been from the knowledge of their rights and of the value of the enterprise that those connected with the telephone business had stood on their ground. They had refused to accept licences that were prohibitive and involved a large outlay of capital without a prospect of some return on it. On the previous night Mr. Fawcett, in the House of Commons, stated in substance that he had at length arrived at the conclusion that his policy on that point was wrong—and perhaps upon an equally important point he was wrong—and that he would take the question into his early reconsideration. That was the assurance which the Postmaster-General gave to Mr. Gray, to whom his remarks were addressed in reply to questions. The other question was the character of the licences the Postmaster-General had insisted on their taking if they required any more. There were only 72 exchanges in the United Kingdom, and many of these were under the same licence; but for a long time the Government had insisted—and this was a very important point for the shareholders to know—that in any further licences the companies accepting them must agree to sell to the Postmaster-General any telephones they might use at a price to be agreed on, or subject to arbitration. The Postmaster-General, however, was to have the right of buying, whereas he had not the right to buy telephones now except from this Company. He had insisted on buying any telephones from companies accepting the licences now granted, and he did not stop there, for he had also insisted that he should have the right to lease or sell these telephones. They could all see what an encouragement that would be to infringements of patents, and if the patents of the United Company and of this Company were to be infringed in that way—telephones used by any one who might please to use them—then they would have no rights other than those belonging to any other competitor. That was the reason they had done no more manufacturing business. The report of the directors contained no predictions as to the future. The Board determined to give the shareholders all the facts. There was, according to the statement on the previous night of the Postmaster-General, to be a reconsideration of the position as to the telephone, and it might be that the result would be so liberal in the interest of the public that it might give a fair start and fair play to the telephone. The United Company was bound in its contract with this Company to defend the telephone, and it had been doing so with unprecedented success. It had never yet lost an action. If there was to be fair play with respect to the telephone they must have a large business, and if so, and they con-

ducted it properly, they ought to make money. For their contracts, which they had not made much out of in the last two years, this Company paid enormous sums of money. Out of the £137,500 paid for goodwill, patent rights, &c., he supposed—though it would be difficult to fix the exact figure—that it would be right to say that £100,000 was paid for the Postmaster-General's contract.

A SHAREHOLDER inquired to whom the money was paid.

The CHAIRMAN replied to the combination which represented the contract. The other business was the export business. It was to be understood that there was not a very large working capital left—only a little over £50,000, and the Company undertook enterprises which it expected to be relieved of sooner. They had succeeded in this to a certain extent. About a year ago, in order to meet the deficiency shown, a further issue of capital was offered to the public, but it was not sufficiently adequate to support the enterprises in question. As to the Austrian business, on the occasion of their last general meeting the chairman made certain statements concerning its position at the time, informing them that the financial embarrassments of the Company were relieved. They were relieved undoubtedly in so far as the capital coming from the new issue sufficed, but it was only a temporary relief, because the business to which the Company was committed in Austria required more and more money. He was not on the Board at the time the Austrian business was undertaken, but he was perfectly conversant with the views of the Board at the time, and their idea was that with a little money put into the concern and the business started it would be easy to form a separate company for it, and get the necessary capital for developing it. The times, however, had not been favourable to get the capital required. So much for the business in Austria. He went there last summer, and spent some weeks there, and by taking very strong ground with the vendors he improved the position of the Company in this very important respect—that he limited what had been an unlimited liability; and therefore at any rate they knew where they were with respect to that question. His colleague, Mr. Carnegy, reminded him that he ought to tell them that when he spoke of the embarrassments of the Company as to its Austrian business, it was only as to want of capital. He believed that that was so. The business was a very good one. It had practically obtained concessions, which it was very difficult to get, for nine of the principal towns of Austria, excluding Vienna. The business had been started in all these places, and there were a certain number of subscribers at all of them. The only thing the business wanted now was money, and the only actual liability this Company had in respect of the Austrian business was a sum of money which was spent for the account of this Company. That was one of the terms of the compromise he made last summer; but that liability had not yet matured. He had, however, been in communication with the vendors in anticipation of its maturing, and he had, he believed, succeeded in convincing them that it would be to their interest to meet the views of the directors of this Company as to some further modification. Perhaps the most important feature in the report was the item in connection with the River Plate Telephone and Electric Light Company. They had, however, confined their business exclusively to the telephone. That was an affair this Company became committed to when he was not on the Board, but it was in one sense the most fortunate thing this Company had done. They committed themselves to an enterprise in the River Plate of great promise, and one not involving a large amount of original outlay. At the time of assuming this liability they also expected to have the public find the money with which to carry it on, and not unnaturally but most reasonably, particularly as at that time there was a great deal of money forthcoming for electrical business. The Company in question, however, did not come out until the latter part of the ebb time in connection with these enterprises, but the business was so good that the directors of the Consolidated Company, acting to the best of their judgment, and in the interest of the shareholders, supported that Company; and subsequently a further attempt was made to issue capital, with, however, a result very similar to that in the former case—a very small capital subscribed. Meantime it had kept the factory going. The orders coming from the Postmaster-General were practically *nil*, and the material they furnished to the River Plate Company was supplied at very good prices. The telephone business there was almost unique, and this Company had an enormous interest in it. The use of the telephone there in proportion to population was higher than in any other part of the world. He quoted from an official Argentine publication when he stated that the telephone in use in Buenos Ayres represented a ratio of one to every 178 people. That figure represented not only the interest of this Company, but also that of the opposing company, which was neck and neck with them—they had both about the same number of subscribers. That was where a good deal of the Company's money had gone, and "it had gone to a very good place" [laughter]. Well, he wished all the rest of the money was in as good a place; and perhaps it was. The only other outside enterprise the Company had taken—and any one of these was too large for the original capital of the Company if they considered they were going to carry them on themselves — was the Edison-Gower-Bell Telephone Company of Europe, whose business was confined chiefly to the business of telephone exchanges in Lisbon and Oporto. Briefly he might state that the money in that concern was earning very good interest. The capital of the Edison-Gower-Bell Company was altogether out of proportion to the capital in it. Its business was a paying business; there were several hundred subscribers to the exchanges, and they were managed very economically. On the previous day he received a communication from the manager there. He had known for some time that the King of Portugal was anxious to have the telephone extended from town to town, and had been anxious that they should connect Lisbon and Oporto. The communication he had received from the manager stated that a trial had been made the day before the letter was written, with very satisfactory results. There had been a good many changes on the Board of the Consolidated Company, and at the present time the chairman of the Company and one of the directors retired, under the provisions of the Articles of Association. There was not one of the directors who would not have been very glad to resign and give up his position to any one else. They might be able to form some idea of the labours of the Board, contending against the difficulties to which he had alluded; but they did not feel that they could voluntarily offer to go out of office. The consequence was that the names of all the members of the Board were put into a hat, and the names of those drawn out were Sir Julius Vogel and Sir Alexander Armstrong. Sir Julius was in Australia, but they had telegraphed out to know whether they should offer his name for re-election, and he had replied in the affirmative. The report also called attention to the fact that the Board as it stood, including the two who retired, had reached the minimum provided by the Articles of Association. Notice, however, had been given that the names of three gentlemen, members of the Company, would be proposed at that meeting; and he desired to say that he was very glad that there were shareholders who took sufficient interest in the Company to have taken this course. The gentlemen referred to held shares in the Company to an extent which alone entitled them to have a very important voice in the constitution of the directorate, but he was personally unacquainted with any one of them. With regard to the extraordinary general meeting which had been called for that day after the present meeting, he had not told them any of the reasons that had led the Board to make the settlement stated in the accounts as having been made with the River Plate Company, and he would say why he had not done so.

Mr. STOOP rose to order, and stated that notwithstanding that a protest had been sent in against this settlement the chairman had thought fit to announce that a meeting would be held after the present meeting to confirm the action of the Board. He should have thought it would have been more in order if the matter were dealt with at a meeting specially convoked.

The CHAIRMAN said he believed there was no difference between them on this matter, but he thought it was perfectly competent for him to make the remarks he wished to make on the question. He was not going to move the resolution which had been advertised, but was coming to the very question of the protest concerning the proposed settlement. Shortly after the issue of the River Plate Company's report, the Board of the Company received a protest from shareholders demurring to the settlement, and pointing out that in their opinion—he presumed acting on advice—the powers of the directors were not adequate to do what they had done, and that therefore their action was *ultra vires*. It was a matter of some surprise to the directors—not at any one protesting against their views—but that there was any doubt as to the powers of the Board, especially in view of the fact that before the settlement was made it was most anxiously considered. The directors, however, were thankful that someone had pointed out that they were possibly doing something which they had no right to do. No one at the Board had any wish to do anything *ultra vires*, or against the wishes of the shareholders. Under ordinary circumstances they would have called the extraordinary meeting first, and disposed of the matter. As things stood now, when they had asked him questions, he intended to propose the adoption of the report, subject to the adoption of the resolution to be proposed at the extraordinary meeting. He would ask them to elect the directors first, when they would have a Board comprising several gentlemen who had no interest with the Board as a Board, who represented a very large holding in the Company, and whom he believed to be competent in every respect to judge wisely with respect to the resolution to be dealt with at the extraordinary meeting. When they had elected their new Board they would adjourn the meeting, if it were the wish of the meeting that that course should be taken, until the holding of the extraordinary meeting. The reasons which had actuated the Board of this Company in making the settlement with the River Plate Company—which they had stated in the accounts was made subject to the shareholders' approval—were of a nature solely in the interest of this Company. They involved some very peculiar circumstances, but in none of those circumstances was there anything of the nature of a private interest on the part of any member of the Board, or of the Board of the River Plate Company. Unfortunately the directors of the River Plate Company were directors, with one exception, of the Consolidated Company, and there was a provision in the Articles of Association of the Consolidated Company by which it appeared that its directors could not vote on a resolution in which they were interested. The only interest, however, that the directors of the Consolidated Company had in the River Plate Company was that interest which came from their being directors of the Company, and shareholders, only to a small extent. [A VOICE: The directors hold the minimum number of shares in both companies.] He would deal with any question the shareholders might raise after he had finished. He did not give the reasons which had led them to make the settlement, and he desired not to do so; but for no other reason than that he thought it would be most prejudicial to the shareholders' interests that they should be discussed at a public meeting. There was not, however, a single thing which he was not ready to explain to any shareholder or set of shareholders. They must remember that this matter bore on a most valuable asset of the Company, which alone might pull the Company through all its difficulties. He concluded by moving the adoption of the report.

Mr. P. CARNEGY, C.I.E., having seconded the motion,

Mr. STOOP moved an amendment, appointing a committee of shareholders to investigate and report upon the position and affairs of the Company, with full power to call for all books, accounts, documents, &c., belonging to the Company, and adjourning the consideration of the directors' report until after the receipt of the report of the committee; and appointing as the committee, with power to add to their number, Messrs. Henry Grewing (Messrs. Oppenheim and Sons), Arthur Baker (of the Stock Exchange), C. L. W. Fitzgerald (Messrs. F. C. Stoop and Co.),

Digitized by Google

John Taylor, and B. G. B. Howden. It was very important for them that the Company should be well managed, on account of the character of the Articles of Association. He was surprised that any honest man could have been found to establish a company with such Articles. He read Clause 90, as follows, observing that the rest of the Articles were equal to it:—"No director, or intended director, shall be disqualified by his office from contracting with the Company either as vendor or otherwise, nor shall any such contract or any contract or arrangement entered into by or on behalf of the Company with any company, corporation, or partnership of, or in which any director shall be a member or otherwise interested, be voided, nor shall any director so contracting, or being such member or so interested, be liable to account to the Company for any profit realised by any such contract or arrangement by reason only of such director holding that office or of the fiduciary relation thereby established; but no such director shall vote in respect of any such contract or arrangement." He contended that that meant that these Articles opened a wide field for the directors taking as much liberty as they liked with the shareholders' money.

Mr. BUCKINGHAM seconded the amendment, and observed that the Company certainly wanted looking into. He could not help thinking that if the Company were properly handled something could be made out of it. He was not sure that the gentlemen at the Board understood the business. The committee was offered in the most friendly way, and he trusted that the directors would not attempt to oppose it, or something very serious would he feared occur. He hoped the committee would go into the question of what was obtained for the £137,500 which had been paid for goodwill and patent rights [A VOICE: To whom was it paid?], and to whom it was paid.

Mr. W. FORD suggested that before they went further the Board should state what course they would take as to the amendment.

The CHAIRMAN said he would at once accept it on behalf of the directors. It seemed to him that he had himself suggested the same course, "only in another way" [laughter].

The amendment was then put and carried unanimously.

After some discussion on the point,

The CHAIRMAN proposed the re-election of Sir J. Vogel, which was seconded by a SHAREHOLDER, but lost on a show of hands.

Mr. C. L. W. FITZGERALD then proposed and the CHAIRMAN seconded the re-election of Sir A. Armstrong, which was carried.

On the motion of Mr. STOOP, seconded by the CHAIRMAN, Messrs. H. Grewing, A. Baker, and C. L. W. Fitzgerald were elected directors.

It was decided to defer the question of the election of auditors until the committee's report had been received.

The CHAIRMAN then announced that the general meeting stood adjourned.

The SECRETARY next read the notice convening the extraordinary meeting, but

On the motion of Mr. BAKER it was adjourned.

A vote of thanks to the chairman was afterwards passed, and the proceedings then terminated.

River Plate Telephone and Electric Light Company (Limited).

The general meeting of this Company, originally fixed for the 8th inst., and subsequently adjourned to the 29th inst., was further adjourned, pending the report of the committee of shareholders appointed at the meeting of the Consolidated Company, under the circumstances referred to in our report of the proceedings at the meeting of the latter company. It is stated that a further notice will be issued "calling a meeting at the earliest possible moment after the adjourned meeting of the Consolidated Company."

TO BE SOLD BY TENDER, in four lots, pursuant to an order of the Honourable Mr. Justice Pearson made in an action "Pedley v. Rogers and others," with the approbation of the judge, certain ENGINES, Machinery, Dynamos, and other Electrical Appliances and goods, situate at 57, Wellington-road, Barnsbury, in the county of Middlesex. Tenders are to be sent to Mr. Arthur Cooper, of 14, George-street, Mansion House, E.C., the Receiver in the said action, not later than JUNE 2, 1884, when they will be duly considered and be subject to the approval of the Judge at Chambers on Monday, June 16, at twelve. Catalogues and conditions of sale and forms of tender may be had of Messrs. West, King, Adams, and Co., 66, Cannon-street, E.C., Solicitors; of Messrs. Rogers and Chave, 3 and 4, Great Winchester-street-buildings, E.C., Solicitors; of Messrs. Pedley and Bartlett, of 23, Bush-lane, E.C., Solicitors; and of the Receiver. The Property may be viewed on 28th, 29th, and 30th May, 1884.

ELECTRIC LIGHTING.

The METROPOLITAN BOARD OF WORKS is prepared to receive TENDERS for the LIGHTING by ELECTRICITY of the VICTORIA EMBANKMENT and WATERLOO BRIDGE during Three Years from the 1st of July next. The number of lamps to be lighted is fifty, forty being on the Embankment wall, extending from Westminster to Blackfriars, and ten on Waterloo Bridge.

The lamps are required to be lighted during six hours (beginning at sunset) on every day throughout the year.

Persons tendering must state what mode of electric lighting they propose to adopt, and the price per lamp per hour for which they are prepared to undertake what is required.

The person or persons whose Tender may be accepted will be required to enter into a contract for the due fulfilment of the undertaking.

Tenders must be addressed to "The Clerk of the Metropolitan Board of Works, Spring Gardens, S.W.," and be delivered at this office not later than 4 o'clock on THURSDAY, the 12th of June, after which time no Tender will be received.

The Board does not bind itself to accept the lowest or any Tender.

J. E. WAKEFIELD,
Clerk of the Board.

Spring Gardens, S.W.,
22nd May, 1884.

ELECTRICAL ENGINEER, speaking four languages, good experience, good references, seeks engagement. Terms moderate; manufactory preferred. Would give important invention for good situation.—Letters to F. PORTER, Wool Exchange, London.

AN ELECTRICAL ENGINEER or ELECTRICIAN wants a SITUATION either in a Company or as an Assistant to a professor of physics. Has good testimonials.—Apply to R. W., *The Electrician* Office.

TO ELECTRIC LIGHT COMPANIES.—It is proposed to LIGHT Four of the principal Hotels in Manchester from one contiguous centre.—For information and particulars please address to FREDERICK MURGATROYD, 6, John Dalton-street, Manchester.

FOR SALE.—A NUMBER of DIRECT and ALTERNATE CURRENT DYNAMOS and ARC LAMPS, chiefly by Siemens Bros.; little used and newest types; half price.—A. MACKAY, 104, Commercial-street, Dundee.

WANTED.—Two Pairs of MICRO-TELEPHONES and RECEIVERS. Must be of good make, and in first-class working order.—Send price and full particulars to X. Y. Z., care of Editor, this paper.

NOTES.

Cable Interrupted.—The cable between Maranham and Para is interrupted.

Natal.—A committee has been formed at Durban to facilitate postal and telegraphic service between Natal and the Gold Fields.

Brazilian Submarine Telegraph Company.—The traffic receipts of this company for the week ended May 30th amounted to £3,372.

St. George Telephone Company.—Mr. Justice Chitty has appointed Mr. G. Boggis, of 14, St. Swithin's-lane, E.C., official liquidator of this company.

Book Received.—"A Handbook of Electrical Testing," by H. R. Kempe, third edition. Published by Messrs. E. and F. N. Spon, Charing Cross and New York.

Electric Lights for War Vessels.—H.M.S. "Wanderer," Commander Orford Churchill, is being fitted with the electric light prior to her departure for China.

The J. B. Rogers Electric Light Company.—Vice-Chancellor Bacon has appointed Mr. F. G. Painter, of 2, Moorgate-street-buildings, E.C., official liquidator of this company.

The Turner Gas Engine Company.—A petition for the winding up of this company was presented on the 17th ult., and will be heard before Mr. Justice Chitty on the 14th inst.

Cable Repaired.—The West India and Panama Telegraph Company announce that the Key West-Havana cable is now repaired, restoring communication, *viâ* Cuba, to all West Indian stations.

The "Great Eastern."—After all, the "Great Eastern" is not to be turned into a coal hulk. Her late purchasers having failed to complete their contract the huge vessel is again for sale or charter.

Dividend.—The directors of the Brazilian Submarine Telegraph Company have declared an interim dividend of 3s. per share, or 6 per cent. per annum, free of income-tax, for the quarter ending March 31st.

Eastern Extension Telegraph Company.—The traffic receipts of this company for the month of May, 1884, amounted to £35,910, and £32,156 for the corresponding period of 1883, being an increase of £3,754.

Earthquake in Persia.—A violent shock of earthquake occurred on the night of the 18th of May, at the Island of Kishin, near the Persian Gulf. Two hundred persons were killed and many injured. Twelve villages were destroyed.

Western and Brazilian Telegraph Company.—The traffic receipts of this company for the week ending May 30th were £2,632, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

The Chicago Convention.—President Arthur has had a private wire erected between Chicago and White House, Washington, in order that he may keep himself acquainted with the doings of the Republican Convention assembled at Chicago.

The Bennett-Mackay Cable.—A despatch from the "Faraday," dated June 2nd, midnight, states that she has paid out 840 miles of cable from Dover Bay eastwards. She has buoyed the cable, says a Reuter's telegram, and will return to England.

The Soudan.—The latest news from the Soudan reports that the Governor of Dongola is repairing the telegraph wires. The inhabitants are also said to be repairing the wires near Bebbeh, but much progress could not be made, owing to lack of materials.

The Model Telpher Railway.—Professor Fleeming Jenkin's model of his telpher railway can be seen in action at No. 18, Fitzroy-street, W., on Friday afternoons, by members of the Society of Arts and others, on presentation of their visiting cards.

From Suakim.—The correspondent of a daily paper states that Osman Digna has imprisoned forty of his men, who were so scared at the electric light shown from one of Her Majesty's vessels in Suakim Harbour during a recent night attack that they incontinently bolted.

Kelway's Electric Log Syndicate.—A petition for the winding up of this company is to be heard by Mr. Justice Kay on the 13th inst. The company themselves have also decided to wind up voluntarily, and have appointed Mr. E. J. Morris, of Lombard-street, E.C., as liquidator.

Business Notice.—The title of the firm of Clegg and Shaw, insulated wire manufacturers, of the Alexandra Works, Varley-street, Oldham-road, Manchester, has been changed to that of Shaw and Connolly. The firm's representative in London is Mr. R. Applegarth, of 11, Queen Victoria-street, E.C.

Death of Captain Rego.—The death is announced as having taken place on the 22nd of last month, at the age of fifty-nine, of Captain Valentine Evaristo do Rego, for many years director of Portuguese telegraphs. He represented his country at the different telegraph congresses that have been held.

City and Guilds Institute.—In response to the appeal of H.R.H. the Prince of Wales handsome donations towards the General Fund and the Equipment Fund of the Central Institute in Exhibition-road have been promised by the leading City companies, the Fishmongers' Company alone contributing as much as £4,000. It is confidently expected that the sum required will be subscribed.

Communication with the Eddystone Lighthouse.—At the last meeting of the Plymouth Chamber of Commerce a letter was read from Mr. G. F. Rogers offering to prepare plans and estimates for laying a cable to the Eddystone, provided Lloyd's or the Chamber would lend a steam tug free of charge for the purpose. He estimated he could lay and put a cable in working order within six weeks.

South Kensington Mutual Electric Lighting Company.—On Friday week Mr. Justice Kay heard the petition of Mr. W. Burchell, the solicitor of this company, for a winding-up order, on the ground of its inability to pay his bill of costs, which he had applied for in the usual way. The company had been recently formed, but had done no business, although the memorandum of association was framed in the ordinary manner. The object of the company was to light up certain parts of South Kensington by electric lights, but they were wholly unsuccessful.—His lordship made the order applied for.

Fire in an Electric Light Factory.—About noon on Saturday last a fire broke out in the Swan United Electric Light Company's new factory in the Rue des Sarrazins, Lille, France. It commenced in the room where the lamp globes are exhausted, and quickly spread to other portions of the

Digitized by Google

works. Luckily the workpeople had just left for *déjeuner*. The fire rapidly assumed large porportions and attacked the surrounding buildings, which were severely damaged. It was got under about 4:30 p.m. It is estimated that damage to the extent of 500,000fr. has been done. The company were insured for 800,000fr.

CHINA.—The Great Northern Telegraph Company publishes the following list of towns in China which are now connected by telegraph, with the rates per word in each case:—Hong Kong, Shanghai, Foochow, Amoy, and Gutzlaff, 8s. 4d.; Canton, Fattschan, and Ngouchow, 8s. 9d.; Chinkiangpoo, Lanchee, Shiakwan, Chinkiang, Nankin, Soochow, Chining, Ningpoo, Taku, Kiukiang, Nganken, Tientsin, Kiuning, Puching, and Wuhu, 9s. 7d.; Hankow (telegrams addressed "Hankow" are until further notice sent by daily steamer from Kiukiang), 7s. 10d.; Tungchow, 10s.; Pekin (plus postage of 1s. 10d. from Tungchow for each telegram), 10s.

AN ELECTRIC RAILWAY IN SWITZERLAND.—It is proposed to construct an electric railway between the Hotel des Alpes at Chillon and the Hotel de Mont Fleury at Montreux. The difference in altitude of these two points is about 180 metres. Preliminary experiments have already been made. An electric motor placed on the car drives a cog wheel; this wheel gears into a central cogged rail, and in this way the car is made to traverse the ascent. Conductors placed alongside the central rail convey the current from the generator, which is driven by a 5 horse-power locomotive. It is intended to drive the dynamo by water-power for the future.

THE TELEPHONE AND DYNAMITERS.—On the occasion of the recent explosions of dynamite in Scotland-yard and St. James's-square, the police authorities telephoned on the first alarm to Wellington Barracks asking that the Guards should be got under arms at once, and in a very short time an answer came back by the same agency stating that the men were ready for any emergency. If the suggestion thrown out a few months since by a well-known French electrician be adopted, and the microphone utilised at station cloak rooms to detect the ticking of the clockwork of infernal machines, the combination against dynamiters will be complete. What with the telegraph, the telephone, and the microphone, their profession, which has hitherto been by no means free from risks, should become too hazardous to be worth following, despite the "piles" of the "almighty dollar" which are said to be attached to it.

THE BRUSH AND SWAN ACCUMULATOR PATENTS.—In another column we print a decision of considerable interest relating to accumulator patents. The question in dispute was as to who first invented the "perforated or cellular plate for secondary batteries having perforations or cells extending through the plate and the active material or the material to become active packed in said perforations or cells." The litigants in the case were Brush and Swan, and the matter has been before the Examiner of Interferences in the United States Patent Office for the last three years. The result is that priority is adjudged to Swan, Brush having failed to show that he made the invention prior to the filing of Swan's application for a patent. Swan's English and American patents, we may add, belong to the Electrical Power Storage Company, of Great Winchester-street, E.C. A perusal of the case leaves the impression that the patent laws of the United States are peculiar, to say the least of it.

"H" AT OXFORD.—Mr. R. H. M. Bosanquet has determined the mean value of the horizontal component of the earth's magnetism at Oxford. In a paper in this month's *Phil. Mag.* he writes:—"In Gauss's 'Atlas des Erd Magnetismus' there is a table of the magnetic elements for points differing 10° in longitude, and 5° in latitude. Forming the differences appropriate to Oxford, taking its position to be $1\frac{1}{4}$° west and $\frac{1}{4}$° north of Greenwich, and finding the Greenwich quantities from the data in Everett's book of units, I get—

Mean Greenwich value of H for 1884	·18186
Correction deduced from Gauss's differences for Oxford	– ·00227
Value for Oxford thus obtained	·17959
Result of present determination	·18010

It appears, therefore, that the observed result is somewhat nearer the Greenwich value than the indications of Gauss's differences would lead us to suppose."

PRIVATE LIGHTING.—Mr. C. P. Huntington, of Astley Bank, Darwen, Lancashire, has adopted the electric light at his mansion at Astley Bank. An engine house has been erected by Mr. James Pilkington at the rear of the house, in which one of Crossley's gas engines has been fitted. The engine is $3\frac{1}{2}$ horse-power, and drives a Victoria B^2 compound dynamo. The lamps used are Brush 60 volt incandescents, and they are fitted on the existing gas lamps and chandeliers. Three electric lights take the place of six gas lights. The following figures show the way in which the lamps are distributed, viz.:—Drive 4, hall 4, verandahs 6, drawing room 15, dining room 4, reception room 5, billiard room 13, study 1, sitting room 4, nursery 6, house maid's pantry 1, engine house 2, bed rooms 13, landings 8. In Mr. Huntington's bedroom there is a little button, and by pressing his finger upon it he can stop the engine. The verandahs have not before been lighted, as it was believed that gas would have an injurious effect upon the plants, but the use of incandescent lamps in no way injures the vegetation, and produces a very pretty effect. The whole of the work has been successfully carried out by Mr. F. D'A. Goold, electrical engineer, of Manchester.

THE TELEPHONE AND BREAKDOWNS.—"The practical use of telephonic communication was well illustrated in Manchester on Saturday last," says the *Mechanical World* of the 5th inst. "At a large works employing several hundred hands a main shaft, 5in. in diameter, was broken by torsion at a few minutes before closing time. Had not the telephone been available a messenger despatched to the nearest engineering works would have arrived after the men had dispersed and the works had been closed. The telephone being brought into requisition, the manufacturers were enabled to communicate with a firm of engineers two miles away in time to make preparations for repairing the broken shaft, and on Monday morning everything was ready to start at the usual time. It would have been more convenient for the manufacturers to have employed engineers nearer at hand, but unfortunately none were in telephonic communication. Here at least a day's wages was saved for several hundred hands, and a day's stoppage of valuable machinery was prevented by the fact that the works were connected with the Telephonic Exchange. On the other hand, a very profitable piece of work was lost to a firm of engineers who were not so connected."

ELECTRIC LIGHTING AT PLYMOUTH.—The opening of the new promenade pier at Plymouth took place on Thursday, the 29th May, in the presence of a large company. This is the first pier in which the electric light has been used throughout The deck of the pier is lighted by eighteen Brush arc lamps enclosed in hexagonal lanterns, glazed with ribbed glass which,

Digitized by Google

while toning down the glare, materially aids the diffusion of the light. The refreshment rooms, reading rooms, and book stall are lighted by thirty-two incandescent lamps run in groups of eight on the arc current. Two No. 6 Brush dynamos furnish the current, each machine supplying nine arc lamps and sixteen incandescent lamps. The power is supplied by a sixteen-horse Otto gas engine placed under the head of the pier. The effect on Thursday when the lamps were turned on was magnificent, the whole pier being flooded with a soft white light which illuminated a considerable portion of the Hoe, upon which thousands of people had congregated. The pier itself was crowded to its utmost capacity, over 14,000 paying for admission. The work was carried out for the Great Western Electric Light and Power Company by Mr. J. Woolley, the superintendent of their Bristol lighting station. Messrs. Callender supplied the cable, and Messrs. Verity the electroliers.

THE TURIN EXHIBITION.—Our correspondent at Turin writes:—"After long delay, occasioned by the non-arrival of the plant for the establishment of several systems of electric lighting, the electrical section of the Turin Exhibition was opened by the King and Queen of Italy on Tuesday evening, the 27th of May, at nine p.m. Their Majesties entered the magnificently illuminated gallery at the appointed hour, and after saluting the numerous members of the Royal family and the municipal authorities and executive committee there assembled, they commenced their tour round the gallery accompanied by Professor Galileo Ferraris. Their Majesties first entered the space allotted to the Eastern Telegraph Company, and examined minutely Sir William Thomson's 'recorder.' Both the King and the Queen declared themselves astonished at the admirable way in which the instrument worked, and said that they would return another day to examine it more at their leisure. As representative of the 'Eastern' Company the Chevalier Alfred Eggington informed their Majesties of the extended system of cables belonging to the company, and His Majesty highly praised the energy displayed by the company as carriers of such an immense international traffic. After the Royal party had left the building the doors were thrown open to the struggling crowd, which soon filled the vast hall, and was with difficulty persuaded to abandon the dazzling scene even at midnight. The Turin Exhibition is a decided step in advance of that of Milan. It remains now to be seen if Naples in 1886 will improve on the present one."

ELECTRIC LIGHTING AT HULL.—At a recent meeting of the lighting committee of the Hull Corporation the subject of the electric lighting contract with Messrs. Siemens was gone into. The borough engineer laid before the committee the following letter from Messrs. Siemens:—"We are quite willing to let the electric lighting plant remain at Hull on hire after the expiration of the present contract (28th July, 1884), subject to the following conditions:—1. That the plant he handed back to us at the end of the period of hiring in the same condition, fair wear and tear excepted, as it is handed over by us to the corporation at the end of the present contract, unless the plant is purchased by the corporation during or at the expiration of the period of hiring. 2. That the plant is hired for at least one year from the expiration of the present contract, and that after that time either party can give three months' notice to determine the contract. (3). That the corporation pay us a sum of £476 per year in four equal instalments, payable at the end of each three months. In case these conditions are accepted we have no objection to Mr. Melhuish accepting employment under the corporation to take charge of the plant during the period of hiring." The borough engineer expressed the opinion that the terms contained in this letter were favourable, and should be accepted. The committee having discussed the matter, resolved to endorse the borough engineer's opinion, and to recommend the general committee to accept Messrs. Siemens' terms subject to a contract to be entered into and approved by the town clerk. A further resolution was passed retaining the services of Mr. Melhuish at a salary of £250 per annum.

ELECTRIC LIGHTING ON SHIPS.—The steamship "Royal Dane," one of the fleet of steamers owned by the Tyne Steam Shipping Company, has been fitted up with the electric light, and if the new mode of illuminating turns out all that it is expected to do, all the passenger steamers of the company will be fitted up in the same manner. The current is derived from one of Siemens' dynamo machines placed in the engine room, and driven by a 4 horse-power Tangye engine, which can be supplied with the steam from either the main boilers or the donkey-engine boiler. Lights of 20 candle-power each are fixed in the saloon, sleeping berths, and other places, and portable lamps are supplied for the engine room and stoke rooms. A switchboard is placed near the dynamo machine, by means of which the lights can be turned on or out, each light being independent of the others. The machine is driven by rope gearing in groove pulleys; and a sliding foundation is provided for the machine, so that the gearing may be tightened whenever necessary. In addition to the lamps in the cabins, &c., two large portable lamps, each containing six lamps with an illuminating power equal to 50 candles, or equal to 300 candle-power per portable lamp, are provided for lighting the holds, so that the work of loading and unloading may be carried on safely at night time. There are altogether forty-three lights on board the vessel, and the fitting up has been done by Messrs. J. H. Holmes and Co., electric light engineers, Westgate-road, Newcastle. The "Royal Dane" is the first vessel trading from the Tyne which has been fitted up with the electric light.

ATMOSPHERIC ELECTRICITY. — In "The Beiblätter der Physik," Vol. VIII., p. 148, is a paper by Herr Holtz on this subject, of which the following abstract is given in this month's *Phil. Mag.*:—"The author refers to the papers on this subject by W. Siemens, in which no mention is made of him, although he had in 1877 already expressed the opinion that the electricity of storms is perhaps to be attributed to an electrical action of the sun at a distance. Incited by Siemens's memoir to further thought on the matter, he is led to the following view, which materially differs from that of Siemens. The sun, as Zöllner showed, could only act at a distance in case one of the electricities developed in it were dissipated in space. Assuming that the latter is the negative electricity, both the earth and the moon will acquire it. The earth is thereby exposed to the action of positive electricity at a distance from the sun, and the negative action from the moon. In consequence of the former, the surface of the earth must be constantly negatively electrified during the day and positively electrified on the night side. The action of the moon in reference to the side turned towards it and away from it would be similar, not opposite; so that at the time of the new moon there would be an enfeeblement, and at the time of full moon a strengthening of the inductive action. Aqueous vapour, as it forms, takes with it the electricity of the earth, and this is led to the upper regions of the air. If any horizontal layer is electrified even to the smallest extent, the atmosphere in which countless such layers are heaped up may show appreciable phenomena of tension. The greater violence of the storms in equatorial regions is due to the fact that the inductive action is here of course the strongest, and also the

Digitized by Google

evaporation most abundant. The auroræ borealcs are to be explained by the fact that it is preferably the poles at which opposite electricities meet. The difficulty of establishing this hypothesis by experimental observation is increased by the fact that all the causes above mentioned act simultaneously, as well as by the fact that, along with this, secondary inductive actions of the already electrical masses of air come into play. Only in specially constructed buildings and by the aid of special apparatus would it be possible in the course of time to decide this question. The author proposes, therefore, to arrange electrical observatories (that is, special institutions for observing the electricity of storms), which at the same time would lead to a solution of the important astronomical question of the sun's electrical action at a distance."

The Western Electric Company.—The foundation and starting point of this, now one of the largest electrical apparatus manufacturing companies in the United States, or indeed the world, was a small telegraph shop in Cleveland, U.S., and its founders Mr. Enos M. Barton and Professor Elisha Gray. Its career commenced somewhat prior to 1870. In this year, however, these two gentlemen removed their business to Chicago, and in 1872 the Western Electric Manufacturing Company was organised by the consolidation of the above business with that of the Ottawa shop of the Western Union Telegraph Company. The company's first president was General Anson Stager. Since then it has absorbed several other businesses, viz., in 1875, that of George H. Bliss and Company, and that of the Electrical Improvement Company, of Galesburg, Illinois; in 1879 it took over the shop and business of the Western Union Factory in New York; in 1882, that of the Chicago Telegraph Supply Company; that of the Gilliland Electrical Manufacturing Company, of Indianapolis; and that of Charles Williams, jun., of Boston; and at this time the company's name was shortened to that at the head of this note. In a very short time the Boston and New York Works had to be enlarged, and finally the management in Chicago had to erect a huge building near Van Buren-street to accommodate their rapidly developing business, which had outgrown the accommodation of the old premises. The present building has a floor space of over 100,000 square feet, but anticipating that this may not be enough the company have purchased sufficient ground adjoining to admit of another building of the same size being erected. The floors are lighted by 100 arc lamps, which are supplied with current by dynamos on the first floor. The machinery is driven by an engine of 500 horse-power, specially made for the company by Messrs. C. H. Brown and Co., of Fitchburg, Mass.; its driving wheel weighs 25 tons. The manufactures of the company consist of telephonic apparatus, fire alarms, electric light apparatus, telegraph materials, cables, and miscellaneous articles. The company make great quantities of what is known as the Patterson cable, after the inventor, Mr. William R. Patterson. The chief peculiarity of this cable is the method of insulation adopted. Paraffin is heated to a high temperature and then charged with gas under pressure, and thus charged is forced into the lead pipe of the cable about the core of conductors, all openings among the insulated conductors of the core and all spaces remaining between the core and pipe being thus completely filled with paraffin. In cooling, the gas expands as the paraffin shrinks, so that the filling of paraffin takes the form of a solid cake full of small bubbles of gas invisible to the naked eye. The gas thus mixed with the paraffin increases its insulating capacity greatly. It is said that the Patterson cable has an average insulation ten times that of the standard required for gutta percha cables, and is at the same time freer from induction than cables made of gutta percha or similar insulation. About 3,600 miles of conductors of this cable have been made, and it is in general use in the United States.

Electric Lights for Lighthouses.—We have from time to time referred to the experiments now being made at the South Foreland Lighthouses to test the relative capabilities of electricity, gas, and oil for lighthouse purposes. *The Times* of Thursday had a long article giving some additional information on the subject, the essence of which we now extract. The committee entrusted with the experiments consists of the following members of the Trinity House Corporation:—Captain Sydney Webb (Deputy Master of the Corporation), chairman; Captains Nisbet, Weller, Burne, and Vyvyan, Admiral Sir Leopold M'Clintock, and Mr. Inglis, the secretary to the corporation. Mr. Price Edwards, who was the secretary to the previous committee, acts in a similar capacity with regard to the present one. Sir James Douglass, the engineer to the corporation, is advising the committee on points of detail, and the photometric observations are entrusted to Mr. Harold Dixon. Mr. Vernon Harcourt, F.R.S., is watching the experiments on behalf of the Board of Trade. The Corporation of the Trinity House is acting in conjunction with the Scotch and Irish Lighthouse Boards, and the representatives of various foreign Governments are taking an active interest in the experiments. As our readers are aware, the South Foreland Lighthouses have been lighted by arc lamps since 1857, the current being supplied by four Holmes magneto machines (the E.M.F. of which does not exceed 60 volts), driven by a 10 horse-power nominal steam engine, by Hunter and English, another similar engine being kept in reserve. In connection with the present experiments three temporary wooden towers have been constructed in a line landwards, and bearing north-west from the permanent high light. These towers are marked A, B, and C, and are respectively used for the electric, the gas, and the oil light. Tower A is 245 feet from the high light, and tower B 180 feet from A, tower C being the same distance from B. The focal plane of all the towers is 15 feet below that of the electric high light, which is 380 feet above sea level. In the electric arrangements Baron de Meritens' arc lamps and magneto-electric machines are employed. At present there are two of these lamps and two of the machines in place, but another of each is to be added. The lamps are placed one above the other, or superposed, in the tower. The carbons used in them are compound—that is, they are made up of a number of small carbon rods of square section. "The carbons in use at the time of our visit," we are now quoting from *The Times*, "were 1½in. square, and were composed of 49 small square rods, but since then the new Berlin cored carbons of Messrs. Siemens have been employed. The two machines for producing the current are placed in the engine-house with the others, and, as we have stated, are driven by the same engine as the Holmes machines. Each of the De Meritens machines is arranged for working at 1-5th, 2-5ths, 3-5ths, and at full power, the estimated intensity of the light from each machine at those powers being respectively 6,000, 12,000, 18,000, and 30,000 candles. The machines can either be worked singly or coupled up. Like the Holmes machines, those of De Meritens produce a low tension current, and are found to be very reliable in operation and inexpensive in maintenance. The arrangements for illuminating tower B consist of a small gasworks erected by Mr. J. R. Wigham, of Dublin, whose burners are used in the tower, his system having been adopted for lighthouses on the Irish coast. The gas-producing apparatus consists of a small retort house fitted with two benches of three retorts, the necessary purifiers,

Digitized by Google

and a holder capable of containing 4,500 cubic feet of gas. The gas is passed through a meter placed outside the tower to the burners within it, which are four in number. Each burner is composed of a series of concentric rings of jets, and the light can be started with a *minimum* power of 28 jets, and increased by gradations of 20 jets up to 108 jets, the full power of each burner, at which it develops 3,000 candle-power. There are four of these burners superposed, and they can be used either singly or together. In tower C oil lights are used, and these are produced by means of burners of the recognised Trinity House pattern. The burners at present in use have six concentric wicks, each burner developing 720 candle-power; but Sir James Douglass is preparing another burner of much higher power, having seven wicks, which will shortly be tried. The burners are arranged in three stages, and either a uniform, a biform, or a triform light can be exhibited as required. The burners are in duplicate on each stage, and by an ingenious arrangement the first lamp can be shunted out of position if necessary, and the second one lighted and shunted into its place without any appreciable loss of time. Such are the arrangements for producing the various lights. For testing them carefully elaborated arrangements have been made. An overland route has been laid down as a line of observation for a distance of 2½ miles from the towers in the direction of Deal, and stakes have been driven at every 100 feet. At half a mile from the towers on this route is hut No. 1 for taking photometric observations, and this is more particularly intended for fog work. At 1¼ mile we come upon hut No. 2, which is likewise fitted with photometric apparatus. At the limit of the range is a third hut, each hut being conveniently fitted up for the residence of the official in charge. Upon the occasion of our recent visit splendid lights of varying intensities were produced at night by each of the three systems under trial. The preliminary photometric observations appear to indicate that the electric light in comparison with either the gas or the oil light is as the sun is to a candle."

COLLIERIES AND LIGHTNING.—Writing in the *Colliery Guardian*, Col. Parnell says:—"I now come to another and separate class of terrestrial electrical discharges, and these are what are known as 'return strokes.' A practice originating in the last century with Lord Mahon of designating by this appellation lightning strokes whose force in an upward direction was too palpable to be gainsaid has to some extent grown up. Taking for granted (though on no ground, either of natural or of laboratory experience) that an ordinary lightning stroke was necessarily downwards, Mahon and other philosophers concluded that these undeniable upward strokes were a kind of *lusus naturæ*, to which 'return' (or 'returning') was an epithet of scientific suitability. As a rule, however, in these days text-books recognise the real nature of the class of discharge I am now referring to as being 'induced' electrical discharges, and with this explanation my researches enable me thoroughly to coincide. If in a system of two adjacent electrical condensers a plate of one condenser becomes discharged by means of explosion with a plate of the other condenser, so much of the charges on each of the two undischarged plates of the system as was due to the induction of the discharged plates respectively disappears, or returns to the complementary power or agency whence the act of induction had separated it. This action of return, or recombination, or disappearance, constitutes what is called a 'return stroke,' or 'induced discharge,' and its nature is similar to that of a powerful instantaneous electrical current. These return strokes occur, therefore, near the scenes of actual explosions; and here it may be mentioned that lightning-strokes (or thunderbolts) are not the only kind of explosions liable to occur in connection with terrestrial electricity. There is another class known as 'cloud explosions.' These are explosions between two detached clouds, which may have formed with each other an electrical condenser. Most of the lightning we see in the heavens during a thunderstorm is due to these cloud explosions; and lightning due to strokes between the clouds and the earth (or thunderbolts) is (fortunately for us) much more rare. Now 'return strokes' may be occasioned by induction from either lightning strokes proper or from cloud explosion strokes, and they are constantly manifested under particular conditions during thunderstorms. Their manifestations are chiefly of two kinds—viz., shocks to human beings (seldom to animals) and currents (to use the ordinary convenient nomenclature) on long lengths of more or less insulated metal. The former manifestations are (so far as I am aware) never caused except by lightning strokes proper, but the latter are caused by both kinds of explosion, and during the course of an ordinary thunderstorm are seldom absent from lines of telegraph wires. Much inconvenience is often thereby occasioned, but little danger is ever experienced, since by means of ingenious electro-mechanical arrangements the instruments can generally be safeguarded from the effects of these abnormal intrusive currents. But in our every day commercial practice are there no other long lines of metal equally exposed in a physical sense to the operations of these return strokes? Railway metals will at once occur to most of us. Quite so. And now is there any application of these rail or tram metals along which, unlike the case of ordinary railways, if powerful currents were to pass, conditions of practical interest (the action of powerful currents under certain circumstances being borne in remembrance) might be set up? Yes, unquestionably there is; and the subject forms the very kernel of my present communication. In the tram rails laid along the dry workings of coal mines exist, I believe, elements fraught with considerable practical interest to the colliery owner and (though in a far more intense degree) to the colliery pitman. The instances I am about to adduce will demonstrate to a certainty that these return strokes or induced currents have occurred at the rails in the workings of coal mines. For they have unmistakably manifested their presence by that fearfully dangerous exhibition of flashes, or sparks, which all electrical experience shows is an accompaniment of a powerful electrical current wherever in its passage along the metals that conduct it (and virtually cause it) slight gaps exist in these metals. The sparks and lights that have been seen in coal workings clearly prove that these small gaps do exist in the long lines of rail that permeate them, even if ocular examination should not (as I am afraid that it invariably would) testify to the same fact. Incidental to coal mines there are other metals, such as the long wire rope guides in the shafts, and the flat sheets, engines and other metals near the bottoms of these shafts; but I lay less stress on these pit metals, since I understand that no explosion of 'firedamp' could well be caused by any light or spark that might occur near the foot of a shaft; and that it is in the workings alone that any practical danger from sparks could occur. For the same reason I do not think that even if an actual lightning stroke should occur within a shaft—and so far as the underground portions of an ordinary colliery in Great Britain are concerned I cannot well conceive that such a stroke could possibly occur in the workings—any danger of explosion of firedamp need be apprehended. I have purposely placed the foregoing sentence in the conditional mood, for, so far as I am aware, no undoubted case of such a stroke within a shaft has yet taken place in any country."

ELECTRO-CHEMISTRY.—Inorganic.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 7.)

According to Becquerel, copper and iron become tinned by immersion in contact with zinc in a dilute solution of the double chloride of tin and sodium at 160° F., but are not tinned by simple immersion alone in that liquid (*The Chemist*, Vol. V., p. 408). For coating iron with tin by immersion in a liquid in contact with zinc Roseleur recommends a solution prepared thus:—Take equal weights of stannous chloride, cream of tartar, and water. Dissolve the chloride in one-third of the cold water, warm the other portion of water and dissolve the cream of tartar in it, and mix the solutions; the mixture is clear and has an acid reaction. And a second solution, composed of six parts of crystal, or four of fused stannous chloride, and 60 of pyrophosphate of potassium or sodium, dissolved in 2,000 parts of distilled water. The size of the zinc should be about $\frac{1}{16}$ that of the iron. The deposition occupies several hours. When the solution becomes weak, equal weights of the pyrophosphate and fused chloride are added.

M. Heeren coats iron with tin by immersing it during two hours, in contact with zinc, in a solution of two parts of tartaric acid, three of stannous chloride, and three of caustic soda, and 100 of water (*Jour. Chem. Soc.*, Vol. XIII., p. 672). Stolba uses a solution of 5 to 10 parts of stannous chloride dissolved in 100 of water, and a very minute amount of cream of tartar added. The metal to be coated is wetted with the solution whilst in contact with particles of zinc spread over its surface (*Chem. News*, Vol. XXIII., p. 21). Brass and copper acquire a coating of tin if placed in contact with that metal in a boiling hot saturated solution of cream of tartar.

By means of the single cell process F. Weil coats copper with tin in a solution of a salt of tin in strong caustic potash or soda. A porous cell, containing a solution of the potash or soda, is placed in the bath, a piece of zinc immersed in it, the copper immersed in the hot tinning liquid, and the two metals connected together by a wire. The deposit is pure tin, and may be obtained of any thickness. To revive the inner liquid, precipitate the dissolved zinc from it by addition of solution of sulphide of sodium. (*Chem. News*, Vol. XIII., p. 2.)

By means of a separate current, fused stannous chloride yields tin at the cathode, whilst vapour of stannic chloride escapes at the anode (Faraday). He found by experiment that the proportion by weight of tin deposited from fused stannous chloride, and of water decomposed by the same current was as 117·16 to 18 (Watts's "Dictionary of Chemistry," Vol. II., p. 439). Iron may be coated with a beautiful white deposit of tin by making it the cathode in a solution of stannate of potash; but the solution is gradually decomposed by contact with the atmosphere, and deposits peroxide of tin.

Various solutions yield tin by this method. Roseleur's is composed of six parts of crystals of stannous chloride, and 50 of pyrophosphate of sodium, dissolved in 5,000 parts of distilled water, the two salts being dissolved in separate portions of the water, and the solutions mixed, and then stirred till clear. It requires a large anode and a strong current. For various other electrolytic mixtures containing stannous chloride and other ingredients *see* "The Art of Electro-Metallurgy," Longman's "Text Books of Science," pp. 270-272.

Anhydrous stannic chloride did not conduct a current from 8,040 cells of W. de la Rue's chloride of silver battery. (Bleekrode, *Proceedings* Roy. Soc., Vol. XXV., p. 325.)

Separation of Alloys of Copper and Tin.—Iron is said to acquire a deposit of bronze by simple immersion in a solution of 4 to 5 parts of cupric sulphate, 4 to 5 of crystallised stannous chloride, and 100 of water.

For depositing bronze by a separate current, Salzede used a solution composed of cupric chloride, stannous chloride, nitrate of ammonium, and potassic carbonate and cyanide, dissolved in water. For the same purpose Newton used one composed of the tartrates of copper, tin, and potassium.

Formation of Crystals of Tin by Electrolysis.—The crystallisation of tin is a phenomenon conspicuously striking under some conditions in a solution of stannous chloride. The crystals of tin formed upon the cathode increase so rapidly in length as to grow across the solution, and touch the positive pole in a few minutes. And if the solution and current are strong, and the cathode small, quite a mass of crystals will soon fill the liquid, and converge towards the anode. If the anode be drawn farther away in the solution the crystals follow it. The largest crystals are produced by slow action; to produce them a platinum capsule is covered with an outer coating of wax, leaving the bottom uncovered, and then set upon a plate of amalgamated zinc in a porcelain vessel. The capsule is then filled completely with a dilute and not too acid solution of stannous chloride, whilst the outer vessel is filled with water (containing one twentieth its bulk of hydrochloric acid) up to such a height that the two liquids come into mutual contact. The electric current generated reduces the salt of tin, and in a few days the crystals upon the interior of the capsule are well developed, and should be washed with water and dried quickly. (F. Stolba, *Chem. News*, Vol. XXX., p. 177).

For the electrolytic analysis of compounds of tin see *Chem. News*, Vol. XLVI., p. 106. Also Watts's "Dictionary of Chemistry," Vol. VI., p. 676, *Jour. Chem. Soc.*, Vol. XL., 1881, p. 1,081, Vol. XLII., 1882, p. 1,320.

Separation of Cadmium.—Cd. Electro-chemical equivalent $=\frac{112}{2}=56$. A dyad cation. Sodium amalgam decomposes a solution of a salt of cadmium, and forms cadmium amalgam (Böttger). From a solution of the chloride, magnesium deposits, with strong action, a mixture of cadmium and an oxychloride of the same metal (Commaille, *Chem. News*, Vol. XIV., p. 188). I have found that crystals of silicon heated with cadmic fluoride set free cadmium.

According to Raoult, gold or copper in contact with cadmium in a concentrated and boiling solution of cadmium sulphate or chloride, decomposes these salts, and quickly deposits a white, brilliant, and firmly adherent but thin film of cadmium upon the gold or copper, even when the solution is not acidulated and no hydrogen evolved. The experiment does not succeed with the nitrate. But gold in contact with iron, nickel, antimony, lead, copper, or silver, in cold or boiling acid or neutral solutions of salts of cadmium, receives no such deposit (*Chem. News*, Vol. XXVI., p. 240; Vol. XXVII., p. 59; *Jour. Chem. Soc.*, Vol. XI., p. 464).

By means of a separate current a spongy deposit of cadmium is obtained from its chloride solution to which a few drops of sulphuric acid have been added. Cadmium ammonio chloride gives a grey non-adherent deposit, chlorine being evolved. A similar deposit was obtained from cadmium calcium chloride. Cadmium bromide, acidulated with weak sulphuric acid, gives a coherent mass, susceptible of polish. If an iron wire be used as the cathode, and a copper one as the anode, the cadmium is deposited in long brilliant needles. A good result is also obtained with cadmium ammonio bromide. Cadmium ammonium iodide yields a spongy mass. The sulphate gives a coherent deposit capable of receiving a fine polish. A non-coherent deposit was obtained from the double sulphate of cadmium and ammonium (A. Bertrand, *Jour. Chem. Soc.*, 1877, Part I., p. 161). Russell and Woolrich deposited cadmium by the electrolysis of a solution composed of cadmic carbonate dissolved in aqueous potassic cyanide, with free cyanide added, and using the liquid at about 100° F. with a cadmium anode.

For the electrolytic analysis of compounds of cadmium see *Jour. Chem. Soc.*, 1877, Part I, p. 340; also F. Beilstein, Vol. XXXVI., 1879, pp. 276 and 746; Vol. XL., 1881, p. 1,081; Vol. XLII., 1882, p. 896. Watts's "Dictionary of Chemistry," Vol. VII., pp. 229 and 790 (E. J. Smith). *Chem. News*, Vol. XXXIX., p. 185; ditto (Beilstein and Jamain), Vol. XL., p. 109; Vol. XLIII. (E. Smith), p. 61; and V. Francken, Vol. XLVI., p. 106. *Jour. Chem. Soc.*, Vol. XLII., 1882, p. 1,320.

ON MECHANICAL DYNAMOMETERS.

BY GISBERT KAPP.

(CONTINUED FROM PAGE 9.)

A principal aim in designing a dynamometer should always be to have the most direct connection possible between power and resistance, that is between the twisting moment transmittent and the force by which this is measured. The more simple the apparatus used for balancing these two forces against each other the less liability will there be of accidental errors being introduced into the measurements. An instrument fulfilling this condition to a remarkable degree is the energy meter invented by Professor Cyrus F. Brackett, of the College of New Jersey, Princeton, U.S. It has been designed for the express purpose of testing dynamo or magneto machines, and is therefore of considerable importance to the electrical engineer. Tests of that kind can be made with two distinct objects in view. The commercial man does not concern himself about the question how much power is wasted in journal friction, air resistance, heating of the iron parts, and so on, but merely asks for the ratio between horse-power put into the belt and electrical horse-power received at the terminals of the machine; whilst the scientist, on the other hand, being more interested in the purely electrical problem, wishes to eliminate from his experiments all those mechanical resistances which have nothing to do with the actual conversion of mechanical into electrical energy. To satisfy both requirements, Professor Brackett has made two modifications of his energy meter. The principle is the same in either, and consists in measuring the twisting moment or torque which a revolving armature traversed by a current imparts to its field-magnets or other support. The twisting moment imparted to the field-magnets multiplied with the speed of the armature is a correct measure for the mechanical energy which is being transformed into electrical energy, just as the load on a Prony brake multiplied with the speed of the pulley is a correct measure for the mechanical energy which, by the medium of friction, is being transformed into heat or used for producing abrasion of the brake blocks. That this is really the case follows also from the consideration that in all mechanical processes action and reaction must balance each other, and that the torque necessary to prevent the field-magnets from revolving must exactly equal the torque which keeps the armature spinning round. The electrical energy thus produced in exchange for the mechanical energy apparently vanishing is, however, not entirely available in the shape of current and potential. Part of it is lost in magnetic friction, producing heating of the iron in field-magnets and armature, part goes in heating the coils or sparking at the brushes and so on, leaving only a portion of the total energy available at the terminals of the machine. If we now accurately measure the mechanical energy which keeps the armature revolving, and compare with it the electrical energy derived from the terminals of the machine, we obtain the efficiency of conversion. This can be done by the aid of Professor Brackett's energy meter, shown in Figs. 31 and 32 in front and side elevation, as applied to a Weston machine. The apparatus consists of a base plate O, upon which are mounted the bearings D D, supporting the shaft of the armature, and the standards S S, supporting on knife edges K K a crossbeam, G, to which the field-magnets are bolted. In this manner the armature is carried independently from its field-magnets, and neither the friction in the journals H H, nor the friction of the brushes B B, can have any effect on them. Care is taken to bring the knife edges exactly in line with the centre of the shaft, so that the armature remains central in the bore of the pole pieces, even if the field-magnets oscillate through a small angle. A movable weight, W, placed on a graduated bar, X, serves to counteract the tendency of the field-magnets to be carried round by the movement of the armature, and another movable weight (not shown in the drawing) is used to bring the centre of gravity a small distance below the knife edges if the magnets are horizontal and the weight W stands at zero. If the machine is at work, this weight, W, must be shifted out on the graduated yard until the field-magnets are, so to speak, kept floating between the two opposing forces. The energy thus measured is exactly that which is effective in producing the current, with the exception of a very small amount due to the friction of air against the faces of the pole pieces. This, however, can experimentally be determined, and then deducted from the total measurement. No allowance whatever need be made for loss in friction at the brushes, bearings, or other parts of the machine. This is what we desire in a scientific investigation of dynamo or magneto machines; but for commercial purposes we require a dynamometer which will take all the various sources of loss into account, and such

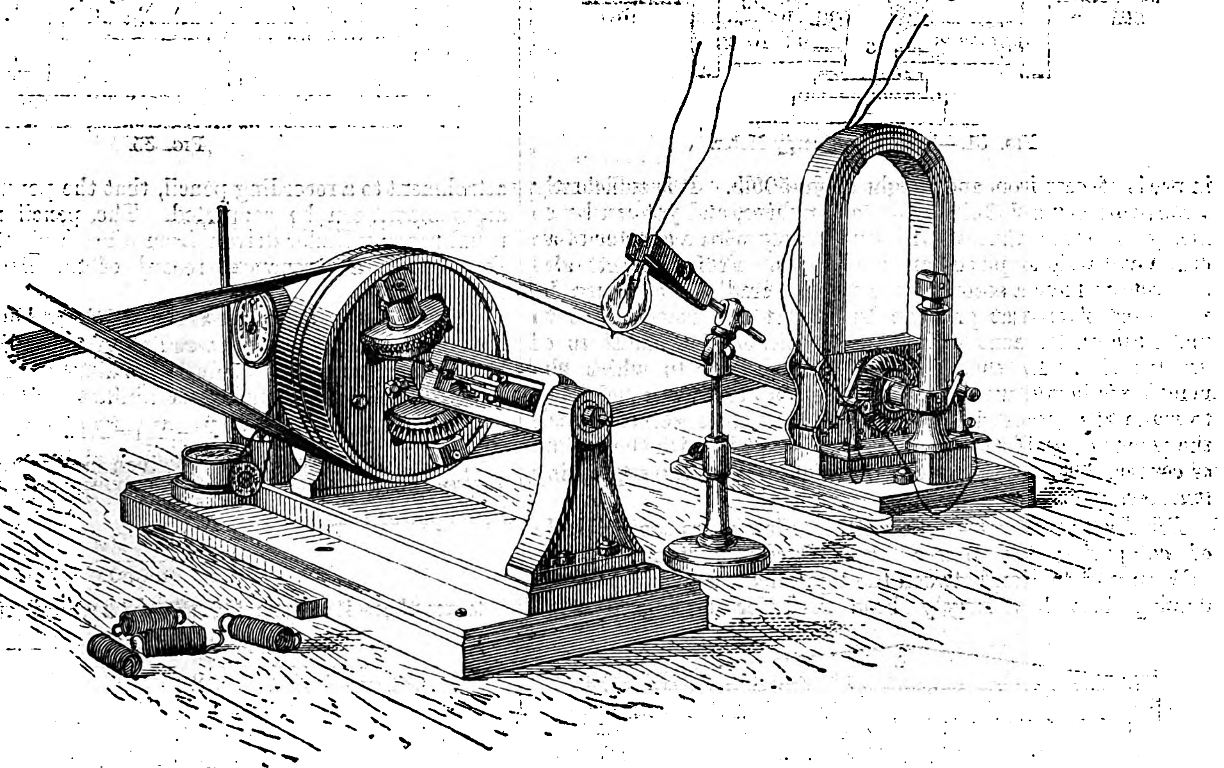

FIG. 30.—Smith's Dynamometer. A description of this machine will be found on p. 9, *ante*.

Digitized by Google

an instrument is made by placing the machine upon a cradle, which can oscillate round centres in line with the centre of the shaft. This arrangement is shown in Fig. 33, where C C is the cradle or platform upon which is bolted the dynamo to be tested; K are frames joined to the cradle on either side of the dynamo, and provided with hardened cylindrical steel pins, as shown, which rest on steel plates supported on the beam *s*. A movable balance weight, B, serves to bring the centre of gravity within a short distance below the point of support, and the weight W indicates by its position on the steel-yard what twisting couple is required to counterbalance the torque transmitted by the belt. The author has been informed by Prof. Brackett that this device is in successful operation at the Stevens Institute in Hoboken, New Jersey. The cradle there

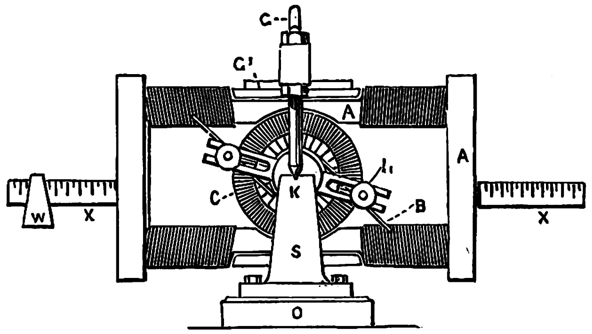

Fig. 31.—Brackett's Energy Meter.

in use is of cast iron, and weighs about 500lb. It is sufficiently strong to carry a 200-light Weston machine, and yet can be so nicely balanced that it will turn freely with a quarter of an ounce overweight placed on either side. Prof. Brackett also suggests to have a second floor to the cradle, which can be raised or lowered at pleasure by means of screws, so as to make the instrument universally applicable for machines of various size. In each case the second floor to which the machine is bolted would have to be set up to such a height as to make the geometrical axis of the armature coincide with the points of oscillation of the cradle—that is, with the points of contact between the steel trunnions and their supporting surfaces.

Belt Dynamometers.—Within the last few years the principle of computing the power transmitted by measuring the difference of tension between the tight and the slack side of a driving belt has largely been used for testing dynamo

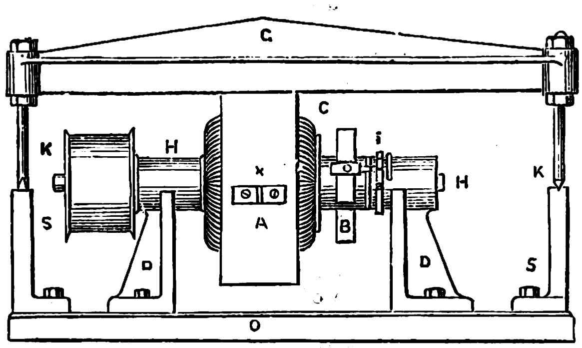

Fig. 32.—Brackett's Energy Meter.

machines. The invention of this form of transmission dynamometer is by no means new, having already been described in 1858 by the late Mr. Froude in a paper brought before the Institution of Mechanical Engineers; but its modification, due to Hefner von Alteneck, which was used in the competitive trials at the electrical exhibitions of Paris, Munich, and Vienna, is of comparatively recent date. We will describe Froude's original instrument first, and then pass on to some of its modifications. In Fig. 34 A is a pulley driven from the prime mover, and D is a pulley either mounted on the axle of the machine to be tested, or connected to it by belt or other gearing. Both these pulleys are supported by fixed bearings. B and C are two other pulleys mounted in roller bearings on either side of a lever, which is pivoted in F and stands approximately at a right angle to the centre line A D. The three pulleys, B, C, and D are equal in size, and the distance between the centres of B and C is equal to twice the diameter of these pulleys plus the double thickness of the belt, which is taken round the four pulleys, as shown in the drawing. The large pulley is about three times the diamater of the small ones, in order that the pull of the belt may be as nearly as possible vertical to the lever. It will be clear that if A be driven in the direction of the arrow, there will be a tendency of the upper part of the lever to be displaced to the left. This tendency is counteracted by a spring, P, and it is by observing the elongation of the spring, as shown by a cord-

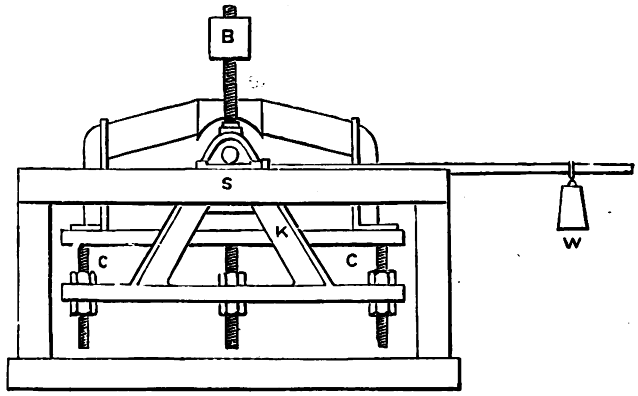

Fig. 33.

attachment to a recording pencil, that the power transmitted at any moment can be computed. The pencil moves over the usual paper cylinder driven from the shaft of pulley D, and thus leaves a permanent record of the horse-power transmitted.

Let T_1 be the tension on the driving side of the belt, T_2 that on the slack side, r the radius of the small pulleys plus half the thickness of the belt, R the distance of the spring from the fulcrum F, and P the tension in the spring; then

$$4\,r\,(T_1 - T_2) = P\,R.$$

If n be the speed of pulley D given in revolutions per minute, and P and R be given respectively in lbs. and feet, we find the horse-power transmitted

$$H.P. = \frac{\pi\,R\,P\,n}{66{,}000}.$$

Since there is a little difficulty in determining the pull of a

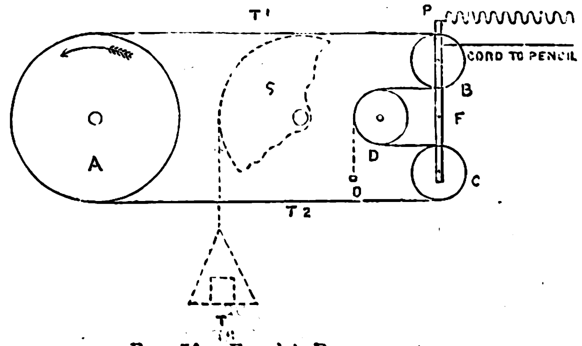

Fig. 34.—Froude's Dynamometer.

spring, Mr. Froude eliminated this quantity by a system of direct calibration, which was done in the following way:—The belt was removed, and another belt was attached to a fixed point *o*, and taken round D, B, and over a loose pulley, S, as shown in dotted lines. To the end of the belt known weights, T, were applied, and the elongation of the spring observed.

Since $2\,r\,T = P\,R$, and since also the elongation of the spring, that is the displacement of the pencil along the recording drum, is proportional to P, we can find by this experiment the scale to which the diagram is drawn. Let $P = a\,\mu$, where a is the displacement of the pencil producing the ordinates on our curve of horse-power transmitted, and μ a measure for the elastic power of the spring, then we find

$$2\,r\,T = R\,a\,\mu,$$

Digitized by Google

and if, as is usual, $R = 2r$ (that is, the point of attachment of the spring is in line with the axis of wheel B), we have

$$\mu = \frac{T}{a}.$$

Having thus found how many pounds circumferential strain transmitted are represented by every inch displacement of the pencil from its zero position, we obtain the formula for the horse-power.

$$H.P. = \frac{\pi r a \mu n}{33{,}000}.$$

The spring used should be so proportioned that, even when transmitting a maximum of power, the lever is not pulled out too far from the vertical, or otherwise the formula becomes incorrect. Care should also be taken to have a very pliable driving band, either endless or at least so jointed as to present a smooth surface on the inside and outside.

ELECTRICITY AND LIGHT.—II.

BY JOHN T. SPRAGUE.

(CONTINUED FROM PAGE 8.)

11. *Energy is tranmissible in various methods.* These methods are of different orders, and may be classified in different manners. The primary distinction is that which gives the leading difference between mechanical and chemical work, *molar* and *molecular*, the action of masses of matter dependent upon pure weight, and the action of the ultimate particles of matter dependent upon the varying properties of each kind of matter. Intermediate between these, and partaking of the nature of both, is the undulatory action of fluid masses. The cricket ball gives us the simplest illustration of purely molar transmission of energy, and probably the simplest concrete view of molecular transmission may be found in a row of billiard balls in contact with each other. If another ball be caused to strike the first of such a row in the true line it comes to rest, while the most distant ball of the row takes up the motion in its place. The intermediate balls remain undisturbed; yet it is evident that each one of them has received and transmitted the energy of the motion. We know that it has done so by means of its elasticity; but if we consider each ball to represent *a molecule*, we may see that each of them must undergo a modification of structure and of properties in the act of transmission. This change is an axial one, involving a condensation and expansion, and it may be so looked at in our imagination (that is our realising or picture-forming capacity) as to enable us to conceive some definite idea of the actions which may occur in those infinitesimal molecules which are altogether beyond the reach of our observation.

12. *Polarity* is an axial difference of properties, and this successive series of condensations and expansions may be regarded either as a *linear undulation*, such as we have to deal with in the transmission of sound, or we may see in it a rough illustration of one form of polarity, and in the row of balls we may see a picture of a *polarised chain of molecules* along which energy is transmitted.

13. *Force and energy*, words which till of late years were used indifferently in the sense of power, are now clearly differentiated, so that force expresses *causes*, while energy expresses *results*, work, or work capacity. But in the usual treatment of this subject this distinction is so strongly pressed that a deeper truth is in danger of being overlooked. For *mathematical purposes* the distinction is essential, and it is permissible, therefore, to treat "force" as a real existence. For *physical purposes* it is equally important to understand that "force" is little more than an abstract symbol—that almost everything which we call a force is really an expression or action of energy. Gravitation, cohesion, and other attractive forces do really appear to have a true existence in nature—to be specific properties of matter. Nevertheless there are abundant evidences that the day may come when it will be seen that their true causes lie in a capacity of matter to absorb energy, and that they are simply a result of and an evidence of the presence of this energy.

14. *Heat, light*, and other agencies which used to be regarded as essential forces, and to explain which specific fluids were invented, are now universally admitted to be such evidences and actions of energy, and the conception of electricity is fast undergoing the same transformation. But it is in mechanics that we may find the clearest evidence that what the mathematician calls "a force" is merely a convenient expression for the powers conferred on matter by a charge of energy.

15. *Energy developing a force*, and in turn reproduced by that force, is clearly illustrated by our row of billiard balls. A force is defined as an agency which can produce or change motion, or which can set up a stress, pressure, or tension. So every mechanical action, such as that of the bat upon the cricket ball, can be expressed in terms of force, while it is evident that this force merely expresses the momentary embodiment of the energy charged at the instant upon the bat. This is what I mean by an expression which has often been objected to, that the unit of force and the unit of energy, say the dyne and the erg, are the same value. The dyne is a force capable of doing one erg of work per second, and that force of one dyne merely expresses the fact that the agency which exerts it has a supply or store of energy so connected to it as to be capable of being expended at the rate of one erg per second; it exists, not by itself, but simply as a consequence of this supply of energy. This fundamental fact is not obvious, because though the unit conditions are equal, they vary in different ratios under all other conditions, as a consequence of the system of expression and of the mode in which energy is stored. This is the essence of the long-sustained conflict of the contact and chemical theories of the galvanic battery; the imaginary *contact force* is merely the evidence of and the expression of the *energy stored in the chemical affinities*, just as an equal force may be developed by means of a corresponding supply of energy, by aid of friction, magnetism, heat, and other molecular actions.

16. *Radiant and linear propagation* afford another classification of energy, as also of various "forces" or modes of energy. A little examination may, however, show that there is little real distinction between the two modes of transmission, that they are, in fact, simple consequences of the single or dual origin of the action. *Radiant forces* are those in which energy streams from a single point. Such are heat and light. *Linear forces* are in fact *polar forces*, resulting from energy acting axially in each direction in the molecules of matter. This is the case with electricity and its allied force magnetism. A little study of the subject from this aspect will be found profitable, and it can be followed through very simple and familiar illustrations.

17. *Radiant undulatory transmission* is seen when we drop a stone into a pool of water. The stone carries a definite quantity of energy, on the same principles as the cricket ball (Sec. 4), and it may be regarded as a store of energy which on being imparted to the water develops therein a force acting from the centre (Sec. 15), the degree of such force, as an expression, depending upon the relations of the quantity of energy and the size of the pond, that is upon the conditions to which the energy can be at once transferred. Reverting to the line of billiard balls, it may be seen that if, instead of a single one terminating the row, there were two placed on a line at right angles to the row, the motion would be divided between these two; or carrying this idea back we may see that if, instead of a single row, at each stage an increased number were placed in contact, the impulse given to the single ball would be distributed over the growing number of contacts, and would finally act, though at each stage with diminished power, upon the whole of the exterior rows.

Such a series would in fact be a part of a circle, and the successive rows of balls, in each of which an act of contraction and expansion occurs, would correspond to the circular waves which would be formed in the pond around the fallen stone, and which would transmit the energy from that stone to the

Digitized by Google

borders of the pond, thence to be reflected and distributed till, at last wholly lost as visible motion and converted into heat.

18. Replace the energy of the falling stone by some continuous action, such as the plunger of a pump alternately lifting and lowering a bulk of water, so that each action produces a wave round it, we have the analogue of any continuous source of energy, and the explanation of the mode in which that energy represents a force whence radiant energy is transmitted. The conditions correspond to those of a large metal plate heated by a flame at the centre, from whence the heat travels by conduction in a series of circles of lower and lower intensity. As precisely the same principles apply to a sphere, we have also the analogue of a centre of combustion diffusing radiant energy as heat and light, or of a musical instrument giving out sound. The special importance of this illustration is that it offers us two distinct views of the nature of radiant energy, or rather of its mode of propagation, according as it occurs in straight lines such as correspond to the ordinary idea of *a ray*, or as it proceeds in constantly enlarging spheres of correspondingly lowered intensity.

19. *Wave action*, or undulatory motion, involves the transfer of energy from particle to particle, as in the case of the balls (Sec. 11), these particles simply moving to and fro, without actual change of the average position, against a force or resistance internal or external, as contrasted with the direct motion of a mass of matter conveying energy. If a cord loosely fastened at each end is strongly jerked, the energy is propagated in wave form to the distant end, and this action will explain the origin and principle of wave transmission of energy. Let one end be held in the hand and jerked downward; then the slack of the rope is strained and a short length of it pulled out of the normal curve until the stress set up on the rope balances the energy of the jerk, and reverses the direction of the motion. The object of this illustration is to show that, even in the solid continuous rope, energy is transferred from particle to particle, just as in water or air. Each section of the flexible and loose rope acts, in fact, just as do the adjoining molecules of water pressed together by external forces. Each of these sections corresponds to the swinging pendulum, which is the element of wave action.

20. *The pendulum* being at rest is lifted, that is to say it is charged with energy—potential energy or energy of position. When allowed to fall it does no work (ignoring air and other friction), and consequently it rises to exactly the height where this *charge of energy* is equivalent to the *force of* attraction between the earth and the pendulum weight; in fact we may conceive that this force of attraction is now actually the creature of the energy which has been expended in lifting the weight, as the force of pressure in a steam engine is the creature of the energy charged on the molecules of water. This potential energy seeking to become kinetic or free draws the weight down, and so we have the regular rise and fall of balance between these two actions as long as no energy can become free, that is as long as no external work is done.

21. *The wave motion in the pool of water* is generated in the same manner. The falling stone or moving piston presses upon a particle of water, which transmits the energy to its neighbours all around, moving them in the only direction in which they are free to move; that is it raises them against the force of gravitation, and so transfers to them the original energy applied. These particles correspond to the displaced portion of the rope, and form a similar slope; but, all being free and movable upon each other, each molecule of water acts like a pendulum weight, and falls, transmitting its energy to its neighbours while pushing them aside. As long as the free rise and fall goes on without doing work (except of course in the mutual friction which ultimately absorbs the total energy, as in the actual pendulum) the undulations will continue to be maintained, the length of the waves—that is the distance between successive crests—and also the height of the waves or amplitude of undulation depending upon the quantity of energy, the mode of its application, and the material in which the undulations are generated.

THE DIAMETER OF CONDUCTORS TO PREVENT OVERHEATING IN ELECTRIC CURRENTS.*

BY PROFESSOR GEORGE FORBES.

(CONCLUDED FROM PAGE 66.)

Having stated these preliminary facts, I shall now attempt an approximate solution of our problem.

PROBLEM III.—*A sheet of copper 1 centimetre thick and of a width b, buried at a depth d, carries a current C with a rise of temperature t above the surface of the ground, the ground being t'° above the surrounding air. When the steady flow of heat has set in, find the relation between these quantities.*

The heat generated per centimetre length per second

$$= \frac{C^2 R \times \cdot 24}{b};$$

The heat radiated† $= \cdot 0003 \times b \times t'$;

and these are equal.

$$\therefore C^2 = \frac{b^2 \, t'}{800 \, R}.$$

It would not be permissible to have the surface of the ground raised more than 5° C. in summer. Let us take 10° as a maximum value for t', $\therefore C^2 = \dfrac{b^2}{80 \, R}$.

We have also the equation of conductivity. (N.B.—Conductivity of paving stones and similar materials is ·004 to ·005, according to the experiments and deductions of Peclet, Herschel, and Lebour, J. D. Forbes, Thomson and Everett, Ayrton and Perry.) $\dfrac{C^2 R \times \cdot 24}{b}$ = heat conducted $= \dfrac{K \, b \, t}{d} = \cdot 004 \times \dfrac{b \, t}{d}$.

$$\therefore C^2 = \frac{\cdot 004 \times b^2 \, t}{\cdot 24 \, R \cdot d} = \frac{b^2}{80 \, R}$$

$$\therefore \frac{\cdot 004 \, t}{\cdot 24 \, d} = \frac{1}{80} \qquad t = \cdot 75 \times d.$$

With a depth of 2 feet, or 60 centimetres, the rise of temperature from the surface of the earth to the conductor is 45° C., and the difference of temperature between the conductor and surrounding air is 55° C. We might place the conductor under the foot pavement or street close to the surface. This would diminish the value of t, but practically we are not injured by taking a depth of 2 feet, as 50° C. is a permissible rise of temperature. Up to this depth, then, we need only consider the rate at which we can get rid of heat by cooling.

We have the equation $\quad C^2 = \dfrac{b^2}{80 \, R}$

and for 50° above the temperature of the air, assumed to be 15°, we have

$$R = 2 \cdot 031 \times 10^{-6} \text{ ohm},$$

$$\therefore C = \frac{b \times 10^3}{\sqrt{162 \cdot 48}} = 25 \, b.$$

The following table is calculated on these principles:—

Underground flat conductor of copper 1 cm. thick at a depth less than 2 feet below the surface, raising temperature of conductor less than 50° C.

Width of copper conductor 1 cm. thick.	Equivalent diameter of same section.	Current to raise surface temperature 10° C.
Cm.	Cm.	Amperes.
10	3·5	250
40	7·0	1,000
90	10·5	2,250
160	14·0	4,000
360	21·0	9,000
2,800	67·5	70,000

The second column is given to show the diameter of wire which would give the same quantity of metal, merely to admit of a comparison with the aerial conductors.

It appears, then, that if c = 70,000 ampères, we must have b = 2,800 centimetres, or the strip of copper must be 28 metres

* Paper read before Society of Telegraph Engineers and Electricians.

† It is assumed that the coefficient of cooling for the ground is the same as for a ball freely suspended. It is probably less.

Digitized by Google

wide. This gives the least weight of copper permissible (unless, indeed, we were to diminish still further the thickness), and it gives us a section = 53 centimetres square of pure copper, equivalent to a diameter of 67·5 centimetres.

I wish here to insist very positively upon the necessity of making such conductors for large currents in the form of flat sheets. Further, when we see the enormous mass of metal required, it is clearly necessary to use iron, which reduces the cost of material to about $\frac{1}{6}$. I hold this view very strongly in opposition to my friend Mr. Preece, who maintains that for electric light leads very pure copper should be used.

There is a very important application of the principles which have here been enunciated, and this is to the currents which can be carried by coils of wire when the wire is varied in thickness or the coil is varied in size. I have been sometimes simply astounded to see the waste of labour, time, and money which have been lavished on determining the proper thickness of wire with which to wind a coil without overheating for a dynamo field magnet, for regulating coils in arc lamps, &c., while the whole thing could be done by calculation. My first experiments to test the truth of the theory were undertaken two years ago. I first attacked the question as follows :—Having two coils of the same size, but rolled with wires of different diameters, so as to occupy the same volume and to have the same weight, then if the number of turns on each bobbin is considerable the length of wire is proportional to $\frac{1}{D^2}$ (D^2 being the diameter of the wire), and the cross-section is proportional to D^2, hence the resistance of each coil is proportional to $\frac{1}{D^4}$, and the heat developed in the circuit during a unit of time varies as C^2 R or $\frac{C^2}{D^4}$. But the radiating surface of the two coils is the same; whence, if the temperature be the same in both, the heat lost by radiation and convection in a given time is constant, and the heat created in unit time must be constant.

Whence $\frac{C^2}{D^4} = a^2$, where a is constant,

and $C = a\, D^2$;

i.e., to attain the same temperature with equal-sized bobbins, the current varies as the section of the wire.

To test the truth of this law I prepared two copper tubes, with flanges at each extremity, and closed at one end, and wound equal weights of two kinds of wire of different diameters. Filling one with water, and inserting a thermometer, the current was increased very slowly until a fixed temperature, sufficiently high, was steadily maintained. The tangent galvanometer was then read off. Afterwards the same temperature was attained with the other coil in the same way. The law above stated was exactly confirmed; the tangents of the angles were proportional to the squares of the diameters.

I next tested the theory in the case of the following problem: —*Two coils of similar shape have their linear dimensions in the ratio r : 1, and the thickness of wire in the same ratio; what ratio of currents is required to raise both to the same temperature?*

Let C R H be the current, resistance, and heat generated in the smaller coil, and C′ R′ H′ the corresponding quantities in the larger coil.

Then we have

$$C^2 R = a\, H, \text{ when } a \text{ is constant.}$$
$$C'^2 R' = a\, H'$$
$$R' = \frac{R}{n}.$$

Also, since the temperatures are equal, the heat radiated and convected in the two cases is in proportion to the surfaces, or as n^2 : 1, and this is equal to the heat generated, wherefore

$$H' = n^2 H,$$

or $$C'^2 R' = n^2\, C^2\, R,$$

or $$C'^2 \frac{R}{n} = n^2 C^2 R,$$

and $$C'^2 = n^3 C^2;$$

i.e., the squares of the currents are proportional to the cubes of the linear dimensions. To test this, Mr. R. Goodwin made for me the following experiments :—Coils of wire were wound upon two bobbins whose dimensions are—

Small coil—Length = 50 mm.;
Diameter of tube = 13 mm.;
Diameter of wire = 1·05 mm.;

Large coil—Length = 100 mm.;
Diameter of tube = 25·7 mm.;
Diameter of wire = 2·09 mm.

Here $n = 2$ and $n^{\frac{3}{2}} = 2{\cdot}83 = \frac{C'}{C}$ theoretically.

At the temperature of 63°C., the tangent galvanometer showed a deflection of 37° with the small coil, and at the same temperature with the large coil the deflection of 64°. The tangents of these angles are $0{\cdot}75355 \surd$ and $2{\cdot}0503 \surd$ respectively, the ratio of which is 2·72 : 1, which agrees well with the theoretical value.

It becomes an easy thing in any case to calculate the heating of a coil when we know its cooling surface and its resistance.

Let ρ = the resistance of a coil in ohms at the permissible temperature,
S = the surface exposed to the air measured in centimetres,
t = the rise in temperature,
C = the current in amperes.

$$\cdot 24\, C^2 \rho = \text{heat generated} = E\, t\, S,$$

where E is M'Farlane's constant varying from ·0002 to ·0003. The latter value may be taken. If 50° C. be the permissible rise in temperature

$$C = \sqrt{\frac{\cdot 0003 \times 50 \times S}{\cdot 24 \times \rho}} = \cdot 25 \sqrt{\frac{S}{\rho}}.$$

N.B.—It must be remembered in practice that the resistance (cold) must be increased by $\frac{1}{5}$ of its value to give ρ.

Example :—The resistance of the field-magnets of a dynamo is 1·5 ohm cold, and the surface exposed to the air is 1 metre: find the current to heat it not more than 50°C. Here S = 10,000, $\rho = 1{\cdot}8$ ohm, and $C = \cdot 25 \sqrt{\frac{10{,}000}{1{\cdot}8}} = 33{\cdot}5$ amperes. Those who are accustomed to handling dynamos will know that this is very much what we actually find, and it gives us confidence in the applications of theory.

Conclusion.

The general result of this research seems to be that we have the factors required for arriving at correct theoretical results. The general accordance of the theory with the few experimental facts which I have been able to get hold of, give a confidence in the application of these principles.

1. One of the most important results I have obtained is that the insulation of an aerial conductor is favourable, and gives us a power of using larger currents with conductors of the same size, when the diameters are not very great.

2. In small installations, the question of safety from fire or injury to insulation is not likely to crop up, but the tables here calculated will always be useful to let us know the amount of heating.

3. It is satisfactory to have a set of tables which will give us the increase of temperature with any arrangement of currents and size of wires. But these tables which I have worked out are not (except in the case of large currents) a measure of the best size of conductor for any special installation. They indicate only the safety from heating.

4. In buried conductors the mass of metal must be very great indeed, the inferior limit being set by the amount of heating of the surface of the ground which is permissible.

5. In all ordinary applications of coils of wire we can calculate the rise of temperature, experiment and theory being found to be in accordance.

TELEPHONE COMPANIES' GRIEVANCES.

If we are to imagine that the complaints preferred against the Postmaster-General by the Member for Carlow a fortnight ago faithfully represent the views of the telephone companies, there seems very little chance of those companies obtaining a remedy. Probably Mr. Gray treated the matter somewhat as a national grievance, and we all know to what dimensions that sort of grievance can be magnified when seen through the spectacles of an Irish patriot. It strikes us as unfortunate that the companies have been unable or unwilling to find a spokesman who would represent their case with moderation or fairness. But that is their affair; and although, as we have just remarked, their views, separately and independently, are not perhaps those with which they are credited by their exponent in Parliament, collectively they appear to be entertained more or less by many of the telephone companies; and all of them apparently give a sort of tacit countenance to the tactics of "trying it on," an art in which every Hibernian agitator is known to excel.

Setting aside Mr. Gray's violent language, and his unjustifiable charges brought against the officers of the Postal Telegraph Department as being wholly his own, what is it that the companies are striving to obtain? It is impossible to acquit them of trying it on to a considerable extent themselves for a long time past—indeed, from the very first. Their first attempt was on the whole a success. They were beaten in the Law Courts; but the head of the Post Office, unwilling to confiscate the property that had been created by the original experimenters, permitted them to go on enlarging it on terms which were certainly not very onerous. Having achieved this triumph, the companies forthwith endeavoured to set up a monopoly of their own to the exclusion of all competitors except those who joined in the game of trying it on at the outset. To have permitted this second attempt to go on unchecked would have resulted in the creation of a system which had all the faults of a State monopoly without any of its safeguards. The telephonic public would in fact have been at the mercy of one or two gigantic corporations, unless the Post Office itself had entered into competition with them, to have done which in real earnest would indeed have given just occasion for the complaint that the Post Office meant to "strangle" them. The Post Office, however, did not compete; it did the other thing—it granted licences to competing companies where good reason was shown for competition.

Profiting by the example of the parent companies, the new competitors have been trying to evade the obligation, imposed on the rest, to sell to the Postmaster-General as many of their instruments as he thought fit to purchase. To have given way on this point would have enabled any and all of the companies to avoid the obligation by asking for new licenses, and Mr. Fawcett did not give way. On the whole this experiment has not yet been more successful than the preceding one; but it has had the effect—it and Mr. Gray's eloquence—of inducing Mr. Fawcett to consider what can be done in the way of concession. It is stated that this condition imposed on the issue of fresh licences has checked the development of telephonic enterprise. If this is the case, it furnishes fresh proof that the enterprise thus checked has not been of a legitimate sort, but one which, in the general interests of the telephonic public, it is well to postpone for a while. The very essence of the monopoly, bought and paid for by the country and placed under the control of a State department, is that it shall be worked efficiently, and for this efficiency the State can have no guarantee if it grants licences for the work to be performed by outsiders without retaining any controlling influence over it. The right to compete is one which in the interests of the public it is the duty of the Postmaster-General to reserve to himself. His acceptance of a royalty on the traffic pledges him to see that it is done as well as the State would do it, and failing this, to step in and do it himself.

But, say the companies, the monopoly conferred by the Telegraph Act did not include the telephone. The Law Courts decided long ago that it did; and it is idle to raise the question again. Yet it is raised, if not directly, indirectly by the renewed complaints that the Government will not permit trunk lines to be used for experimental cheap telephony. A more direct encroachment on the functions of the telegraph could hardly be conceived, and it entirely cuts the ground from under the feet of those who used to maintain that a telephone system is not a telegraph system. This last "try on" has not succeeded, and probably never will, for the sufficient reasons, that, firstly, there is no good reason for believing that it would give satisfaction as an electrical experiment; and secondly if it would give satisfaction, the State department, which at present possesses the monopoly of the trunk lines, would work the traffic on its own account and under regulations both

Digitized by Google

financial and administrative that shall insure efficiency on the one hand and profit on the other. To do otherwise would be to transfer the business for which the nation paid ten or twelve millions sterling to the management and for the profit of private undertakings. And that this is what the companies have been trying to accomplish is shown by the exploits of Mr. Moseley at Manchester, who under the veil of "call offices" and "club subscriptions" has been virtually inviting the non-subscribing public indiscriminately to patronise the telephone instead of the telegraph. We do not object—nobody can object—to the telephone supplementing, or even superseding, the ordinary telegraph when it can do so satisfactorily. What we do object to is the transfer of the revenue derived from such operations into private pockets, when it rightly belongs to the public purse.

CORRESPONDENCE.

INFLUENCE OF STRESS ON THE ELECTRICAL RESISTANCE OF IRON AND STEEL WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was pleased to find from *The Electrician*, May 17, 1884, that Mr. W. H. Johnson, B.Sc., had been making some experiments on the alteration of the electrical resistance of steel and iron wires produced by excessive longitudinal traction. As Mr. Johnson had obtained for hard piano-steel results of a contrary nature to myself, who had in the case of steel only employed moderate stress, I arranged a pair of hard piano steel wires in the same way as the nickel wire used in my investigations on the "Influence of Stress and Strain on the Action of Physical Forces."* The mean diameter of the wire was ·08246 centimetre, and the total stress was carried up ot 100 kilogrammes, or nearly 2cwt. Part of this stress was permanent, and with the remainder the resistance of the wire was increased temporarily 2·68 per cent., the increase being proportional to the load, which was increased by equal amounts at a time. As the total stress was nearly sufficient to break the wire I was disappointed, inasmuch as I fully expected that the *specific* resistance of the wire would have first increased and then decreased. Instead of this I found with excessive stress, as I had some years ago found with moderate stress, that the resistance of a steel wire is increased by longitudinal traction about three and a half times as much as it is increased in length. On referring to the abstract of Mr. Johnson's paper it will be seen, however, that the value quoted by him for the elongation of the steel wire was an *impossible* one. The amount of stress used is not mentioned, but it is stated that by it a temporary elongation of *3 per cent.* was produced. Now the strongest pianoforte wire at present in use is that employed for deep-sea soundings, and it is capable of being elongated temporarily about *1·17 per cent.*, so that Mr. Johnson's wire would have to be nearly *three times* as strong as this.—Yours, &c.,

HERBERT TOMLINSON.

King's College, June 3, 1884.

TESTING LIGHTNING CONDUCTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On the 30th ult. I was called in to test two lightning conductors which had been quite recently repaired and put in *thorough* order by one of the well known erectors of lightning conductors in the north of England, and as these tests go far to show the need of testing I have pleasure in giving you the results:—

First conductor R of earth	440 ohms.
Second " "	1·25 "

Both conductors had been taken up and the earth connections made good during the last month.—Yours, &c.,

OHM.

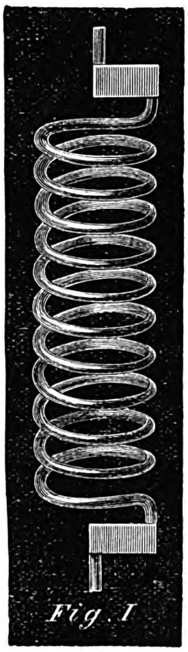
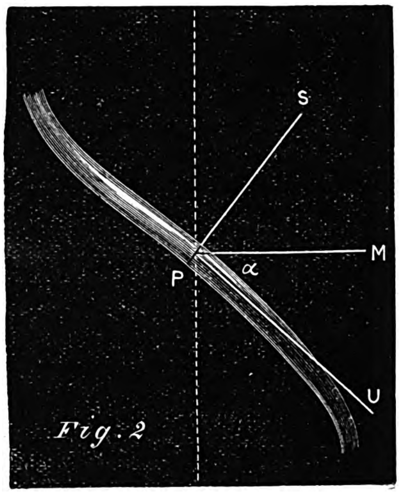
A NEW FORM OF SPRING FOR ELECTRIC AND OTHER MEASURING INSTRUMENTS.*

BY PROFESSORS W. E. AYRTON, F.R.S., AND JOHN PERRY, M.E.

In steam and gas engine indicators, the pressure of the fluid on a piston produces a slight shortening of a spiral spring which is magnified by a lever, and so the pressure of the steam or gas is recorded. In what are usually known as spring balances there is also occasionally a magnification of the elongation of a spiral spring effected by the use of a rack and pinion. Such magnifying arrangements, however, not only introduce inaccuracy by the bad fitting of hinges or of teeth, an inaccuracy which is aggravated by wear, but they increase the cost of measuring instruments and their liability to get out of order.

And, as an example of the difficulty of using a wheel and pinion for the magnifiation of an angular motion produced by a small force, we may mention that although we used this plan for a year or more in our electric measuring instruments, and although the wheels and pinions were made by a good watchmaker, still the friction involved in such a plan has induced us to abandon it in favour of the new arrangement which is the subject of this communication.





The telescopic method employed by Weber, and the spot of light method due to Sir W. Thomson for magnifying the effect of an angular motion are of course unequalled for stationary measuring instruments, but for instuments which must be carried about and used quickly without the necessity of adjustment these most ingenious reflecting methods are quite unsuitable.

With an ordinary cylindric spring, having a small angle between the osculating plane and a plane perpendicular to the axis, as is the case with all spiral springs such as are in practical use, and of which Fig. 1 is an example, it is well known that but very little rotation is produced between its ends by the application of an axial force. Consequently with such springs it is only possible to obtain magnification by the employment of a system of levers, or of a rack and pinion. It occurred to us, therefore, to consider whether it would not be possible to make a spiral spring of such a nature that for a comparatively small axial motion of its ends there should be considerable rotation of one end relatively to the other, and by the employment of which all levers, racks, and pinions could be dispensed with, so that no error could be introduced by wear and tear, or by want of fitting of joints, and further so that the temperature correction should be merely one affecting the rigidity of the material used as a spring, and not a correction such as has to be applied in consequence of the con-

tractions and expansions of the various parts of an ordinary magnifying apparatus.

In order to ascertain this fact, it is necessary to consider what are the general laws governing the behaviour of spiral springs. Let the centres of all cross sections of the wire or strip forming the spring lie on a right circular cylinder of radius r, let the spiral have everywhere an inclination a to the plane perpendicular to the axis of the cylinder, and let a force F act at one end of the spring along the axis, the other end of the spring being fixed.

In the cross section of the wire at any point P (Fig. 2) we have, due to the axial force F, tensile stress whose effect in deforming the spring may be neglected in comparison with the other effects to be described, and we have the stresses produced by a couple, Fr, acting about the axis PM. PS, PM, and PU are all in a plane tangential to the cylinder at the point P, PM being drawn in this plane perpendicular to the axis of the cylinder, PU tangential to the spiral line, and PS perpendicular to PU.

This couple is equivalent to the couple $\mathrm{F}r\cos a$, which is a twisting couple about the axis PU, and to $\mathrm{F}r\sin a$, a bending couple about the axis PS. If now B is the flexural rigidity of the wire in the osculating plane, and if A is the torsional rigidity about the spiral line at P we have

$$\frac{\mathrm{F}r\cos a}{\mathrm{A}}$$

as ~~the angular twist per unit of length~~ about the axis PU, and

$$\frac{\mathrm{F}r\sin a}{\mathrm{B}}$$

as the angular bending per unit of length about the axis PS.

Resolving both of these horizontally and vertically, we have for the total angular motion in a vertical plane, that is, about the axis PM,

$$\mathrm{F}r\left(\frac{\cos^2 a}{\mathrm{A}}+\frac{\sin^2 a}{\mathrm{B}}\right),$$

and for the angular motion in a horizontal plane

$$\mathrm{F}r\sin a\cos a\left(\frac{1}{\mathrm{A}}-\frac{1}{\mathrm{B}}\right).$$

If the angular motion, in a horizontal plane, of the free end of the spring relatively to the fixed end be called ϕ, and if the axial increase of length be called d, and the whole length of the spring along the spiral l, then

$$\phi=l\mathrm{F}r\sin a\cos a\left(\frac{1}{\mathrm{A}}-\frac{1}{\mathrm{B}}\right) \quad . \quad . \quad . \quad . \quad (1),$$

and

$$d=l\mathrm{F}r^2\left(\frac{\cos^2 a}{\mathrm{A}}+\frac{\sin^2 a}{\mathrm{B}}\right) \quad . \quad . \quad . \quad . \quad . \quad (2).$$

The theory of the strength and stiffness of the ordinary cylindric spiral spring for small angles was given, we believe for the first time, by Professor James Thomson, in the *Cambridge and Dublin Math. Jour.*, for 1848, and in "Thomson and Tait's Natural Philosophy," Vol. I., §§ 588-608, the general behaviour of wires subjected to forces at their ends is investigated, and we might have obtained equations (1) and (2) from the general result of that investigation given in Article 607, but we have preferred to deduce these two equations from first principles.

The general expression worked out by M. de St. Venant for A for a prism of rectangular section involves an infinite series, and its use would give rise to mathematical expressions of an unwieldy character in an investigation like the present. We have therefore decided to consider our strip of which the new spring is to be made as having an elliptic section. We may mention, however, for the benefit of students, that an examination of the expression given by Thomson and Tait, "Natural Philosophy," Vol. I., for the torsional rigidity of a prism of rectangular section has led us, we believe, to detect two errors in it; one is a misprint of nab^2 for nab^3, the other that the coefficient employed $\left(\frac{2}{\pi}\right)^5\frac{b}{a}$ ought to be $\left(\frac{2}{\pi}\right)^5\frac{2b}{a}$.

A friend of ours who has been kind enough, at our request, to check the investigation agrees with us in thinking that there are two errors, but considers that the second is not in the coefficient, but in the fact that $\frac{1}{3}$ has been used in the formula in place of $\frac{1}{6}$. We still are of opinion, however, that the error is in the coefficient, because when we employ our two corrections we obtain

$$\mathrm{A}=nab^3\left[\frac{1}{3}-\left(\frac{2}{\pi}\right)^5\frac{2b}{a}\Sigma\frac{1}{(2i+1)^5}\frac{1-\epsilon^{-(2i+1)\frac{\pi a}{b}}}{1+\epsilon^{-(2i+1)\frac{\pi a}{b}}}\right]$$

where a and b are the length and breadth of the strip, and this formula, we find, agrees with the experimental results of M. de St. Venant, and also with the calculated numbers given in Thomson and Tait's "Natural Philosophy," § 709, for the torsional rigidity of a square shaft; whereas neither the formula for A given in Thomson and Tait's book nor the formula as corrected by our friend will do this.*

Reverting to the elliptic section, if the principal semi-diameters of this ellipse are b, measured in the osculating plane of the spiral, and a measured perpendicular to this plane, the values of the two rigidities are—

$$\mathrm{A}=\frac{\mathrm{N}\pi a^3b^3}{a^2+b^2}, \text{ and } \mathrm{B}=\frac{\mathrm{E}\pi ab^3}{4},$$

where N is the modulus of rigidity of the material, and E is Young's modulus.

Hence substituting, equation (1) becomes—

$$\phi=l\mathrm{F}r\sin a\cos a\,\frac{1}{\pi ab^3}\left(\frac{a^2+b^2}{\mathrm{N}a^2}-\frac{4}{\mathrm{E}}\right) \quad . \quad . \quad (3).$$

$$d=\frac{l\mathrm{F}r^2}{\pi ab^3}\left(\frac{a^2+b^2}{\mathrm{N}a^2}\cos^2 a+\frac{4}{\mathrm{E}}\sin^2 a\right) \quad . \quad . \quad (4).$$

Maximum Rotation, Positive and Negative Springs.—If we merely require that ϕ shall be a maximum for a given axial force, F, independently of the stresses produced in the material, and independently of the axial elongation, then it is evident that a ought to be equal to 45°, and l and r as great as possible. If our other condition is that the area of cross section of the strip is to be a constant,

let $\qquad ab=s,$

and $\qquad a=kb,$

so that $\qquad b^2=\frac{s}{k}.$

Then

$$\frac{1}{\pi ab^3}\left(\frac{a^2+b^2}{\mathrm{N}a^2}-\frac{4}{\mathrm{E}}\right)=\frac{1}{\pi k\frac{s^2}{k^2}}\left(\frac{k^2+1}{\mathrm{N}k^2}-\frac{4}{\mathrm{E}}\right),$$

$$=\frac{1}{\pi s^2}\left(\frac{k}{\mathrm{N}}+\frac{1}{\mathrm{N}k}-\frac{k}{\mathrm{E}}\right),$$

or since N is equal usually to about two-fifths E, we find that

$$\phi\propto\frac{5}{k}-3k.$$

Now when k is very small this is very great. On the other hand, when k is very great this is also very great, but of the opposite sign. As k increases from 0 the expression to which ϕ, or the amount of turning, is proportional diminishes until when k reaches a value nearly 13, ϕ becomes 0, or there is no rotation of the spring produced by an axial force. In fact, for small values of k there is a rotation of the spring in the direction of the coiling, and the amount of rotation becomes the greater the smaller k is, while for values of k greater than 1·3 there is a rotation of the spring opposite to the direction of the coiling, the rotation becoming greater the larger k is.

Fig. 3 shows a spring in which k is greater than 1·3, and it is found that there is an uncoiling on the application of an axial force. Fig. 4 shows a spring made of the same material, but the wire has been passed through rolls so as to flatten it in the opposite way, and now a rotation tending to coil it up is found to be produced by the application of an axial force.

* Since this paper was presented Mr. R. T. Glazebrook has been kind enough to go through the investigation, and he confirms our correction of the formula as given in Thomson and Tait's "Natural Philosophy."

Digitized by Google

The twisting torque to which the spring is subjected is Fr cos α, and the bending torque to Fr sin α. But the twist must be multiplied by sin α, and the bend by cos α when we project these motions on a horizontal plane. So far, then, as the total rotation in a horizontal plane of the free end of the spring relatively to the fixed end is concerned, it may be regarded as being produced by equal twisting and bending torques, each of them equal to Fr sin α cos α; and the total rotation of the free end of the spring relatively to the fixed end, which is the special feature of the springs we are considering, is proportional to the difference between the two angular rotations produced in the wire by these equal bending and twisting torques. The twist alone would cause an increase in the number of coils, that is, a rotation in the direction of coiling, which is what we call positive, while the bending, or rather the unbending, alone would cause a negative rotation, or one tending to uncoil the spring. When both occur together in the actual spiral spring subjected to an axial force, the total rotation is positive or negative according as the angular twist or the angular bend is the greater. Hence the flexural and torsional rigidities of the wire alone determine whether the rotation is positive or negative.

It is well known, for example, that when a wire of circular section is subjected to equal twisting and bending torques the

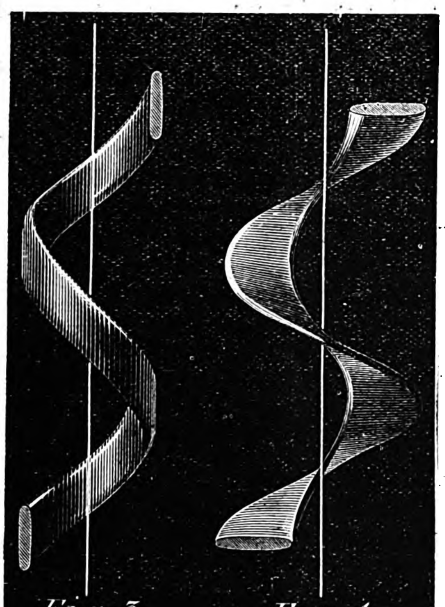

Fig. 5 *Fig. 4*

twist is greater than the bending for almost all substances, that is, substances in which the ratio of the modulus of rigidity to Young's modulus is between one-third and one-half. Hence we may expect that in a spring made of round wire, and with the spires making an angle of 45° with a plane perpendicular to the axis, the total rotation will be positive for an axial force applied so as to lengthen the spring. And experiment shows that this is the case.

If the wire be flattened and bent so that the flat side of the strip touches the cylinder on which the wire is coiled, as shown in Fig. 3, then the arrangement is such that the bending is greater than the twist. Hence an axial force applied so as to lengthen this spring causes a negative rotation, whereas if the strip be coiled as in Fig. 4, so that the edge of the strip lies against the cylinder on which it is coiled, an axial force similarly applied will now cause a positive rotation. It is almost certain that for any strip of material the positive value of ϕ obtained with the latter form of spring is likely to be greater than the corresponding negative value with the former kind, but the difficulty of manufacturing the second form of spring, where k has a very small value, has compelled us to confine our attention to the former type.

Permanent Set.—Having constructed some very delicate springs of this kind, one of the first difficulties which we met with arose from their liability to acquire a permanent set, so that it has been necessary to determine the dimensions of the spring which will give the largest amount of rotation with the minimum amount of stress in the material.

The shear stress at any point $x\,y$ in an elliptic section, if the prism has received a twist τ per unit length, is

$$N\left(\tau x + \frac{d\gamma}{dy}\right) \text{ in the direction of } y,$$

and

$$N\left(-\tau y + \frac{d\gamma}{dx}\right) \text{ in the direction of } x,$$

where

$$\gamma = -\tau\frac{a^2-b^2}{a^2+b^2}xy,$$

where a and b are the principal semi-diameters of the ellipse, the axis of y being parallel to the semi-diameter b.

Consequently these shear stresses equal

$$\frac{2b^2N\tau x}{a^2+b^2} \text{ and } -\frac{2N\tau y a^2}{a^2+b^2} \text{ respectively;}$$

and the total shear stress is equal to

$$\frac{2N\tau}{a^2+b^2}\sqrt{b^4x^2+a^4y^2}.$$

From this we see that the greatest shear stress is at the ends of the minor axis, and at the boundary is the least at the ends of the major axis.

If C is the twisting couple we know that

$$\tau = \frac{C}{A}, \text{ or}$$

$$\tau = \frac{C}{N}\frac{a^2+l^2}{\pi a^3b^3}.$$

Using these values of τ in the above we obtain for the total sheer stress at a point $x\,y$ of an elliptic section

$$\frac{2C}{\pi a^3b^3}\sqrt{b^4x^2+a^4y^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5),$$

and this at the extremity of the minor axis becomes

$$\frac{2C}{\pi a b^2}.$$

Applying (5) to our case where the twisting couple is Fr cos α, and the bending couple Fr sin α, and recollecting that the direction we have chosen for y on the section is perpendicular to the axis of the spiral, we see that at a point, $x\,y$, on the section bent about the axis of x—that is, x is perpendicular to the plane in which bending occurs—the shear stress q equals

$$\frac{2Fr\cos\alpha}{\pi a^3b^3}\sqrt{b^4x^2+a^4y^2} \quad . \quad . \quad . \quad . \quad . \quad (6),$$

and the tensile or compressive stress p at the point $x\,y$ due to bending equals

$$\frac{4y}{\pi a b^3}Fr\sin\alpha \quad . \quad . \quad . \quad . \quad . \quad . \quad (7).$$

And the resultant tensile, or compressive, stress f at the point $x\,y$ is

$$\frac{p}{2}+\sqrt{\frac{p^2}{4}+q^2},$$

therefore, since

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1$$

is the equation of the ellipse, the stress at the boundary,

$$f=\frac{2Fr}{\pi a b^3}\left(y\sin\alpha+\sqrt{y^2+\cos^2\alpha\frac{b^2}{a^2}(b^2-y^2)}\right) \quad . \quad . \quad . \quad (8).$$

We have now to consider for what value of y this expression is a maximum. The possible values of y are between 0 and b; and we see that if $1-\frac{b^2}{a^2}\cos^2\alpha$ is positive, f will be greatest when y has its greatest possible value, namely b. For sections 1, 2, 3, 4, therefore, of the strip shown in Fig. 5, where AB is the axis of the spring, the greatest stress will in each case be at B. If, however, b be very large compared with a, which is

Digitized by Google

the case in the section 5, Fig. 5, then f will not have its greatest value at B.

We find also that when

$$a < b \cos \alpha,$$

f has its greatest value when

$$y = \frac{ab^2 \sin \alpha}{\sqrt{(b^2 \cos^2 \alpha - a^2)(b^2 - a^2)}} \quad . \; . \; . \quad (9).$$

Now this value of y is greater that b so long as

$$a^2 b^2 \sin^2 \alpha > (b^2 \cos^2 \alpha - a^2)(b^2 - a^2);$$

and when these are equal we have

$$a^2 = b^2(1 \pm \sin \alpha)$$

where the positive sign is evidently inadmissible, since our condition above is a less than b.

Hence from b equal 0 through b equal a to b equal $\frac{a}{\sqrt{1 - \sin \alpha}}$, the greatest stress occurs at the extremity of the y axis. After that, the point of greatest stresss is nearer to a, but still on the circumference of the ellipse.

Now if b is very great compared with a, then we have as a limit

$$y = a \tan \alpha,$$

so that the greatest stress can never occur at the end of the semi-diameter a, but may be very near to it.

On the supposition then that, relatively to a, b has any value from 0 to $\frac{a}{\sqrt{1 - \sin \alpha}}$, the greatest stress in an elliptic section occurs at the end of the semi-diameter b, which is

amount of axial lengthening. As regards the value of α, it can easily be shown that $\frac{\phi}{d}$ will be a maximum when

$$\tan \alpha = \sqrt{\frac{E}{N} \cdot \frac{a^2 + b^2}{4a^2}}.$$

If b is small in comparison with a, which is a condition, as already explained, we are led by facility of construction to adopt, then

$$\tan \alpha = \tfrac{1}{2}\sqrt{\frac{E}{N}}.$$

As a rough approximation, taking N the modulus of rigidity at two-fifths of Young's modulus, the ratio given by M. St. Venant, this value of tan α becomes equal to $\sqrt{\cdot 625}$, or

$$\alpha = 38^\circ \; 19',$$

makes $\frac{\phi}{d}$ a maximum.

We have already seen, from (3), that to merely make ϕ a maximum for a given axial force, α ought to be 45°, and l and r as great as possible.

We are therefore led from three considerations—

1. That an axial force shall produce a maximum relative rotation;
2. That the rotation shall be great without producing permanent set in the material;
3. That the rotation shall be great in comparison with the elongation of the spring;

to make the angle of the spiral about 45°.

Further, to produce the first two of these conditions, it will be observed that the length of the wire forming the spring

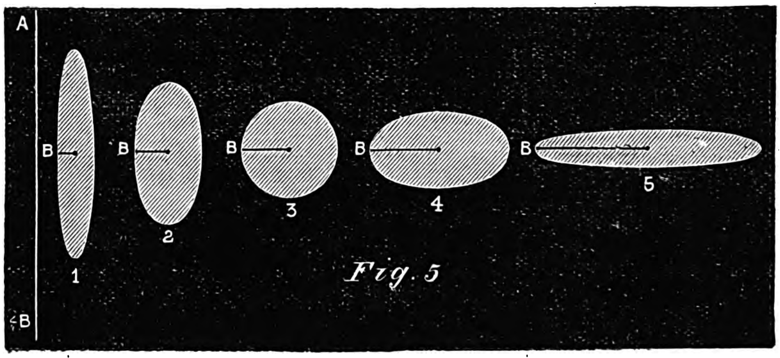

Fig. 5

parallel to the axis of y, and this is the case we will first confine ourselves to.

Maximum Rotation in Relation to Permanent Set.—If, now, f is the greatest stress at any point of the section,

$$\frac{\phi}{f} = \frac{1}{2} \frac{l}{b} \frac{\sin \alpha \cos \alpha}{1 + \sin \alpha} \left(\frac{a^2 + b^2}{Na^2} - \frac{4}{E} \right) \quad . \; . \; . \quad (10).$$

The conditions that make this a maximum are those which for a given axial force applied to our spring produce the greatest amount of turning of the free end with the least amount of stress on the material, and therefore with the least chance of permanent set. And as regards the value of α, it is clear that

$$\sin \alpha = -\tfrac{1}{2} \pm \tfrac{1}{2}\sqrt{5},$$

or

$$\alpha = 38^\circ \; 10',$$

will give the greatest value.

Maximum Rotation compared with Axial Motion.—From equations (3) and (4) we have

$$\frac{\phi}{d} = \frac{\tan \alpha}{r} \times \frac{\frac{a^2 + b^2}{Na^2} - \frac{4}{E}}{\frac{a^2 + b^2}{Na^2} + \frac{4}{E}\tan^2 \alpha} \quad . \; . \; . \quad (11),$$

and the conditions that make this a maximum are those which for a given axial force applied to the spring give the greatest amount of turning of the free end of it with the least

ought to be great, while the third condition is independent of the length.

Next, with regard to the proper radius r to give to the coils of the spring. ϕ increases with r, $\frac{\phi}{f}$ is independent of r, and $\frac{\phi}{d}$ varies inversely as r. Hence, as the first and third conditions are antagonistic one to the other, the value of r must be chosen to suit the conditions of the instrument in which the spring is to be used; that is, we must consider in any special case whether the possibility of permanent set or a large axial motion is more to be avoided in the particular instrument in question.

Let us now consider how ϕ, $\frac{\phi}{f}$, and $\frac{\phi}{d}$ depend on a and b. Referring to equation (3), if b is not greater than a, it is clear that the smaller b is the larger ϕ will be. Next putting N equal to $\frac{2}{5}$E, an approximation sufficiently accurate for the substances likely to be employed, we see from equation (10) that $\frac{\phi}{f}$ depends on

$$-\frac{1}{bE}\left(1 \cdot 5 - \frac{5b^2}{2a^2}\right),$$

and as in this first case we are limited to values of b between 0 and $\frac{a}{\sqrt{1 - \sin \alpha}}$, or between 0 and about 1·84 a if we put α equal to 45°, a value not far from that which we have already

Digitized by Google

determined to be the best, then it is obvious that the smaller b is the larger will be $\frac{\phi}{f}$.

From equation (11) we see that $\frac{\phi}{d}$ depends on

$$\frac{(a^2+b^2)\,E - 4Na^2}{(a^2+b^2)\,E + 4Na^2};$$

or, putting N equal to $\frac{2}{5}$ E, this becomes

$$\frac{5\frac{b^2}{a^2} - 3}{5\frac{b^2}{a^2} + 13}.$$

Hence, remembering as before that b^2 has only values between 0 and $3{\cdot}4a^2$, we see that the last fraction varies between $-0{\cdot}23$ and $+0{\cdot}47$.

Hence, taking b small, which gives the greatest values for ϕ, and $\frac{\phi}{f}$, gives a value for $\frac{\phi}{d}$ not less than half as great as if we had taken the largest possible value of b.

Finally, therefore, if b varies from 0 to $\frac{a}{\sqrt{1-\sin\alpha}}$, the best practical value of b is an extremely small one, or the strip should be wound as in Fig. 3.

If b is greater than $\frac{a}{\sqrt{1-\sin\alpha}}$, conditions other than those given above may make $\frac{\phi}{f}$ and $\frac{\phi}{d}$ have their maximum values; but, since the difficulty of manufacturing metal springs of the form shown in Fig. 4 must necessarily render their employment but very limited, a mathematical examination of this problem has not much practical value. We therefore merely mention that in this case calculation shows that

$$\frac{\phi}{f} = \tfrac{1}{2} la \tan\alpha \left(\frac{a^2+b^2}{Na^2} - \frac{4}{E}\right)\frac{1}{b^2}\sqrt{\frac{b^2\cos^2\alpha - a^2}{b^2 - a^2}} \quad . \quad (12),$$

where f is the maximum stress anywhere in the section, the maximum stress in this case not occurring at the extremity of the b diameter.

The general conclusions therefore arrived at are, that in order with a given axial force to obtain a large amount of turning of the free end of the spring, combined with small maximum total stress in the material, and not too much axial motion of the free end of the spring, the strip of elliptic section should be as long and as thin as possible, should be wound in a spiral such that the osculating plane makes an angle of 40° to 45° with a plane perpendicular to the axis of the spiral, and so that the smaller diameter of the elliptic section is at right angles to the axis of the spiral.

Under these circumstances, $2a$ being the major diameter and $2b$ the minor diameter of the ellipse,

$$\phi = \frac{2lFr\sin 2\alpha}{\pi ab^3}\left(\frac{1}{4N} - \frac{1}{E}\right) \quad . \quad . \quad . \quad (13),$$

f the maximum stress at a section

$$= \frac{2Fr}{\pi ab^2}(1+\sin\alpha) \quad . \quad . \quad . \quad . \quad . \quad (14),$$

and

$$d = \frac{lFr^2}{\pi ab^3}\left(\frac{\cos^2\alpha}{N} + \frac{4\sin^2\alpha}{E}\right) \quad . \quad . \quad . \quad (15).$$

(TO BE CONTINUED.)

ERRATA.—In the article on "Tubular Carbons," published in our last issue, there are some slight errors which require correction. In the formula for the resistance of a cylindrical filament (p. 61), for

$$R = \frac{4}{\pi\delta^2} + l + a \text{ read } R = \frac{4}{\pi\delta^2} \times l \times a.$$

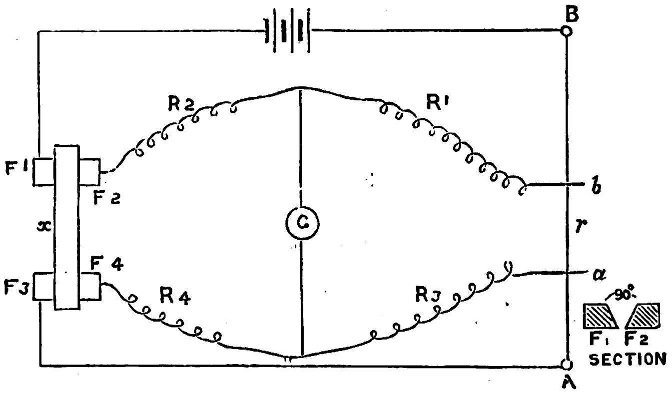
Line 16, p. 62, M. Bandsept writes, in reference to the translator's note of interrogation after the word "electrolytic action," that his meaning is perhaps better expressed by "electrolytic process," since he was speaking of a dislocating effect due to a shaking motion (ébranlement), which is more violent at the point where the current enters the carbon.

FORM OF BRIDGE FOR THE MEASUREMENT OF VERY SMALL RESISTANCES.

BY E. C. RIMINGTON.

There appeared in the *Journal* of the Society of Telegraph Engineers and of Electricians, Vol. XII., page 620, an abstract from *L'Electricien*, describing a form of bridge for the measurement of very small resistances, such as those of brass bars, carbon rods, &c.

The rod to be measured is laid upon four brass blocks $F_1F_2F_3$ and F_4, shown in section. F_1 is connected to the battery, F_2 to



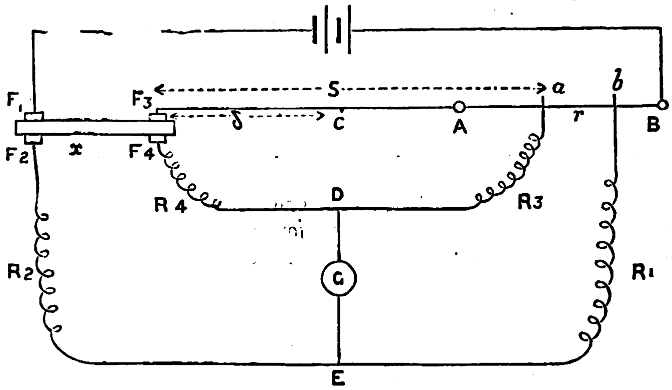
the resistance R_2, F_4 to the resistance R_4, and F_3 to A, one end of a stretched wire of German silver AB, the other end B being connected to the battery. Two contacts, a and b, attached to the resistances R_3 and R_1, slide on this wire. The resistances R_1 R_2 R_3 and R_4 remain constant, while the sliding contacts a and b are moved until there is no deflection on the galvanometer G. When this happens, according to the article, x, or the resistance of the bar between the blocks,

$$= \text{the resistance between } a \text{ and } b \times \frac{R_2}{R_1}$$
$$= \text{,, ,, ,, ,,} \times \frac{R_4}{R_3}$$

and moreover it states that the resistance measured is independent of the good or bad contact of the bar with the brass blocks.

This is decidedly incorrect, as the resistance does depend on the contact that the bar makes with the brass blocks, as I will proceed to prove.

The following diagram will perhaps show the arrangement better:—



Call the resistance of the bar x.

" " between the contacts a and b, r.

" " " a and F_3 S.

Now, when there is no current through the galvanometer there must be some point C in S such that, if we call the resistance between C and F_3 δ, $\frac{\delta}{R_4} = \frac{S-\delta}{R_3}$,

and

$$\delta = \frac{R_4 S}{R_3 + R_4};$$

Digitized by Google

consequently the resistance betweeen C and a or $S - \delta$

$$= \frac{R_3 S}{R_3 + R_4}.$$

The points C, D, and E are all at the same potential; we can therefore suppose the points C and D joined by a thick wire of no resistance. We then have

$$\frac{R_1}{R_2} = \frac{r + \dfrac{R_3 \dfrac{R_3 S}{R_3 + R_4}}{R_3 + \dfrac{R_3 S}{R_3 + R_4}}}{x + \dfrac{R_4 \dfrac{R_4 S}{R_3 + R_4}}{R_4 + \dfrac{R_4 S}{R_3 + R_4}}}$$

$$= \frac{r + \dfrac{R_3 S}{R_3 + R_4 + S}}{x + \dfrac{R_4 S}{R_3 + R_4 + S}}$$

$$\therefore \; R_1\left(x + \frac{R_4 S}{R_3 + R_4 + S}\right) = R_2\left(r + \frac{R_3 S}{R_3 + R_4 + S}\right),$$

or $$R_1 x - R_2 r = (R_2 R_3 - R_1 R_4) \cdot \frac{S}{R_3 + R_4 + S}.$$

To eliminate the unknown resistance S we must make the coefficient of $\frac{S}{R_3 + R_4 + S}$ = zero.

$$\therefore \; R_2 R_3 = R_1 R_4$$

or $$\frac{R_1}{R_2} = \frac{R_3}{R_4} \quad \ldots\ldots \quad (A)$$

If this be so, we have

$$R_1 x - R_2 r = 0,$$

$$\frac{x}{r} = \frac{R_2}{R_1};$$

$$\therefore \; x = r \cdot \frac{R_2}{R_1}.$$

We must now see what effect the resistances of the contacts F_1 F_2 F_3 and F_4 have on the accuracy of the determination of x.

The resistance of F_1 evidently does not effect the result, as it simply adds to the resistance of the wire from the battery, so it is perfectly immaterial what resistance the contact F_1 is.

The resistance of F_3 also only adds to the resistance S, which we eliminated by making

$$\frac{R_1}{R_2} = \frac{R_3}{R_4}.$$

But the resistances of the contacts F_2 and F_4 add to the resistances of R_3 and R_4.

Suppose all the resistances R_1 R_2 R_3 and R_4 are equal, *e.g.*, = R, and the resistance of $F_2 = \rho$, and of $F_4 = \rho_1$, then instead of (A) we have

$$\frac{R}{R + \rho} = \frac{R}{R + \rho_1}.$$

For this equation, then, to hold good ρ must equal ρ_1; if this be so we obtain

$$x = r \cdot \frac{R + \rho}{R}.$$

This brings in the resistance of ρ, which is indeterminate, and we cannot therefore find the true value of x.

If the resistances R_1 R_2 R_3 and R_4 are considerable, say 10 ohms or more each, and the contacts F_2 and F_4 are kept clean so that their resistances are very small compared with R_1 R_2, &c., we have

$$x = r \frac{R_2}{R_1} = r \frac{R_4}{R_3} \quad \text{approximately.}$$

THE LALANDE-CHAPERON BATTERY.

BY F. DE LALANDE AND G. CHAPERON.

To obtain a practical battery out of the various models of the oxide of copper cell, whose principle we made known in 1881, it was necessary to make an extended series of experiments,* the result of which may be of interest. Our object was to form a double voltaic element which would be constant for a long period. The conditions to be fulfilled in order that a couple may accomplish this are very difficult to attain; in the first place, the products should only be used when the circuit is closed, so that all combinations of two liquids are interdicted. It is requisite, therefore, to find a combination in which there is a depolarising solid. The metal to be attacked also should not react on the liquid in which it is immersed when the battery is not at work. Passing in review the series of metals, and the electrolytes which will attack them whose price permits of their use, we found that the limit of combinations in this case is very narrow. This limit is still further narrowed if we require a large amount of work from the chemical action between the metal and liquid with a closed circuit. Thus there remains little more than zinc in ammoniacal salts, or very well amalgamated zinc in acids which seem likely to accomplish the end in view. But ammoniacal salts will dissolve but a very small quantity of zinc before they give rise to insoluble crystals, which shield the metal from attack; and as regards amalgamated zinc it is very readily dissolved in dilute acids, the result being a loss which is prohibitive for a constant battery. Another combination answers far better to the conditions imposed. This is zinc and a concentrated alkaline solution. Described at different times in special treatises it had been brought to the notice of specialists at the time when we began our experiments by various articles, and amongst others those describing the Reynier battery. Potash or caustic soda mixed with water in the proportion of about 30 to 35 per cent., for instance, possesses the remarkable property of not attacking zinc in an open circuit (nor, indeed, tin, lead, and other metals), has a very small electrical resistance, and, finally, has the power, when the battery is at work, of dissolving as rapidly as acids considerable quantities of metal without giving rise to any crystallisation or deleterious deposit. It was to be hoped, therefore, that by combining zinc and an alkaline solution with an efficient depolarising solid, we could fulfil the necessary conditions for a cell which should remain mounted for a long period, like the Leclanché, whilst furnishing a constant and large current, several amperes for instance, though but of small dimensions.

Following out this train of thought, the trial of metallic oxides as depolarising material, a large number of which are insoluble in alkalies, was naturally indicated. Among all those examined by us, none seemed to supply electrodes of such capacity as oxide of copper. Peroxide of manganese, one of the first used by us, gives a high E.M.F. with an open circuit, but in alkali elements, as also in sal-ammoniac elements, polarisation ensues very quickly for a duty of some importance. We did not think it worth while to follow up the examination of this combination subsequently discovered and extolled by M. Leuchs. The various oxides of iron, natural or artificial, turned out badly, and were not reduced in any appreciable manner in the battery. However, the small layer of oxide formed by oxidation through heat on plates of iron placed at the positive pole was reduced rapidly enough, and made good contact with depolarisers, even solids. This quality of making with the positive electrode sufficiently good contact to allow the battery to work well, to make good contact, is very variable, not only with the nature of the oxides, but also with their physical state. Thus oxide of copper formed by roasting copper in the air is generally found to be in good condition for use, whilst the oxide which is chemically precipitated makes far inferior contact with the electrode. The bioxide of mercury, which it would appear should show properties very much resembling those of oxide of copper, depolarises slowly and badly, whether it is used with a support of copper,

* The authors acknowledge the services rendered to them by Dr. A. D'Arsonval in carrying out these experiments.

Digitized by Google

iron, carbon, or even mercury. Oxides of the precious metals (silver, platinum, gold) give high electromotive forces and depolarise regularly. Oxide of silver has given, in M. D'Arsonval's hands, an E.M.F. of more than 1½ volt. Unhappily the price and the high molecular weight of silver render its use very limited. The battery thus formed is not completely reversible; the silver reduced to oxide in the working of the battery only absorbs electrolytic oxygen in an incomplete manner, whilst with copper the absorption is complete up to perfect oxidation. The same electromotive forces are obtained in fact by the use of the oxide or chloride; the latter, having a heat of formation far higher than that of the oxide, evidently will not give the same E.M.F. unless it undergoes a preliminary transformation. High electromotive forces might be hoped for with the higher oxides of nickel and cobalt obtained by an electrical recharging of elements working as secondary batteries, but these products make bad contact with the supports. Oxide of bismuth, on the contrary, which is formed by using the lower nitrate, might answer readily, but it is very inferior to oxide of copper. Bioxide of lead cannot be used.

Having ascertained in a general manner that the combination of the properties of oxide of copper and those of alkaline solutions enabled us to construct a cell which would last and give a high duty, it remained for us to design simple forms for different uses. The use of agglomerate depolarising solids in these days has been much upheld, and we tried at first to obtain oxide of copper in this form. We have obtained products having energetic depolarising properties, and offering great resistance to the dissolving action of caustic alkalies. They are prepared by mixing a small quantity of oxychloride of magnesium with oxide of copper, and moulding the material on a metal support to ensure contact. This method of using the oxide readily permits of the formation of elements of small volume and large surface. It is necessary to remark, however, that under ordinary conditions, when the battery must not be recharged after running down, these agglomerate plates become, as in the Leclanché cell, a useless residue, and the work expended in their manufacture is entirely thrown away. On the other hand, the pure metallic copper obtained by the reduction of the unmixed oxide is far from being valueless. Accordingly it seemed to us more practical to apply the oxide to the conducting support, which in this case should be horizontal by its own weight alone. We have already described different models constructed under these conditions in which the depolarising material rests on a plate, or better still, at the bottom of a metal jar. This is, in point of fact, the most handy form for numerous purposes. The use of agglomerate plates should be reserved for special cases.

In these cells the zinc is placed in the upper part, and when in work the very dense solution of zincate of potash which is formed falls to the bottom of the jar, where it lies in a syrupy layer, so that to the very end the zinc is in contact with the dilute alkaline liquid which should attack it. This it does under these conditions with perfect regularity, whilst plates of zinc immersed as far as the bottom of batteries of the same kind are eaten away with increasing rapidity from bottom to top. A plate of zinc 3 millimetres thick, placed horizontally, can be eaten away so regularly as to have at last a uniform thickness of only two to three tenths of a millimetre. In batteries at rest the separation of the solution of potash and the saturated solution of zincate which falls to the bottom may be clear enough to permit of renewing the exciting liquid by siphoning off the saturated parts to replace them. Soda gives apparently the same results as potash, both as regards E.M.F. and internal resistance. We usually employ potash, as we have already pointed out, to avoid the formation of creeping salts. This inconvenience can, however, be avoided in large cells by simply covering the surface with a liquid not attackable by soda. It is useful to employ sufficiently concentrated solutions, up to 30 or 40 per cent. for instance. In point of fact a solution containing five or six per cent. of potash dissolves but very little oxide of zinc; and a solution of alkaline zincate precipitates oxide of zinc when diluted with water. There is therefore a far greater relative proportion of unused alkali the more dilute the solution is. When the alkaline solution in the battery is saturated, though the circuit be closed, the zinc continues nevertheless to be attacked; but then oxide of zinc is deposited as much at the bottom of the jar as on the zinc, which it covers with a hard crust. The appearance of these deposits indicates the exhaustion of the battery. The carbonic acid of the air is absorbed by the potash of the batteries, especially if the surface is not protected by a cover or layer of liquid. This absorption, which otherwise is very slow, is only inconvenient so far as it renders useless the quantity of potash converted into the carbonate state. When the alkaline solution is saturated with oxide of zinc and remains exposed long enough to the action of the air, it causes insoluble crystals to be deposited in water which appear to be oxide or hydrate of zinc. One serious inconvenience is found in nearly all batteries intended to remain untouched for a long period; this is that the zinc, even with an open circuit, is rapidly attacked at the level of the liquid and to a small distance below the surface. It may in this way be completely cut in two, even if it be a thick plate, and the working of the cell be stopped. The use of insulating varnish or protecting bands of india rubber gets over this difficulty. If the zinc be suspended by a wire or rod of any other soluble metal, a local couple is formed which rapidly destroys the electrode at the point of attachment. In common with M. D'Arsonval we thought of using a rod or plate of brass or of amalgamated copper as a support for the zinc. Amalgamated zinc will not form a couple with amalgamated brass, even after a long period of immersion. This method we have adopted for all batteries required for any length of time. The zinc is always completely immersed and suspended by a conductor of amalgamated brass connected with a terminal.

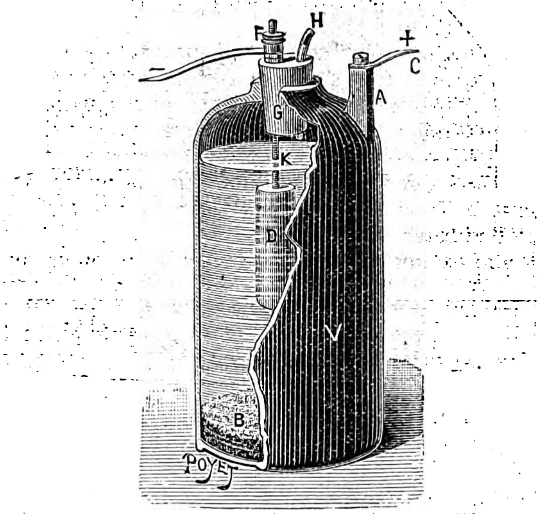


Fig. 1.—Lalande and Chaperon's Small Cell.

The oxide of copper battery can be made in many different forms, according to the service it is intended for. Besides the models already described we have designed others with an external iron jar, which offers the advantage of being hermetically closed, readily portable, and of great solidity—very important qualities for cells enclosing a caustic liquid. In one of these forms (Fig. 1) the outer jar, of ·09m. diameter, looks like a shell. It constitutes the positive pole; a terminal, A, projects as shown. The outside of the jar is paraffined when cold, so as to prevent rust and short circuiting. The zinc D is formed of a cylinder ·02m. in diameter, soldered to a rod of amalgamated brass, K, fitted in an india rubber tube, G, and carries the terminal F. The tube is also traversed by a metal tube terminated by a plug, H, formed of split india rubber tubing. These cells are usually delivered filled with the potash solution, so that to mount them it is only necessary to throw in the proper quantity of oxide of copper, which spreads over the bottom at B, and to close the cell by means of the india rubber stopper carrying the zinc. This arrangement is particularly handy for use in rooms for telephones or electric bells. This type will give a duty amounting to nearly two

Digitized by Google

amperes. A smaller type of ·05m. diameter is fully capable of several years' electric bell work.

Fig. 2 shows another type of hermetically closed cell which has more recently been brought into use. It has a large surface, ·22m. diameter, and gives a duty of 8 to 10 amperes, which allows of its being used for the same purposes as the Bunsen and bichromate batteries, viz.:—Charging accumulators, lighting houses, electro-plating, induction coils, &c. The arrangement of this cell is very similar to that of the foregoing. The oxide of copper B is similarly spread over the bottom of the jar; the zinc D, consisting of a long plate rolled in spiral form to offer a large surface, is suspended from an ebonite cover, G, fitted on to the mouth of the jar by means of screws, as shown, and having an india rubber washer to secure the joint. These large elements have the same charge as our large trough cells, viz., two kilograms of potash and ·900 kilogram of oxide of copper, and can be used instead of them for all purposes. They are capable of a considerable amount of work. For instance, a trough battery has kept an Edison 5-candle lamp alight for more than 200 hours. By using six elements we have been able to carry on nickel-plating work during nearly two months at the rate of seven hours per day, which required three Bunsen elements. The latter required to be remounted every two days, and did not give nearly such a constant current, thus causing numerous troubles. These iron batteries have the remarkable property of being able to give without polarisation a duty far higher than corresponding

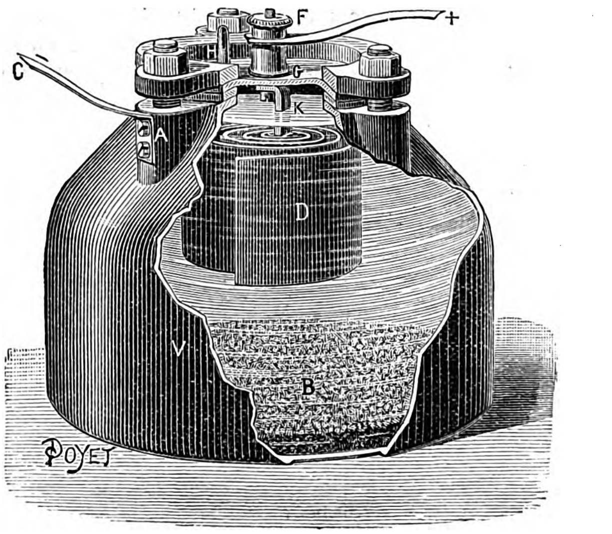

FIG. 2.—Lalande and Chaperon's Large Cell.

non-metallic cells, whose conducting surface in contact with oxide of copper should be as large. As no hydrogen is disengaged at the iron, it seems to us that its large surface must nevertheless be charged with occluded hydrogen, which is carried gradually as far as the oxide of copper, and thus assists the depolarising action in a continuous manner.

It remains for us to design some practical reversible batteries, having a large and small duty. When an oxide of copper battery is exhausted, and a suitable current is made to traverse it, the oxygen at the positive pole is wholly absorbed by the reduced copper; but if the support of the depolarising material is of copper, a small quantity of the latter is dissolved, giving a blue colour to the liquid. The copper obtained by the reduction of the oxide, however, is not dissolved. We have ascertained that by employing iron or cast iron as a support, this attacking and dissolution of the copper is avoided, provided that the oxide used has been free at the outset from metallic copper. The great difficulty lies in the deposit of zinc. This metal is precipitated in a form which is not sufficiently coherent, particularly when it is required to have moderate thicknesses. We avoid this difficulty either by precipitating the zinc on a very large surface of brass or amalgamated copper, on a mass of copper shavings for instance, or by precipitating it on a horizontal surface of amalgamated brass, covered with an excess of mercury and furnished with depressions for this metal to lodge in. The under part of this support is further covered with an insulator. The zinc can then only arrange itself on the surface, and as it immediately amalgamates the deposit becomes coherent, and can without loss furnish a fresh amount of current by its dissolution. We hope shortly to describe reversible batteries constructed in accordance with the foregoing data.

LITERATURE.

Electricity: Its Theory, Sources, and Application. By JOHN T. SPRAGUE, M.S.T.E. and E. Second edition. [E. and F. N. Spon.]

Those who know something of books will bear out the statement that originality in bookmaking is somewhat rare. The majority of books published—and especially is this the case with scientific books—follow pretty closely the lines of preceding books. Among the few original works on electrical subjects this of Mr. Sprague takes a very high position. There is hardly a page throughout his book of 650 pages which does not indicate originality of thought. A, B, or C may say this or that, but the author writes as one who, dissatisfied with blindly following mere authority, has tried the experiment for himself, and gives us the conclusions obtained under these conditions. Mr. Sprague never hesitates to say where he thinks authorities are wrong, or rather to give his reasons for thus thinking, allowing his readers to judge of the correctness of his conclusions. The present writer had the pleasure of reviewing Mr. Sprague's work in its first edition, and is gratified to see that some of the suggestions then thrown out have borne fruit. The present edition is greatly enlarged and has practically been rewritten. We can do no more than indicate its contents, making here and there comments, for to review it carefully would necessitate the writing of chapters as lengthy as some in the work itself.

In his first paragraph Mr. Sprague tells the student the directions in which his studies should tend if he hopes to learn much about electricity. He says:—"Before we can understand electricity and its various applications we require to have some knowledge of the fundamental principles of mechanics, the laws of motion, energy, force and heat; and, above all, we need some considerable acquaintance with the general principles of chemistry." We do not think Mr. Sprague is quite fair to the mathematicians. We doubt if the mathematicians have ever claimed to be the true and only exponents of the science. They rather maintain the position that being given the results of experiment they have reduced these results to mathematical analysis, and have presented the subject more in the nature of an exact science than is possible in the hands of the pure physicist. To forward the knowledge of the subject we lean towards the experimentalist, of whom Faraday stands pre-eminent. To forward the practical application we lean towards the mathematician, who, by means of his formulæ, places a weapon of attack in the hands of thousands who would not otherwise be able to contribute to progress. We contend that the pure physicist and the mathematician are coequal, the superior of either being a combination of the two. Can we give a better example of the latter than Sir W. Thomson?

Towards the end of the introductory chapter which treats of atomicity, molecular types, force, energy, &c., Mr. Sprague gives the text upon which his book sermonises:—

"According to the theory adopted in these pages, electricity is not material or a quasi-material fluid, nor is it a special force; it is a form of motion—energy charged in a special manner upon ordinary matter, and developing special relation among its molecules. Since the first edition of this work was published this view has gained much ground, and many things which were then regarded as heresies are now generally adopted as true scientific principles.

"But while scientific men are fast coming to this view of electricity, and it is very commonly employed, more particularly with dynamic electricity or galvanism, still the new theory is rarely fully set forth and substituted for the old fluid theories, and therefore it is very difficult for students to

Digitized by Google

obtain that clear view of the subject which is desirable, especially as all the older terms of the science were devised in connection with the old theories, and are exceedingly ill-fitted to convey the new one without producing much confusion of ideas.

"This work in its original form was intended to meet this requirement, and the plan adopted has been to commence with a few leading facts and principles, then describe the various forms of instruments necessary to examine the actions of the force, and by their aid trace out the general laws and fundamental principles of the science, after which the applications of the force of which the nature has been thus examined will become far more intelligible than by piling up isolated facts, or describing mere processes however practically valuable."

In the next edition we would suggest that all reference to "Static Electricity" be omitted, except perhaps to say the "definition" is obsolete, and that all the phenomena hitherto discussed under this head can be better discussed under a subhead of dynamic electricity. The author, p. 16, now says "static electricity is, however, a misnomer, it has no existence," and he may therefore well go the other step and ignore it altogether. We are glad to find that in this edition "electrical repulsion" *is* thrown overboard. After referring to the ordinary statement in books, and, in a note, to the comment of a reviewer on the first edition, the author says, p. 22: "Hence it is stated, as a fundamental law, that bodies similarly electrified repel each other, *which is not true*, so stated;" and again, p. 57: "*Repulsion* is an indirect action of attraction. Nowhere in nature can there be found a repulsive force." We claim the credit of being first to distinctly state this heresy. Although Mr. Sprague held it when writing his first edition, he did not speak decisively on the matter. Now, however, we have it, and while an anonymous scribe like the writer may be allowed to formulate heresies and heterodoxies without attracting the slightest attention, the mere fact than an author of repute has accepted them will cause them to be closely examined and criticised. Most unhesitatingly we throw in our lot with the author. When the critics hit him we shall take shelter behind his shield. When he hits the critics we can bask in the sunshine without danger of hurt. Let us make certain, however, of how we stand. We do not agree with *all* Mr. Sprague says in this book; in fact, we do not quite grasp his idea of "energy charged in a special manner upon the molecule." We only at this point state our entire agreement with him as regards the non-existence of electrical repulsion.

The theory adopted by Mr. Sprague to explain the phenomena of the science is the "molecular theory." The molecule must be considered "as a body composed of two distinct parts linked together, but acting also as a whole from a common centre," p. 25. The two halves of the compound molecule vibrate around a central line, and a force intensifying the vibrations has the effect of breaking up the molecule giving the phenomenon of discharge. The idea of polarised molecules is explained, and the law given that "Electrical action is developed only when a complete chain of polarised molecules can be formed," p. 26. Has Mr. Sprague ever pursued the idea that the real law is just the opposite of this, which may be stated that "Electrical action is developed only when a completed chain of polarised molecules is distorted or broken?" There is another question, too, in this part of the subject which might well receive consideration. Assuming the correctness of the molecular theory, work is done in forming the chain of polarised molecules. On p. 34 we read:—"Generally it may be said that any molecule when polarised *induces* all others within its influence to follow its example, that is to say, employing the true meaning of the word, it *draws them* into the same systematic order. . . ." The molecules we presume are similar in all respects, vibrating in a sea of ether. In what way can we conceive one polarised molecule to draw or act upon a number and expend or, rather, transmit work; for it is through some action of this polarised molecule that the force necessary to polarise the chain is transmitted. At present our only conception of the action is that the ultimate molecule is not perfectly spherical, that it is restrained by the acting force in a given position, and that therefore its mean path in a given direction is altered with its axis in a given direction, and that owing to the elasticity of the ether the paths of the surrounding molecules is altered till the axes of all the molecules vibrate in parallel planes. Will Mr. Sprague help us to try and picture in our mind's eye the polarising action which he thinks goes on? It is far easier to talk about molecules being polarised than to explain how they are polarised.

One or two paragraphs at the end of the chapter on magnetism are so important for the student to grasp that we are fain to quote them:—On p. 114 our author says, "Before leaving the subject of magnetism it will be well to point out the error of the common conception of magnets as inexhaustible sources of force. It is this misconception which has led so many to waste their time in trying to devise perpetual motion machines, of which magnetism was to supply the motive power. It has also given rise to many questions as to how it is that a magnet can impart force to any number of other magnets without itself parting with any force.

"Magnets, like springs, can only exert the power which has been put into them—*they have no force of their own.* In the act of magnetising, whether by magnets or by electricity, a certain amount of energy is charged upon the molecules, just as it would if each of the molecules in Fig. 33, p. 94, were a spring, which was wound up in the act of magnetising. When the magnet exerts any force, *it parts with that force;* it is to that extent exhausted, and the energy it parts with is distributed over the new 'field,' or in the armature, &c., which has been moved. If the armature is a mass of iron as large and heavy as the magnet can hold, the magnet is exhausted, it will no longer affect external magnets, &c., or but very slightly. Before the magnet can exert any further force the requisite energy must be restored to its molecules. This is done by removing the armature, which requires an exertion of force equal to that exerted by the magnet in attracting it."

We must, however, pass on more rapidly, or we shall give no conception of what is in this work. But really Mr. Sprague is to blame for our verbosity. He says so much to make us think that we are induced at every paragraph to fly off at a tangent to the object immediately in hand. The author describes very clearly the importance of the inductive circuit, the theory of the ordinary frictional machines, the nonsense that is so often written and said about the earth connection, specially describing and illustrating, p. 41 and p. 618, the Voss and the Wimshurst induction machines, and other inductive apparatus. The whole of this (the early part of the book) should be most attentively read by the student. It contains information wholly undiscoverable, because wholly unknown to the writers, in the majority of text-books. Chapter III. treats of magnetism, and is an extension of Mr. Sprague's articles in our columns. Then comes a chapter on galvanic batteries, containing a large amount of interesting matter, but which puts us in mind of a musician who will play ten thousand times ten thousand variations on one theme. It seems to us that inventors of batteries ought to be immured in a desert island. The author does not attempt to give a list of the different batteries, which are generally variations upon a few prominent types. One of the easiest ways to obtain historic immortality is to invent a modification of some battery. There is one sentence we should like to add to this chapter, and we are sure it is an oversight of Mr. Sprague's that it is not in, for he is more than just, he is generous in mentioning the names and giving honour to the workers in the science. Is it not a fact that Sturgeon suggested the amalgamation of plates in batteries, and is not this suggestion one of the most important in the annals of electricity? Sturgeon's name is too little known to the English student; his claims to renown have been systematically overlooked, while many a lesser light is held in esteem. Alas, poor Sturgeon!

There is hardly a question about batteries that will not be solved by reference to this chapter, and we are sure that even those who think they know all about batteries will find something new herein. A very complete discussion of secondary batteries concludes the chapter, and upon the whole the author's conclusions are not very favourable to such batteries.

The remarks as to confusion about poles and plates (p. 174)

Digitized by Google

are very pertinent, but the confusion is simply of a piece throughout the whole subject, both notation and nomenclature being sadly in want of straightening out. We imagine that many readers will look upon the diagram (p. 175) as a species of conundrum. The idea may be admirable, but it is not clearly carried out, and without the letterpress would be unintelligible. Makers of secondary batteries will do well to notice the remarks made in this part of the work, such for example as the space that must be allowed for the dilute acid, a given weight of lead requiring a given weight of acid for its conversion. This acid occupies a certain area, so that it would be wrong to attempt to pack too much lead into a given space. The proportions should be retained, giving indeed a little too much acid rather than too small a quantity. We have already said that Mr. Sprague's conclusions are unfavourable to such batteries. His words are :—"It is almost certain that, on the average, the use of storage batteries means the loss of 50 per cent. of the energy, as compared with direct working. This means doubling the cost irrespective of the value and expense of the battery itself; it is as though only one half of the gas put into a gasholder could be delivered from it, and this is why secondary batteries have come into little use, notwithstanding all that was hoped from them." This view differs from the view we hold, which is that hitherto the secondary batteries in the market have not been altogether trustworthy; the plates have buckled, short-circuited, disintegrated, and played other pranks, which experience and care in the manufacture is only now overcoming. In some cases, indeed, no fault has been found; on the contrary, the highest praise is accorded, and, after all, this experience of use is the only one which will be considered. There is much in the next few chapters we should like to specialise, but must pass on. These chapters deal with Measurement, Current, Conductivity and Resistance, Electromotive Force, Electrolysis, Electro-metallurgy, and Terrestrial Electricity, bringing us to Chapter XII., treating of Electro-Magnetism. It hardly need be said that the chapters so summarily passed over contain a vast amount of as important information as any in the work.

The latter part of the book deals with the applications of electricity which have been so rapidly developed during the past few years, such as electric lighting and telephony. Here we find discussed the principles upon which dynamo machines are built, and arc and incandescent lamps manufactured. Here, too, are discussed principles upon which the success and the economy of such lighting are founded, and some very remarkable details and tables relating to cost are given. The conclusion of the author (p. 582) is that electricity will not supersede gas, except in certain favoured localities and under certain favourable conditions.

The work concludes with a dictionary of terms and a good index.

We have been compelled considerably to shorten our notice of this work owing to exigencies of space and time, but we hope we have sufficiently indicated that in our opinion it is a work absolutely necessary for every student of electricity. There is no other book of the kind with which to compare it. Just as Clerk-Maxwell's book stands alone, so must this. The ordinary school book cannot be classed with either; and therefore, when we speak of Mr. Sprague's book standing alone, we do not intend to speak slightingly of some of the excellent books issued for school purposes. His book is not written from such a standpoint, and would not be altogether suited for school work, although it ought to be supplementary thereto. The tenets held by Mr. Sprague are undoubtedly gaining ground, and therefore demand the closest attention from every student desirous of becoming acquainted with the tendency of scientific thought.

The mere mention of the fact that the work is published by Messrs. Spon will be a guarantee that the printing and mechanical get-up of the book is well done.

Numbers of "The Electrician" Out of Print.—Vol. I., Nos. 3, 9, and 19; Vol. VII., 1, 4, 6, 8, 10, 12 to 18, 20, 21, 24, 25, 26; Vol. VIII., 1, 3, 6 to 26; Vol. IX., 2, 3, 4, 9, 17, 19, 24 to 26; Vol. X., 2, 13, 16, 19, 26; Vol. XI., 18; Vol. XII., 3, 8, and 10.

TRAM-CARS WORKED BY ACCUMULATORS IN BRUSSELS.

The Compagnie Belge et Hollandaise d'Electricité, that lighted the Venloo Station, Holland, with thirty-two 2,000-candle Brush and seventy Swan lamps, and will shortly light the Grand' Place, Brussels, has for some time been experimenting with the application of Faure accumulators to tramway traction. The manager, M. Julien, and the secretary, M. Allard, consider that they have solved the problem by employing electromotive force and quantity, according to requirements, which they effect by coupling together several batteries of elements in series or in parallels at pleasure.

The accumulators measure 17½ by 12 centimetres, or 6¾ by 4¾in. The positive plate, 4 millimetres thick and weighing 739 grammes = 26oz., has the interstices filled with red lead; and the negative, 3 millimetres thick, and weighing 568 grammes = 20oz., has the interstices filled with litharge. The weight of lead is 1,234½ kilogrammes = 24cwt. The dynamo, a Siemens D2, is placed under the floor of the car, at right angles to its central line, the car, which carries 40 passengers, weighing as fitted about five tons. The 108 accumulators, placed under the seats from the outside (though they can be charged without removal), may be grouped in series of 40, 54, 66, 80, 95, or 108, by merely shifting a lever on a toothed sector, like the reversing arrangement of a locomotive. A new switch has been devised by M. Allard, in which—supposing the number of secondary batteries to be four, of 27 elements each—all four can be coupled in series, or two in series of 54 each and two in parallel, or three in series and one in parallel, or all four in parallel. The brushes are reversed or taken off by another lever, also working on a sector, but horizontally; and reversing would be sufficient to stop the car on a heavy gradient if the brake should fail. Motion is communicated by belt from a pulley on the dynamo shaft to another on a transmission shaft, a spocket wheel on which engages with an endless chain that turns one of the axles. There are means for tightening up both the belt and the chain; and the axle revolves once for every ten of the dynamo. The car is under perfect control, can be worked forwards or backwards—as little as 10 centimetres or four inches at a time, if required—and may be driven from either end. Only one set of levers is used, however, to prevent the possibility of the wires being made red hot through both ends being worked at once; but when properly worked there is no resistance. An Ayrton and Perry voltameter, in a shunt circuit from the poles of the dynamo, permits of the electromotive force being measured at any moment; there is also an ampereometer by the same makers. The car is provided, in addition, with four incandescence lamps, two inside and two outside, supplied from the accumulators.

The experimental tram-car, which was first tried on the level portions of the Brussels tramway system, mounted one after the other the very steep gradients, combined in some cases with sharp curves. It was at length considered a great feat to ascend from the Gare du Midi, by the Porte de Hal, to the Porte de Namur, which included a gradient of 1 in 26 combined with a curve of 150 metres, or 7½ chains radius, and followed by another gradient of 1 in 21, partly on the straight and partly on a curve of 315 metres = 17½ chains radius. It was considered a still greater feat to come to a standstill on the combined curve and gradient, and then start again; but there yet remained the gradient of 1 in 16 in the Boulevard Botanique to surmount. One day M. Petit, the works manager who made the first accumulator under M. Faure's directions, was so confident of success that he wrote to the general manager that he was going to attempt it, and fearing that his intention might be frustrated, he started out at 4 o'clock the next morning before he could receive a reply. The ascent was made without difficulty; and afterwards, in the presence of the tramway officials, not only was it repeated, but the car was stopped and started again four times on the gradient of 1 in 16. This was deemed a conclusive proof of success from a technical point of view; and to show their confidence of commercial success, the directors of the electric company proposed to work a couple of branches, each

Digitized by Google

about a mile long, for a period of six months, in return for the amount that would otherwise be expended in horse traction. The agreement was signed one day last month, and will come into operation on 1st July for the Rue de la Loi, and shortly afterwards for the Rue Beliard. Instead of transforming the cars, the company will construct a few trucks and fit them with accumulators and dynamos to draw one or two cars after them, the trucks themselves serving to carry small parcels or a few passengers. Indeed the electric company's engineers are sanguine enough to believe that the goods or passengers carried by the trucks will pay expenses, while the cars make the profit. Without presenting any very great difficulties, or a gradient heavier than 1 in 30, the two lines arranged for trial on the scale of actual working are sufficiently uneven to thoroughly test the system. It may be hoped that the commercial success will be on a par with the technical success already achieved.

J. W. P.

SECONDARY BATTERY PATENTS IN THE STATES.

The following is the decision of the Examiner of Patents in the action and claim for priority to the cellular plate for secondary batteries by Swan and Brush. We give the report exactly as it has reached us from America :—

The invention in controversy is as follows :

"A perforated or cellular plate for secondary batteries having perforations or cells extending through the plate and the active material or the material to become active packed in said perforations or cells substantially as described."

In June, 1881, Brush filed a series of applications for improvements in secondary batteries including the case I in interference. This application relates primarily to electrodes, or plates having an active coating of metallic lead mechanically applied. The drawing, as originally filed, showed several forms of plates, treated in this manner, including a flat sheet of lead with a coating of active material pressed thereon and secured in place by a sheet of cardboard, felt, or other equivalent substance ; also a corrugated plate and a ribbed plate with the corrugations or depressions filled with spongy material and mechanically pressed in place.

These plain, corrugated, and ribbed plates were the only examples of the application of the invention shown and described in the specification and drawings, and the claims as originally filed appear to have been limited specifically to these or equivalent forms of the invention. The specification, however, contained a general statement that the described method was particularly applicable to the plates shown in cases B and C.

In case B were shown and described various kinds of corrugated plates, and in case C various kinds of ribbed plates, including perforated plates. The various cross references in these applications were deemed objectionable by the examiner, and the applicant was required to so amend the applications that each should be complete in itself. Accordingly, June 1st, 1882, the applicant filed an amendment, introducing into this case I another sheet of drawings showing perforated plates like those shown in case C, the perforations being packed with porous material.

The interference was originally declared under the title of Swan *v.* Brush, Brush being given the filing date of his original application. This action was based upon the theory that although case I, as originally filed, did not show or describe the perforated plate packed with porous material, the invention was inferentially included therein by the reference to case C. The interference was decided upon the record in favour of Brush by the Examiner of Interferences, no testimony having been submitted by either party. Upon appeal the Examiners-in-Chief reversed this decision, holding that the invention was not included in Brush's application until June, 1882, when he filed the amendment and supplementary drawings, showing and describing specifically the perforated plates. Upon appeal to the Commissioner this decision of the Board was reversed, the Commissioner ruling that Brush was entitled to a record date as of the date of his original application. Upon rehearing, however, it was held by the Commissioner that while the papers in case I, as originally filed, might give authority for the admission of the amendment of June, 1882, the filing of the amendment must give the record date of the invention so introduced into the application under the ruling in the case of *ex parte* Snyder, 22, O. G., 1975. The language of the decision is :

"It is evident that Brush's application clearly illustrating and describing the invention was not filed until the figure illustrating that form of invention had been added to the drawings and a full description had been introduced into the specification. With this understanding of the case, and in the absence of all other testimony, Swan, having been the first to file his complete application within the meaning of Rule 38, must be deemed the prior inventor."

Upon a further motion to rehear and set aside this decision, the Commissioner declined to depart from the position before taken that Brush's application was not complete before the filing of the amendment in June, 1882. Upon the representation, however, of Brush that he would be able to show by parol evidence that he in fact made the invention thus introduced into his application before the record date of Swan, all the decisions in the case were set aside and the case was remanded to the Examiner of Interferences for the purpose of allowing the parties to take testimony in support of their respective claims, the burden of proof in this new proceeding being placed upon Brush. Brush has introduced in evidence the series of applications to which reference has been made, and has also introduced testimony in support of his claim.

So far as his claim to priority of invention rests upon the disclosure furnished by the applications in question, it may now be regarded as definitely settled by the decision of the Commissioner that these applications did not of themselves, as originally filed, and without further explanation, distinctly disclose the invention in controversy. There was not in the range of these applications, as originally filed, a drawing showing a perforated plate packed with porous material, nor was there in all the specifications any distinct description of such invention. The specification in case I referred generally to the various forms of plates shown in cases B and C as suitable for being packed with porous material according to a method therein described ; but in illustrating the proposed invention, the applicant selected from the variety of plates shown in these cases the corrugated and the ribbed or honeycombed plates, thus limiting by these specific examples the more general language of the description.

This interference does not involve broadly the mechanical appliances of porous material to electrodes or plates, but a special improvement in the form of plates so treated. It would be a mere inference to conclude that Brush at the time he filed this application had distinctly contemplated the invention in controversy. As the burden of proof in this case rests upon Brush to show by undoubted evidence that he made this invention prior to the filing date of Swan, it is necessary to resolve any reasonable doubt, such as naturally arises under the circumstances named, in favour of Swan.

The testimony offered by Brush fails to remove the doubt which arises upon the face of the papers. Brush does not state specifically that he at any time invented the subject-matter in controversy. He states that he made drawings showing the invention on or about May 1st, 1881. This allegation, however, must be understood in connection with the facts and circumstances as developed in the testimony. He states that he prepared the original applications, and understood that the cross references in the various applications were equivalent to introducing into each case all that had been described in the other cases. In all this, however, there is no positive statement that he ever contemplated as a matter of fact the treatment of the perforated plate in the manner described. In his own testimony he does not detail the history of his invention further than is involved in the preparation of the applications. He testifies that at least a month before the applications were filed he made pencil drawings for the draughtsman to copy in preparing the applications, adding that several of these drawings fully illustrated the subject matter involved in this controversy. These drawings are not produced in evidence, nor are they described. It appears, however, that they correspond substantially with the drawings originally filed with the specifications, as it is agreed that the drawings were prepared from these sketches. As has been seen, however, the drawings as originally filed did not contain any figure showing a perforated plate packed with porous material.

Brush testifies, it is true, that the drawings filed in cases C, D, and E were copied directly from these sketches. The drawings, however, in cases C and D do not show the invention in controversy. Case E, which has since become patent 274,082, does show perforated sheets packed with porous material. It appears, however, from the record of the case that these drawings were filed as an amendment in June, 1882, and it was admitted by counsel at the hearing that they were made in Washington in June, 1882. It is clear, therefore, that these particular figures were not prepared from the sketches, or at least there is no competent evidence that they were so prepared. It is not shown that the sketches were preserved, or that they were forwarded to Washington. The testimony of Engel on this point must be regarded as a mistake, and as given under a misapprehension of the facts of the case. I fail to see that the testimony advances Brush's case beyond the point before reached. It does not appear that at the time the applications were filed he had made any drawings showing the invention, or that he had disclosed to any one, in conversation or otherwise, the fact that he had made such an invention. The drawings themselves do not even suggest the invention, and there is no evidence that Brush did anything else in connection with this invention except to prepare the applications in question, which, as originally filed, fail upon examination to distinctly describe the invention.

In the meantime Brush must be charged with a knowledge of the art disclosed by Swan's British patent 2,272, of 1881, which was published in this country in the fall of 1881. This patent disclosed to the public full information of the invention in controversy, and it was not until the following year, and presumably after he had been informed of the invention therein contained, that Brush filed the amendment of June, 1882, for the first time illustrating and describing a perforated plate packed with porous material. To overcome the force of the prior publication of the invention it is necessary for Brush to show beyond a reasonable doubt that he had, before the date of the patent, perfected and used the invention, or that, having conceived of the invention before that time, he was using all reasonable diligence in adapting and perfecting the same. The proof of a prior invention to anticipate a prior completed invention or a patent or a printed publication should undoubtedly be clear and positive, both as to the fact of the invention and its reputed date. The only evidence offered in support of his invention to sustain the burden of proof thus placed upon him is the record of these applications and prior sketches alleged to have been made ; the prior sketches, however, are not introduced in evidence. The whole case of Brush is an inference from the remark in case I that the method therein described was applicable to the plates shown in cases B and C ; that he, in fact, proposed to treat the perforated plates shown in case C by the method in case I. The force of this inference is very much weakened by the absence of any positive testimony by Brush while on the stand to the effect that he had made such an invention. At the time the testimony was

Digitized by Google

taken the counsel were well aware of the position of Brush's case. The reopening of the case was upon the express understanding that Brush would introduce positive testimony to show that he had made the invention in controversy at least as early as the time of his application. Even if it be presumed that the idea in fact suggested itself to Brush that the perforated plate of case C might be subjected to the treatment described in case I, it is clear that he did not attach any importance to that suggestion, and certainly did not consider it of sufficient significance to specifically illustrate or describe it in the applications which he filed. In this view the suggestion would appear to be a mere random conception which was never followed up or esteemed of any particular value, which left no traces in actual performance, and whose very existence at the time is problematical. I must conclude, from a careful review of the whole case, that Brush has failed to sustain the burden of proof, or, in the language of the Commissioner, "has failed to show that he made the invention prior to the filing of Swan's application." Swan is therefore adjudged the prior inventor.

Limit of appeal, twenty days.

PATENTS, DESIGNS AND TRADE MARKS ACT, 1883.

IN THE MATTER of Letters Patent granted to FREDERICK JOHN CHEESBROUGH, of 15, Water-street, Liverpool, in the County of Lancaster, Consulting Engineer, for an Invention of "IMPROVEMENTS IN AND RELATING TO ELECTRIC LAMPS, AND TO A METHOD OF CHARGING SUCH LAMPS WITH AN ARTIFICIAL ATMOSPHERE AND PURIFYING THE SAME, AND TO THE PRODUCTION OF A CARBON FOR USE IN ELECTRIC LAMPS, AND FOR OTHER ELECTRIC PURPOSES," dated 28th November, 1878, No. 4847.

NOTICE IS HEREBY GIVEN, that an application has been made by JAMES YATE JOHNSON, of No. 47, Lincolns Inn Fields, in the County of Middlesex, Gentleman (to whom the said Letters Patent have been assigned), under Sections 18 to 21 of the Patents, &c., Act, 1883, and Rules 48 to 56 of the Rules made thereunder, for leave to AMEND the SPECIFICATION filed in pursuance of the said Letters Patent.

Full particulars of the proposed amendment are published in No. 44 of the Official Journal of the Patent Office, and the Specification as proposed to be amended can be inspected at the Patent Office.

Any person intending to oppose such application must leave particulars in writing of their objections to such proposed amendment at the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C., within one calendar month from this date.

Dated this 3rd day of June, 1884.

H. READER LACK,

A PRACTICAL TREATISE ON ELECTRIC LIGHTING.
BY
J. E. H. GORDON, B.A., M.S.T.E.,

Member of the International Congress of Electricians, Paris, 1881; Manager of the Electric Light Department of the Telegraph Construction and Maintenance Company; Author of "A Physical Treatise on Electricity and Magnetism," &c.

"WITHOUT DOUBT IT IS THE MOST VALUABLE WORK ON ELECTRIC LIGHTING THAT HAS YET APPEARED."—*The Electrician.*

"The student of electricity and the electrical engineer will find this a very able and useful work. It is all that it claims to be, 'a practical treatise,' and yet the subject is treated in a thoroughly scientific manner throughout."—*Sheffield Independent.*

London: SAMPSON LOW, MARSTON & CO., 188, Fleet Street, E.C.

Just Published.
With 135 Illustrations. 494 pp. Crown 8vo. Cloth, 15s.

A HANDBOOK OF ELECTRICAL TESTING,
BY
H. R. KEMPE, M.S.T.E., Assoc. M. Inst. C.E.
Third Edition.
London: E. and F. N. SPON, 16, Charing Cross.
New York: 35, Murray-street.

Just Published. Crown 8vo., cloth, 15s.

ELECTRICITY: ITS THEORY, SOURCES, AND APPLICATIONS.
By JOHN T. SPRAGUE, Mem. Soc. Tel. Eng.
Second Edition, Revised and Enlarged, with Numerous Illustrations and Tables.

NOTES.

CABLE REPAIRED.—The cable between Maranham and Para is repaired.

DEATH OF MR. SABINE.—Mr. Thomas Richard Sabine died at Southsea on the 7th inst. at the age of 74 years.

"THE GREAT EASTERN."—It is not improbable that this vessel may be used as a hospital ship in the Thames.

THE TELEPHONE IN JAMAICA.—An exchange is to be opened at Kingston, Jamaica, by the West India Telegraph and Telephone Company.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 6th inst. amounted to £3,029.

THE HASTINGS ELECTRIC LIGHT COMPANY.—We believe that the management of this company is to be handed over to the Hammond Company for two years.

MUNICH.—It is said that the municipal authorities of Munich are in treaty with Mr. Schuckert, of Nürnberg, for the lighting of several streets in their town.

NEW BOOK.—We have received a copy of the third edition of "Telegraphy," by W. H. Preece, F.R.S., and J. Sivewright, M.A., published by Messrs. Longmans, Green, and Co.

HENLEY'S TELEGRAPH WORKS COMPANY.—This company's City offices, at No. 8, Draper's-gardens, E.C., are now in connection by telephone with the works at North Woolwich.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of May, 1884, amounted to £51,537, and to £42,960 in the corresponding period of 1883.

SOCIETY OF CHEMICAL INDUSTRY.—This society will hold its annual meeting in Newcastle-on-Tyne on the 9th, 10th, and 11th of July. The president will be Mr. Walter Weldon, F.R.S.

GOVERNMENT TELEGRAPHS IN AMERICA.—The Bill offered by the Senate Committee on Post Office and Post Roads proposes competition between the Government and private companies.

LONDON AND DERBY ELECTRIC WIRE COMPANY.—A petition for the winding up of this company was presented on the 6th instant, and will be heard before Mr. Justice Chitty on the 21st inst.

"THE ELECTRICIAN'S POCKET BOOK."–Under this title Messrs. Cassell and Co. are about to publish a translation by Mr. Gordon Wigan, M.S.T.E. and E., of M. Hospitalier's "Formulaire Pratique de l'Electricien."

WESTERN ELECTRIC COMPANY.—This company, whose rise and progress we briefly sketched in a note in our last issue, have established an office at 59, Moorgate-street, E.C., where their manufactures can be inspected.

FAURE ACCUMULATOR COMPANY.—A petition for the winding up of this company was presented on the 3rd inst. by several shareholders, and is directed to be heard before Vice-Chancellor Sir James Bacon to-day (Saturday).

NOTICE OF REMOVAL.—The Hammond Electric Light and Power Supply Company have removed their offices from 110, Cannon-street, E.C., to their works, Appold-street, Finsbury, E.C., close to the Broad-street Railway Station.

SCIENCE IN FRANCE.—The French Association for the Advancement of Science will hold its annual congress at Blois under the presidency of M. Bouquet de la Grye, Member of the Institute, on the 4th to the 11th September next.

THE TELEPHONE IN PROVIDENCE (U.S.).—The Providence (Rhode Island, U.S.) Telephone Company had 2,812 subscribers on the 13th May last, an increase of 409 on the previous year. The company has nearly 1,900 miles of wire in use.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 6th June, 1884, were £2,359, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

WALSALL AND THE ELECTRIC LIGHT.—The Walsall Town Council have agreed to the request of the Incandescent Electric Lighting Company for a further extension of time for depositing capital under the electric lighting provisional order relating to this town.

THE TELEGRAPH AND TELEPHONE IN VICTORIA.—News from this colony says that Mr. Berry has decided to leave to the new Postmaster-General the consideration of the questions of reducing the price of telegrams and the proposed purchase of the telephone system.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half-month ended the 31st May are £3,205, as compared with £3,048 in the corresponding period of 1883. The February receipts, estimated at £5,408, realised £5,548.

EARTHQUAKES.—A rather severe shock of earthquake, lasting six seconds, was felt on Friday, June 6th, at Aleppo. No loss of life or serious damage is reported. The direction of the shock was from east to west. On the previous morning two slight shocks were felt at Smyrna.

ELECTRIC LIGHTING IN PARIS.—During the recent Fête de la Presse, given in the Bois de Boulogne on the 7th and 8th instant, the Edison Company lighted the ball room, restaurant, &c. Fifty-five A lamps and 60 B lamps were used. The lighting is said to have given great satisfaction.

ELECTRIC LIGHTING IN MILLS.—The Anglo-American Brush Electric Light Corporation have received an order from Messrs. Illingworth and Sons, of Whetby Mills, Bradford, Yorks., for a No. 7 Brush arc machine and fifteen 2,000 candle-power Brush arc lamps, to be used for lighting their spinning mills in that town.

ANOTHER ATLANTIC CABLE.—The *Anglo-Brazilian Times*, in its issue of May 15, has the following notification: "His Imperial Majesty has consented to entitling the D. Pedro II. American Telegraph and Cable Company, the company formed to connect Ceará by a telegraph cable with the United States."

MAGNETO AND DYNAMO MACHINES.—Mr. J. A. Fahie's pamphlet of 53 pp., describing the various kinds of dynamo machines that have been constructed, has reached a second edition, and has been revised and enlarged by the author. It is published by Mr. J. Falconer, of Dublin, and Messrs. Spon, of Charing-cross, S.W.

AN ELECTRIC LIGHTING CASE.—The proprietors of the Royal Lyceum Theatre, Edinburgh, have refused to pay the bill, of £1,700 odd, presented by the Jablochkoff Electric Light Company for an installation effected in that theatre

Digitized by Google

some time since. The case is to come before the Court of Session on the 3rd July.

INDUCTION.—On Friday week, at a meeting of the Royal Institution, Mr. Willoughby Smith read a paper in which he referred to some peculiar inductive results that he had obtained, results which did not agree with some which had been described by Faraday. We hope to be able to refer to this paper in greater detail later on.

THE FRENCH ACADEMY OF SCIENCES.—M. Jamin has been elected life secretary of this academy in the place of M. J. B. Dumas, deceased. M. Jamin obtained 39 votes, against 12 given for M. Vulpian, and 1 each for MM. Blanchard and Daubrée, the total number of voters being 53. M. Jamin's election leaves a vacant place in the physics section.

THE TURIN EXHIBITION.—A portion of the Turin Electrical Exhibition, consisting of the *salon* of Signor Nigra, is to be lighted by means of one of the Anglo-American Brush Corporation's D_2L Victoria machines working 125 Victoria 20 candle-power incandescent lamps. The recent improvements in the manufacture of this lamp have given it great durability and equality.

FRENCH OPERATORS.—The Friendly Association of French Postal and Telegraph *Employés*, which already numbers 1,500 members, held their annual dinner on Sunday last in the Grand Hotel, Paris. The chairman was M. Guillebert, president of the association, and he was supported by M. Cochery, Minister of Posts and Telegraphs, and M. G. Cochery, nephew of the Minister.

TELEGRAPH MATERIALS WANTED.—The Highland Railway Company require tenders for the supply of galvanised wire, telegraph instruments, and fittings for one year from 1st July. Forms of tender can be had on application to Mr. J. G. Bulmer, storekeeper, Inverness. Tenders addressed to the directors must be lodged with the secretary, Mr. A. Dougall, Inverness, by the 21st instant.

INTERNATIONAL TELEGRAPHIC MONEY ORDERS.—A convention for the establishment of a new system of telegraphic postal orders has been agreed to between the French Government and that of the Grand Duchy of Luxembourg. The payee, says the *Daily News*, receives at his house an advice by telegraph to the effect that the money due to him will be paid on application to the postal authorities.

THE TRANSMISSION OF POWER.—Experiments on the transmission of power will take place between Paris and Creil in September next. Endeavours will be made to transmit 100 horse-power to a distance of fifty kilometres by means of dynamo machines. The firm of Rothschild will defray all expenses in connection with these experiments, which will be carried out under the superintendence of M. Marcel Deprez.

GOLDEN STREETS.—The well-known French electrician, M. Louis Maiche, has found that there is gold to be obtained from the quartz with which the roads round Paris are paved. M. Maiche has extracted small quantities of the precious metal by crushing the stone and treating it with mercury. We have not yet heard of the formation of a company for working the streets of Paris to obtain this gold, nor do we suppose that there will be much of a rush for the new "diggings."

NEW HOUSE OF PARLIAMENT AT BERLIN.—The electric light is to be employed in the new German House of Parliament, the foundation stone of which was laid at Berlin by the Emperor William on the 8th instant. The telephone will also be employed throughout the building. As the work of erection is estimated to take six to eight years it is probable that considerable advances will have been made in both electric lighting and telephony before the wires for either system have to be laid.

UNDERGROUND WIRES IN CHICAGO.—The Chicago Sectional Electric Underground Company obtained a preliminary injunction towards the end of last month restraining the City of Chicago, the Baltimore and Ohio Telegraph Company, the Commissioner of Public Works, and the Baltimore and Ohio Railroad Company from laying telegraph conduit pipes under Jackson or La Salle-street, on the ground that a monopoly of underground telegraph business was given to the company by a city ordinance.

ELECTRIC LIGHTING IN BERLIN.—The Anglo-American Brush Electric Light Corporation have recently supplied to their agent in Germany, Herr Pleive, of Berlin, two of their D_2 Victoria machines, one B_2, and a No. 8 forty-light Brush arc machine. The two D_2 and the No. 8, together with a No. 5 Brush machine, which they are about to supply, and which is to work a single powerful light, are to be employed for lighting the Hygienic Exhibition at Berlin by means of their Victoria lamps and forty of the new Brush-Sellon lamps.

SAFETY LAMPS.—Two models of safety lamps have been adopted by a committee nominated by the Prefect of the Paris Police to report upon the best lamp for use in a gaseous atmosphere. One of these is an electric lamp supplied with current by an accumulator, and the other is an improved Davy lamp. The Paris firemen are to be supplied with these lamps without delay. This action of the Prefect has been taken with a view to prevent similar accidents to that which happened in the Rue St. Denis a short time since, whereby several firemen lost their lives from an explosion of gas.

ELECTRIC LIGHTING IN FRANCE.—The Edison Company, of Paris, have lighted the factory of Messrs. Dubois, Charvet, Colombier and Co., at Armentières, with 200 A lamps. They have also installed 25 A lamps in the Lens Mines, and Messrs. Masurel Brothers, of Tourcoing, who have been using 60 lamps for the last year, have just given orders for 200 more. Baron Alphonse de Rothschild is going to have 120 A lamps fitted up in the Chateau de Ferrières; the same number are to be placed in M. Menier's Hôtel, and Messrs. Parfait and Dubois, of Avesnes, will have 200 in their factory.

ROYAL SOCIETY.—A *conversazione* was given by this society at Burlington House, Piccadilly, on Wednesday evening. There was, as usual on these occasions, an interesting exhibition of scientific apparatus. Amongst other things was an artificial cable exactly corresponding in resistance and capacity to the Mackay-Bennett Atlantic cable, part of which has just been laid by Messrs. Siemens Brothers. Muirhead's system of duplex working and Sir William Thomson's recorders were shown in connection with this, and the working of the line illustrated thereby. Thomson's wave motion machine and double pendulum apparatus, Stroh's curve writer, and other apparatus were also shown.

ELECTRICITY: ITS APPLICATION TO MOTIVE POWER.—Last month Mr. A. Reckenzaun, C.E., gave a lecture before the Clerk of Works Association on "Electricity: Its Application to Public Works and Buildings—Motive Power," which has been reprinted *in extenso* in the *Journal* of this association. In this lecture Mr. Reckenzaun says: "Two pounds of zinc will,

Digitized by Google

in a well-arranged battery, produce energy equal to one horse-power for one hour. Two pounds of coal in a well-arranged steam engine will also yield one horse-power for one hour. But the two pounds of zinc cost sixpence at the wholesale price, and two pounds of coal, at the rate of 18s. the ton, cost hardly ·2d., or nearly one-thirtieth of the price of zinc."

TELEPHONE WIRES IN BRAZIL.—The *employés* of the Telephone Company in Rio de Janeiro have great difficulty in keeping their wires intact owing to the constant damage inflicted by the Aasgeier, a large vulture, which is very common in Brazil. This bird, owing to its habit of just skimming the tops of the houses in its flight, frequently comes in contact with the telephone wires, and either breaks or becomes entangled in them. It appears that there is a law against the destruction of this bird, which does useful work as a scavenger, and consequently there is nothing for the telephone people but to grin and bear it. A local paper suggests that they must wait until the Aasgeier learns to avoid the wires. The wait will be a long one we expect.

TELEGRAPH CLERKS' CONFERENCE. — The fourth annual conference of the Postal Telegraph Clerks' Association has just been held at Birmingham, and was attended by delegates from the principal telegraph centres. The question of gratuitous Sunday labour was discussed, and it was unanimously resolved to again bring the matter before the Postmaster-General. In London all Sunday work is paid for as overtime, but in the provinces no extra payment is given for the duty. It is contended that, as the provincial clerks are called on to perform duty on twelve Sundays in the year, they are entitled either to an overtime allowance or an equivalent in annual leave. The women portion of the staff perform no Sunday duty, but are entitled to the same annual leave, and receive salaries equal to many of the male clerks.

ELECTRIC LIGHTING IN THE "HOUSE."—In the House of Commons on Thursday, the 5th instant, Mr. Gray asked the First Commissioner of Works whether the experiments with the electric light had turned out satisfactorily. If so, he thought there might be some extension of that light, and a proportionate reduction in the item of £1,950 for oil lamps.—Mr. S. Lefevre said he was at present considering whether the electric light should not be applied to every part of the House except the chamber in which they sat. He hoped that with the introduction of the electric light the ventilation of the House, which had been complained of by several members, would be improved.—Later on Mr. Guest suggested that telephones should be placed in the members' rooms, so that the earliest information might be obtained through them.—Mr. S. Lefevre said he would ascertain the views of members on the matter.

THE BRITISH ASSOCIATION'S VISIT TO CANADA.—It is understood that about 700 members have signified their intention of taking part in the meeting at Montreal in August next, and that the arrangements are now complete. Excursions have been arranged so as to give members an opportunity to visit different places of interest, to acquire some information respecting the educational system of the country, and as to the resources and capabilities of the various parts of the Dominion. Some will travel by way of Halifax, and visit the maritime provinces and Quebec before the opening of the proceedings, while others will take this part of the journey on their way home. A liberal subsidy has been given by the Montreal Committee towards the passages of qualified members, and it is assumed that persons accepting this subsidy will remain at Montreal during the continuance of the sitting.

DYNAMOS.—A French contemporary says:—"For some time past there has been considerable discussion as to the invention of dynamos. Certain electricians, roused by the undoubted success of the Gramme machine, have hunted up prior rights to his, and have striven to take from his merits. They have opposed him with the Pacinotti ring, Professor Silvanus Thompson having come forward to establish its priority, as we saw not long since. It is not for us to refute opinions like these. The following telegram, sent from Turin this week to M. Gramme, settles the question definitely:—'Exhibitors and organisers of the Turin Electrical Exhibition, dining together, salute Monsieur Gramme, first inventor of practical (*industrielles*) dynamo machines.' Even the compatriots of Pacinotti recognise in M. Gramme the inventor of practical dynamos. This is in our opinion the highest title that the latter can claim, and we heartily join in the sentiment expressed by the electricians of Turin."

ELECTRIC LIGHTING AT A DANCE.—At a dance given on Wednesday, the 11th inst., by Sir George Grove, at Lower Sydenham, the electric light was used to illuminate the various rooms, with great effect. The lamps, 20 Woodhouse and Rawson and Swan, 20 candle-power, 42 volts, were fed by a Newton compound shunt dynamo, driven by a portable engine placed across the road about 100 yards off, and used during the day for sawing wood. As the house is already wired for electric light, all that it was necessary to do was to hang the cable over the road and connect on to the house mains. The rooms were quite cool, and general admiration was expressed at the effect. One of the young ladies present—Miss Chambers—had a small lamp embedded inside some real flowers, the current being supplied by an accumulator in the pocket of her dress, and the effect was exceedingly pretty. The machine, lamps, &c., were obtained from Messrs. Woodhouse and Rawson; and the whole of the wiring and fixing was done by Mr. A. S. Grove, assisted by Mr. R. T. Turnbull.

PRIMARY BATTERIES.—Without wishing to detract from the merits of the 101 primary batteries that have from time to time been patented and brought before the public by ingenious improvers on old forms of cells, we should like to warn our readers that the cant about supplying electricity free of cost, and the highflown statements as to the capabilities of some of these batteries are worth no more than the paper on which they are so freely expressed. Primary batteries may in some cases prove useful as generators of current for a few incandescent lamps, but their utility or otherwise is entirely a question of time and place. To talk about their producing electricity free of cost is to betray an ignorance of ordinary physical and electrical laws which should be quite sufficient to prevent even the general public from swallowing such high-coloured nonsense; whilst many "ifs" crop up in connection with the statement that the residual products can be sold at a profit, which have to be taken into account and seriously reckoned with in plain unvarnished practical work. Primary batteries are useful enough in their way, and there is no need to circulate misleading statements about them to ensure their sale.

ADDITIONS TO THE GENERAL POST OFFICE.—In the House of Commons on Thursday, the 5th inst., there was some considerable discussion on the vote for the Customs, Post Office, and Telegraph buildings.—Sir G. Balfour protested against an increase of £100,000 for telegraph and Post Office buildings being charged to the current revenue, as these buildings would last for many years, and would benefit future generations.—Mr. H. Fowler complained that this vote had rapidly increased

Digitized by Google

in the last few years. He thought that a large amount of money was spent unnecessarily in the erection and alteration of post offices. It was urged in extenuation of the failure to carry out the promise to introduce sixpenny telegrams that the revenue of the Post Office would not bear it. This was a reason why the most rigorous economy should be exercised throughout the country in the erection of post offices. As a matter of protest he moved the reduction of the vote by £10,000.—After alluding to the vast increase in the postal business, which necessitated larger buildings, Mr. Fawcett said that nearly £53,000 out of the £100,000 was required for carrying on the work which would be caused by the introduction of sixpenny telegrams. Without the proposed additional story to the building it would be impossible to meet that increased business.—Eventually the vote was agreed to.

CARDEW'S SYSTEM OF WINDING DYNAMO MAGNETS.—The Anglo-American Brush Electric Light Corporation have just supplied to the order of a Colonial Government one of its D_2 100 light Victoria machines. The field magnets of this machine are wound on the system patented and devised by Captain P. Cardew, R.E., of Chatham, and consist in an arrangement whereby the dynamo can be used for working arc, incandescence, or search lights at will. By means of a simple switchboard placed on the machine it is possible to so connect up the coils of the magnet fields as to allow of four powerful arc lights being worked simultaneously; or if four be not required, three, two, or one may be worked in parallel. By this ingenious method of winding the difficulty of working arc lamps in parallel economically has been surmounted; the arrangement at the same time permits of any of the arc lamps being worked independently of the others. By a simple alteration on the switchboard the machine can also be used for working a single powerful hand-regulated search light of 25,000 candles, suitable for naval or military purposes. As well as this, the machine will maintain 100 20 candle-power 60 volt Victoria lamps, and being self-regulating, these lamps may be turned on and off at will in any required number, without attention being paid to the dynamo, the speed remaining practically constant. Further, by this novel winding of Captain Cardew's, it is possible to work satisfactorily arc and incandescence in parallel simultaneously.

GAS AND ELECTRIC LIGHTING. — In the course of his address as president of the Gas Institute, delivered on the 10th inst., Mr. Robert Harris, M.I.C.E., said:—"This address would probably not be considered complete were I not to make some allusion to the electric light. I have purposely left its consideration till the last, feeling that it has now assumed a position of very minor importance as far as the gas industry is concerned. It has been proved, and, judging by the results as shown in the defunct and moribund companies, proved over and over again, that it cannot compete with gas, as now very generally used, at the prices that rule in England. Notwithstanding the failures which have taken place, we, as gas engineers, must not ignore the fact that there is a source of artificial illumination other than the one in which we are more directly interested, which may come into competition with us, and which doubtless will find its position alongside gas in certain places where its peculiar qualities render it more suitable. It has always struck me that the electric light in the incandescent form is particularly well adapted for use for lighting our large ocean-going steamers. The conducting wires might be laid with great facility all over the ship; the lights would be fixed and shielded, so that the danger from fire would be reduced to a minimum; and, further, ample steam power would always be at hand, to be employed for driving the dynamo machines when required. I am informed that several large ships are now so lighted, and with marked success."

DUNDEE MECHANICAL SOCIETY.—The inaugural address of this society was delivered on the 5th inst., to a large audience, by Professor J. A. Ewing, who took for his subject "The Recent Progress in the Practical Applications of Electricity." After tracing the development of the dynamo machine from the time of Faraday's fundamental discovery, the lecturer discussed at length the question of electric lighting. It was pointed out that the jute and linen mills of Dundee formed a field in which electric lighting could be introduced with advantage. A calculation was given of the cost of lighting a mill with 500 20-candle incandescent lamps, from which it appeared that, provided the requisite power could be obtained from existing engines without other outlay than the cost of the extra coal thereby consumed, the price for electricity would be almost the same as the price of an equivalent light from Dundee gas. In this estimate the interest on and depreciation of the electric plant was taken account of, as well as the renewal of lamps, coal, oil, and attendance. But while the cost would be nearly the same the difference in comfort and health to the workers would be immense. Moreover, the ease and safety with which electric lamps could be put just where they were wanted would enable the same total amount of light to be more advantageously disposed. As an example of this, Professor Ewing cited the case of spinning frames, in which with gaslight the quick detection of a broken thread was difficult. A mill manager had told him that the output of the frames was 7 per cent. less during the winter months, when gaslight was used, than during the summer months, and his informant ascribed this to the difficulty of seeing the threads in gaslight. The lecturer suggested that a possible remedy, worth trial at least, would be to put electric lamps inside the frames, so that the threads would show as dark lines on a bright ground.

THE TELEPHONE AND THE POST OFFICE.—A memorial has been presented to the Postmaster-General by the Edinburgh Chamber of Commerce, asking Her Majesty's Government to grant such facilities as will encourage and develop the telephone system, without unduly interfering with the revenue of the Post Office. In an article commenting on the above memorial the *Edinburgh Courant* attacks the policy of the Post Office in connection with the telephone without stint. It characterises the proceedings of the department subsequent to the compromise between it and the telephone companies as consisting of "vexatious, frivolous, factious interference of every kind." The rent of £10 per mile per annum charged by the Post Office for trunk lines is, our contemporary says, exorbitant, and illustrates "how carefully swaddled in officialism and ingeniously red taped the whole supervision of these trunk wires is." Further on we read that "in every single case in which a Government telephonic exchange has been established, with the solitary exception of Newcastle-on-Tyne, where a moderate success has resulted, the experiment has been a total failure. On the other hand, notwithstanding the restrictions under which the business is conducted, there is no instance of a telephonic exchange carried on by private enterprise being otherwise than a success." The *Courant* concludes as follows:—"It is surprising that a great political economist, such as Mr. Fawcett is admitted to be, should have taken the line he has done. No doubt the permanent heads of the department have a great deal to answer for. Be this as it may, we have no hesitation in saying that

Digitized by Google

very shortly public opinion will be so educated upon the question that the narrow-minded officialism which presently obtains will be swept aside, and the public will be allowed the free use of what is undoubtedly at once the greatest scientific marvel and the most perfect business facility of our time."

GREENWICH OBSERVATORY.—On Saturday last the Board of Visitors of the Royal Observatory at Greenwich paid their annual visit to that establishment to inspect the instruments and receive the report of Mr. W. H. M. Christie, Astronomer Royal, for the year ending 20th ultimo. Several members of the Royal Society also visited the Observatory on the invitation of their president. The following extracts from the report may interest our readers:—The sun has been photographed on 219 days, on only four of which the disc was free from spots; the greater number of photographs compared with former years is due to a great extent to the use of dry plates, as a photograph can be secured now when the sun is visible even for a few minutes. The Greenwich time ball was not raised on two days on account of high wind; on the remaining 363 days it was successfully dropped. The ball at Deal was not raised on nine days, and failed to drop on 16 days owing to failure in the telegraphic connection. Since February 29th this ball has been dropped through the Post Office telegraphs instead of the South-Eastern Railway Company's wires. The Westminster clock has performed satisfactorily, the error being less than one second on 53 per cent. of the days of observation, and over three seconds on only 4 per cent. In the Magnetic Department the time of vibration of the magnets has been so adjusted that the movements recorded on the photographic sheets for vertical force, horizontal force, and declination are directly comparable. There were only five days of great magnetic disturbance in 1883. Tracings of the magnetic registers have been reproduced by photo-lithography to supersede the tables of ordinates in the Greenwich volume of observations. The number of hours of bright sunshine recorded was 1,241, or about 30 hours above the average of the preceding six years. No connection was remarked between magnetic disturbances and the red sunsets of the past winter.

THUNDERSTORMS.—Towards the end of last week severe thunderstorms occurred in various parts of England. On Thursday, the 5th instant, Nos. 1 and 2, Clarendon-villas, Dovercourt, near Harwich, were struck by lightning. Considerable damage was done to the furniture in No. 1, and the basement was set on fire. It may be mentioned also that every one of the fire-stoves in No. 1 were dislodged. No one appears to have been hurt. A storm visited London on the same day at about 2 p.m., during which a man named Fennell, the gate-keeper at Lord's Cricket Ground, St. John's Wood, was struck and rendered insensible for some time. The flash then caught the back room of No. 3, Grove-road, in the rear of Lord's, and filled the room with a sulphurous vapour. In the basement it fused a gas-pipe, and set the gas alight as it escaped. On Saturday during a heavy thunderstorm at Halesowen a woman named Phœbe Harris was killed by lightning. In consequence of the violence of the storm the deceased caused seven children to assemble in the kitchen. She picked up a grandchild, and when in the act of sitting down was struck dead by lightning, and the whole of her hair burnt off her head. The child, which was clasped tightly in deceased's arms, was unhurt. At Great Alne, near Alcester (Warwickshire), Mr. Sidney Bemford, farm bailiff, had his horse killed as he was sitting on it talking to another man. The flash rendered both men insensible for hours. At Chorley (Lancs.) a house in Clifford-street and two houses in Seymour-street were struck, much damage being done to furniture, but no personal injuries resulting. A house at Pemberton was also struck and the chimney demolished. At Hartpury in Gloucestershire a mare and her foal were killed by lightning, and at Longhope near this place a flock of eighteen sheep were killed. On Sunday a house in the Avenue at Clifton, Bristol, was struck and the chimney destroyed, and at Birmingham a Congregational chapel was struck. Here the current appears to have passed half way down the conductor, then forced some masonry out of the wall, caused an explosion of gas, smashed gas brackets near the organ, and hurled a portion of a bracket into the body of the church, striking a man on the back. The watches of the organist and several choristers were stopped, and the organ blower's hat was carried from his head some distance away. A panic was with difficulty prevented. Fortunately no one was injured, chiefly owing to the presence of mind of the minister, who begged the congregation to keep quiet and remain seated.

PRIVATE LIGHTING.—An interesting installation of the electric light has just been completed at Linden Park, near Hawick, the residence of Mr. Walter Laing. Linden Park is about two miles from Hawick, and the house is a new one, only just completed. A small stream—a feeder of the Teviot—runs through the grounds, and advantage has been taken of this to obtain power for producing electricity for lighting the mansion and stables. A turbine wheel has been erected capable of giving off about eight horse-power and requiring about 270 cubic feet of water per minute when working at full power. As the stream will not in dry weather give nearly so much as this, a reservoir, in the shape of a small lake of about an acre in extent, has been constructed in the bed of the rivulet. In the driest weather the stream may be depended upon to give at least 80 cubic feet per minute, and this being stored up in the reservoir during the daytime, more than sufficient force is obtained for working the turbine when the lights are required at night. The turbine is fixed in a small building, and is connected by a short belt with the dynamo, which is a Siemens compound self-regulating machine, capable of supplying about 70 Swan incandescent lamps of 16 candle-power each. From the dynamo the necessary conducting wires are carried up to the house, partly on posts overhead and partly underground, branches being taken off to supply the stables and the avenue from the lodge. About 100 Swan incandescent lamps have been fitted up altogether, and of these 70 can be worked at once, and all or any can be turned on or off at pleasure. Most of the lights are of about 16 candle-power, but a few are 32. About 80 lights are distributed through the house, lighting every portion, no other kind of light being provided for. Seven lights are taken up in lighting the stables, and 12 outside. These latter are all controlled by one switch near the hall door, and can either be lighted or extinguished instantly. The distance of the turbine and dynamo from the house is about 350 yards, and from the house to the lodge about 400 yards. For stopping the turbine at night when the lights are no longer required a simple electrical arrangement has been designed, by means of which the sluice valve can be closed from the house without going down to the turbine house. The whole of the electrical portion of the work was entrusted to and successfully carried out by Messrs. J. Edmundson and Co., electric light engineers, of 19, Great George-street, Westminster, S.W. This is a good specimen of the class of work which could readily be carried out at many country houses, and we have no doubt that as the convenience and healthy properties of the incandescent system become more generally known similar installations will be common.

ELECTRO-CHEMISTRY.—Inorganic.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 78.)

Separation of Zinc. — Zn. Electro-chemical equivalent $=\frac{65}{2}=32\cdot5$. A dyad cation. Only the most highly positive metals usually set free zinc from its solutions. From slightly acid solutions of zinc salts magnesium deposits the metal and hydrogen gas (Roussin, *Chem. News.*, Vol. XIV., p. 27). According to S. Kern, magnesium evolved hydrogen very slowly from a solution of zinc chloride (*Jour. Chem. Soc.*, 1876, Part I, p. 684). Sodium amalgam immersed in a concentrated solution of zinc sulphate forms a viscid amalgam of zinc (Böttger, Watts's "Dictionary of Chemistry," Vol. III., p. 891). Joule also obtained amalgams of zinc by electrolysis, using a cathode of mercury (*ibid*). From an alkaline solution of a salt of zinc aluminium easily separates the metal (A. Cossa, Watts's "Dictionary of Chemistry," Vol. VII., p. 54). I observed that in a solution of either nitrate, chloride, sulphate, or acetate of zinc neither antimony, bismuth, platinum, gold, silver, copper, brass, German silver, nickel, iron, tin, lead, or zinc becomes coated with zinc by simple immersion. I heated a mixture of 1·5 grain of crystals of silicon and 10·25 grains of perfectly dry fluoride of zinc in a porcelain crucible to a full red heat; the salt was decomposed and zinc set free. According to V. Roque, wrought and cast iron previously dipped in a strong solution of potassic carbonate, became coated with zinc by simple immersion during from three to twelve hours in a solution composed of 1,000 parts of water, 10 of chloride of aluminium, eight of potassic bitartrate, five of stannous chloride, four of acid sulphate of aluminium, and four of chloride of zinc (*Chem. News*, Vol. XXI., p. 288).

Raoult states that gold or copper in contact with zinc, in a concentrated and boiling solution of chloride or sulphate (but not nitrate) of zinc, acquires a deposit of zinc. But gold in contact with antimony, silver, copper, nickel, iron, or lead, in cold or boiling acid or neutral solutions of salts of zinc, receives no such coating (*Chem. News*, Vol. XXVI., p. 240; Vol. XXVII., p. 59. *Jour. Chem. Soc.*, Vol. XI., p. 464). Copper or brass immersed in contact with zinc in a boiling saturated solution of chloride of ammonium acquires in a few minutes a specular coating of zinc, but in a solution of cream of tartar no such deposit occurs (R. Böttger, "Gmelin's Handbook of Chemistry," Vol. I., p. 50; also *Chem. News*, Vol. XXII., p. 108). Copper acquires a fixed and brilliant coating of zinc by immersing it in contact with zinc in a hot concentrated solution of potash or soda (F. Weil, *Chem. News*, Vol. XIII., p. 2).

By means of a separate current and a zinc anode zinc has been deposited from solutions of several of its salts, viz., the chloride, ammonio chloride, sulphate, ammonio sulphate, acetate, tartrate, &c. According to Smee, a solution of zinc oxide in caustic potash is not a good conductor, the zinc anode does not readily dissolve in it, and similarly with the potassio tartrate and potassio cyanide.

Electrolysis of Chloride of Zinc.—$Zn.Cl_2$. Molecular weight = 136. Fused zinc chloride is reduced to metal by contact with aluminium (Flavitzky, Watts's "Dictionary of Chemistry," Vol. VIII., Part I., p. 64). It has been stated that perfectly clean iron acquires a thin coating of zinc by simple immersion in a solution of 30 parts of zinc chloride and 1 of sal-ammoniac (Watts's "Dictionary of Chemistry," Vol. VIII., Part 2, p. 1,118). According to Grove, nitride of zinc is formed at an anode of zinc in a weak solution of sal-ammoniac (Watts's "Dictionary of Chemistry," Vol. V., p. 1,072).

Electrolysis of Sulphate of Zinc.—$Zn.SO_4$. Molecular weight = 161. Sodium amalgam in contact with a strong solution of this salt forms a viscid amalgam (Böttger). Joule formed the same compound by making mercury the cathode in that liquid. From a solution of the sulphate, magnesium deposits with strong action a mixture of zinc, its hydrated oxide, and sulphate (Commaille, *Chem. News*, Vol. XIV., p. 188.)

By means of a current from two Smee's cells, with a large zinc anode, a solution of one part of zinc sulphate in five to ten parts of water may be made to yield a good deposit of zinc. According to V. Meyer, pure zinc may be obtained by the electrolysis of an ammoniacal solution of its sulphate with a sheet zinc anode and a copper wire cathode (*Jour. Chem. Soc.*, Vol. X., 2nd Series, p. 221; *see* also Watts's "Dictionary of Chemistry," Vol. VII., p. 1,213).

MM. Person and Sire easily deposited zinc "on any metal," by the separate current process, with a single cell and a zinc anode, from a solution of one part of oxide of zinc dissolved in 100 parts of water containing 10 of alum (*Chem. News*, Vol. II., p. 275).

Electrolysis of Cyanide of Zinc and Potassium.—A. Watt makes a mixture composed of twenty gallons of distilled water, 200 ounces of cyanide of potassium, and eighty by measure of the strongest aqueous ammonia. He then fills several large porous cells with a solution composed of sixteen ounces of cyanide of potassium to each gallon of water, and partly immerses them in the other liquid. In the porous cells he places sheets of copper or iron to act as cathodes, and in the outer liquid clean pieces of zinc to act as anodes, and connects the battery in the usual way until about sixty ounces of zinc are dissolved, and then stops the current and removes the porous vessels. He next dissolves eighty ounces of carbonate of potassium in a part of the zinc solution, and returns it to the original portion, and stirs the mixture thoroughly. After the sediment formed has subsided he decants the clear liquid for use. Articles of iron may be coated in this liquid. Anodes of zinc are employed, and a little cyanide of potassium and liquid ammonia are occasionally added if necessary. The battery preferred is composed of two Bunsen cells.

Deposition of Alloys of Zinc and Copper.—As early as the year 1841 M. de Ruolz deposited brass, by means of the battery process, from a solution of the mixed cyanides of copper, zinc, and potassium. One of the best solutions for yielding brass by means of a separate current is that of Morris and Pershouse. It is composed of one pound of potassic cyanide, one of ammonium carbonate, two ounces of cupric cyanide, and one of cyanide of zinc, dissolved in one gallon of water, and the liquid used at 150° F., with a strong current and a large brass anode. To increase the proportion of copper in the deposit, either add potassic cyanide or raise the temperature, and to increase that of the zinc, add ammonic carbonate or lower the temperature. Walenn recommends a solution composed of equal parts of ammonic tartrate and potassic cyanide dissolved in water, and after addition of the cyanides of copper and of zinc the oxides of those metals are also added to the solution. If upon trial hydrogen is set free at the cathode, a little ammoniuret of copper is also added to the mixture. There is then no liberation of hydrogen, and a deposit of brass may be obtained of any desired thickness. Two or three Smee's cells are sufficient (*Chem. News*, Vol. XXI., p. 273, Vol. XXII., pp. 1 and 181; *Jour. Chem. Soc.*, Vol. X., p. 103; and *Phil. Mag.*, 4th Series, Vol. XLI., p. 41). In depositing from an electro-brassing solution, which contains cyanide of potassium and tartrate of ammonium, at a temperature but little above the freezing point, nearly pure zinc forms upon the cathode (Walenn, *Chem. News*, Vol. XXXV., p. 154; see also Watts's "Dictionary of Chemistry," Vol. VII., p. 382).

Deposition of Alloys of Zinc, Copper, and Nickel.—A solution described by Morris and Johnson for depositing German silver is composed as follows:—Dissolve one pound of potassic cyanide and one of carbonate of ammonium in a gallon of water. Heat the solution to 150° F. Immerse it in a large anode of German silver and a small cathode of any suitable metal, and pass a strong current until a large quantity of the alloy has dissolved and a bright cathode receives a good deposit of the desired alloy. If the deposit becomes too red,

Digitized by Google

add ammonic carbonate; if too much of the appearance of zinc, add potassic cyanide.

Various other mixtures for depositing brass and German silver may be found described in works on electro-metallurgy.

For the electrolytic anylysis of compounds of zinc see *Chem. News*, Vol. XXIV., pp. 100 and 172; Vol. XXXV., p. 264; Vol. XLIII., p. 61; Vol. XLIV., p. 304; and Vol. XLVI., p. 105. *Jour. Chem. Soc.*, 1877, Part I., 340, and Part II., pp. 804 and 924; Vol. XXXVIII., 1880, p. 584; Vol. XL., 1881, pp. 1,081, 1,101, and 1,170; Vol. XLII., 1882, pp. 896 and 1,320; and Vol. XLIV., 1883, p. 122. *The Chemist*, New Series, Part XVIII., March, 1855, p. 334. Watts's "Dictionary of Chemistry," Vol. VIII., Part I., p. 712.

For the electro-metallurgy of zinc *see* Luckow, *Jour. Chem. Soc.*, Vol. XLII., 1882, p. 431; and the separation of zinc and silver, by W. G. Blagden, *see* Watts's "Dictionary of Chemistry," Vol. VI., p. 1,026.

Separation of Magnesium.—Mg. electro-chemical equivalent $\frac{24\cdot3}{2} = 12\cdot15$. A dyad cation. Fused magnesic chloride is not reduced to metal by contact with aluminium (Flavitzky, Watts's "Dictionary of Chemistry," Vol. VIII., Part I., p. 64). An amalgam of potassium or sodium decomposes a solution of magnesic sulphate by simple contact, and produces magnesium amalgam. Electrolysis of that liquid into a cathode of mercury also produces it (Klauer, Watts's "Dictionary of Chemistry," Vol. III., p. 888; *Jour. Chem. Soc.*, 1876, Part I., p. 684). I melted to a perfect liquid, at nearly a white heat, a mixture of six grains of magnesic fluoride and four of calcic fluoride, and then added two grains of crystals of silicon. The crystals did not dissolve, and there appeared no signs of magnesium having been separated. The electrolytic decomposition of the double chloride of magnesium and sodium in a fused state by contact with sodium is the ordinary process of obtaining the metal.

(TO BE CONTINUED.)

THE INDUCTION OF CURRENTS IN CORES.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 55.)

The core currents may be allowed to flow or not, by, in the latter case, a suitable division of the core into insulated parts. We then have merely the insignificant currents which the dielectric will permit. We make no count of the heating from this cause, which will be considered later. Also, the alternate magnetisations and demagnetisations occurring in the core are supposed to be of the conservative character, involving no dissipation of energy at all when the currents are not allowed to flow. I do not know whether it has been definitely established that there is a dissipation of energy going on in iron cores apart from the heating as per Joule's law, although I conclude from indirect experiment that if there be any it is not great with moderate magnetising forces. On the above suppositions we may let the currents flow in the core, or stop them completely, as we please, without removing the core. If it be of a non-magnetic metal, with μ practically equal to unity, the effect on the coil current of insulating the core is the same as removing it altogether. But if it be of iron its insulation and removal are of course not equivalent. Put $\rho = \infty$ to show insulation. Put $\mu = 1$ as well to show removal, which will greatly alter the value of L, the coefficient of self-induction where the core is of iron, and not at all if of copper.

Let $L = L_1$, *i.e.*, let the depth of coil be small compared with its radius, let the core fill the coil opening, and let the external self-induction of the circuit be negligible. Allowing the core currents to flow always diminishes the lag of the coil current behind the impressed force, but the amplitude of the coil current may be either reduced or increased according to the speed and other circumstances, especially the resistance of the coil circuit. First, as regards the lag, that ϵ is always reduced may be thus seen. Put in equations (42) the values of P and Q given by equations (39); then

$$\tan\epsilon = \frac{S\,(MN' - NM')}{R\,(M^2 + N^2) + S\,(MM' + NN')},$$

where S stands for $\frac{L_1\rho}{2\pi\mu c} = \frac{2L_1 n}{xc}$. Now use in this the expressions lately given for the M and N functions in the brackets, and we shall find

$$\tan\epsilon = \frac{\dfrac{L_1 n}{R}}{Y_1 + \left(\dfrac{L_1 n}{R}\right)\dfrac{xr^2}{8}Y_2} \quad . \quad . \quad . \quad . \quad . \quad (48a),$$

where Y_1 and Y_2 are two functions whose values are unity when $y = 1$, and whose full expressions are

$$\left.\begin{aligned} Y_1 &= \frac{1 + \frac{2y}{2^2 4^2}\Big(1 + \frac{3y}{6^2 8^2}\Big(1 + \frac{3\frac{1}{3}y}{10^2 12^2}\Big(1 + \frac{3\frac{1}{2}y}{14^2 16^2}\Big(1 + \frac{3\frac{3}{5}y}{18^2 20^2}}{1 + \frac{6y}{4^2 6^2}\Big(1 + \frac{5y}{8^2 10^2}\Big(1 + \frac{4\frac{2}{3}y}{12^2 14^2}\Big(1 + \frac{4\frac{1}{2}y}{16^2 18^2}} \\ Y_2 &= \frac{1 + \frac{6y}{6^2 8^2}\Big(1 + \frac{5y}{10^2 12^2}\Big(1 + \frac{4\frac{2}{3}y}{14^2 16^2}\Big(1 + \frac{4\frac{1}{2}y}{18^2 20^2}}{1 + \quad . \quad . \quad .} \end{aligned}\right\} \quad (49)$$

the denominator in Y_2 being the same as in Y_1. Now it can be easily seen that Y_1 is greater than unity; this fact, since Y_2 is also positive, makes the denominator in (48) always greater than unity; and therefore $\tan\epsilon$ less than $L_1 n/R$, which is its greatest value, occurring when the core currents are stopped.

But, as regards the amplitude of the coil current, if we call the apparent resistance of the circuit R_1, *i.e.*, what it should be for the same impressed force to give the actual current strength if there were no inductive E.M.F., then, by equation (41),

$$R_1^2 = \frac{P^2 + Q^2}{M^2 + N^2} = R^2 + S^2\frac{M'^2 + N'^2}{M^2 + N^2} + 2RS\frac{MM' + NN'}{M^2 + N^2},$$

which, by the given expressions for the M,N functions, may be written

$$\left(\frac{R_1}{R}\right)^2 = 1 + \left(\frac{L_1 n}{R}\right)^2 Y_3 + \left(\frac{L_1 n}{R}\right)\frac{xr^2}{4}Y_4 \quad . \quad . \quad . \quad . \quad . \quad . \quad (50)$$

in which Y_3 and Y_4 are given by

$$\left.\begin{aligned} Y_3 &= \frac{1 + \frac{3y}{4^2 6^2}\Big(1 + \frac{3\frac{1}{3}y}{8^2 10^2}\Big(1 + \frac{3\frac{1}{2}y}{12^2 14^2}\Big(1 + \frac{3\frac{3}{5}y}{16^2 18^2}}{1 + \frac{2y}{2^2 4^2}\Big(1 + \frac{3y}{6^2 8^2}\Big(1 + \frac{3\frac{1}{3}y}{10^2 12^2}\Big(1 + \frac{3\frac{1}{2}y}{14^2 16^2}\Big(1 + \frac{3\frac{3}{5}y}{18^2 20^2}} \\ Y_4 &= \frac{1 + \frac{6y}{6^2 8^2}\Big(1 + \frac{5y}{10^2 12^2}\Big(1 + \frac{4\frac{2}{3}y}{14^2 16^2}\Big(1 + \frac{4\frac{1}{2}y}{18^2 20^2}}{1 + \quad . \quad . \quad .} \end{aligned}\right\} \quad (51)$$

the denominator in both cases being the same. Now here Y_3 and Y_4 are less than unity, which is their value when $y = 0$, and this permits R_1^2 to be either greater or less than $R^2 + L^2 n^2$, the value when the core currents are stopped. In order that R_1 should be increased or decreased by permitting the core currents to flow, we must have, by equation (50),

$$1 + \left(\frac{L_1 n}{R}\right)^2 Y_3 + \left(\frac{L_1 n}{R}\right)\frac{xr^2}{4}Y_4 > \text{or} < 1 + \left(\frac{L_1 n}{R}\right)^2$$

which is the same as

$$\frac{L_1}{R} < \text{or} > \frac{\pi\mu r^2}{\rho}\,\frac{Y_4}{1 - Y_3} \quad . \quad . \quad . \quad . \quad . \quad . \quad (52)$$

Here L_1/R is the time constant of the coil circuit. Its greatest value is when the coil is short circuited, so we cannot increase it as we like; but by inserting resistance we may diminish it indefinitely. Thus L_1/R may be always made less than the quantity on the right side, and should it be greater when the coil is short circuited, we may, according to the resistance we

Digitized by Google

insert, cause the coil current to be either increased or diminished by the reaction of the core currents when the latter are permitted. Noting that Y_4 and Y_3 are fractions which decrease from unity as y increases, that is, as the frequency of the oscillations, and other circumstances before mentioned, making $Y_4/(1-Y_3)$ large when y is small, and small when y is large, we see that in general at low speeds the coil current is likely to be weakened, and at high speeds strengthened by the core currents. The latter effect may be very considerable.

Example 1. *y small.*—Let $y=1$, or $(8\pi^2\mu v r^2)^2=\rho^2$. If the core is of copper, $\rho=1{,}700$, $\mu=1$. Let $c=r=1$ cm., then $8v=170$ gives the frequency required. We find by equations (51),

$$Y_3=\cdot 975, \qquad Y_4=\cdot 972,$$

so that the apparent resistance R_1, by equation (52), is increased by allowing the core currents to flow,

if $\quad L_1/R<(\pi/1{,}700)\div(972/25)$ or 1/15 sec, nearly.

Now, under the circumstances, the time-constant must be less than this value. For, by equations (6) and (9), its greatest value, viz., when coil is short circuited, is given by

$$L_1/R=\pi^2\mu bc^2/c_1^2\rho_1\,(2c+b),$$

in which we must for the present purpose put $\mu=1$. Also $\pi^2=10$, and $c_1{}^2\rho_1$ we may take $=2{,}000$, making

$$L_1/R=bc/400,=b/400,$$

remembering that b must be small compared with c, and that $c=1$. Thus the amplitude of the coil current is in this case reduced by the core currents, whatever the resistance in circuit may be. With the time constant $=\dfrac{1}{4000}$ we find the squares of the apparent resistances as compared with the square of the real resistance to stand in the ratios

$$1:1{\cdot}0011:1{\cdot}0093,$$

the unity being with no core, the second number with self-induction only, the third with core currents also, showing the effect of the latter cause in reducing the coil current to be greater than that of the self-induction alone.

As regards the alteration in the amount of retardation, we find

$$\tan\epsilon=L_1n/R=133{\cdot}5/4000=\cdot 03337$$

with self-induction only; and, by equation (48),

$$\tan\epsilon=\cdot 03337/\,(1{\cdot}0206+\cdot 03337\times\cdot 9922/8)$$
$$=\cdot 03337/1{\cdot}0247=03256$$

when the core currents are permitted to flow. This difference may seem very insignificant, but when two coils are *balanced* against one another far smaller charges are experimentally observable. However, the example is not a favourable one for showing a large difference. If in this example we substitute an iron core, keeping other things the same, with the same value of $y=1$, with a lowered speed to suit the altered permeability and conductivity, we simply multiply the former time-constant by the new value of μ, and we shall find, unless μ is exorbitantly large, that the small value $y=1$ still does not permit the coil current to be increased by the core currents. To get this result we must raise the now lowered speed, give a larger value to y, and we shall find the coil current much increased.

Example 2. $y=40^2$. Iron core.—Let $\mu=100$, $\rho=10{,}000$, $c=1$, and $v=50$. Then $x=40$, and $y=40^2$.

Here we find $M^2+N^2=198{\cdot}25$, showing that the amplitude of the magnetic force at the core's boundary is 14 times that at the axis. We also find

$$Y_1=4{\cdot}454,\quad Y_2=\cdot 176,\quad Y_3=\cdot 089,\quad Y_4=\cdot 039;$$

and these values inserted in equations (48*a*) and (50) give us

$$\left(\frac{R_1}{R}\right)^2=1+\cdot 089\left(\frac{Ln}{R}\right)^2+\cdot 396\left(\frac{Ln}{R}\right)\quad . \quad . \quad . \quad (53),$$

and
$$\tan\epsilon=\frac{Ln/R}{4{\cdot}454+\cdot 881\,Ln/R}\quad . \quad . \quad . \quad . \quad . \quad . \quad (54),$$

where Ln/R may be varied considerably.

By equation (52) the apparent resistance of the coil circuit is increased or reduced by permitting the core currents to flow, according as

$$Ln/R<\text{or}>\frac{\cdot 396}{\cdot 910}=\cdot 42.$$

By our initial supposition, we have $n=2\pi v=100\pi=314{\cdot}16$, therefore

$$L/R=\cdot 42/314{\cdot}16=\cdot 0013\text{ second}$$

is the critical value of the time constant of the coil circuit. Now, if the coil be short circuited, the value of the time constant can be far greater than this. For instance, by the formula for L/R given in the last example, L/R would be $\frac{1}{40}$ sec. if the depth of the coil were $\frac{2}{10}$ of its radius. It would then require a considerable resistance to be inserted in circuit with the coil to reduce the time-constant to ·0013 sec. If still more resistance be inserted, the core currents will weaken the coil current; if less, they will strengthen it. The amount of this strengthening when the coil has little external resistance in connection with it, we may see from equation (53) by taking therein $L/R=\cdot 025$ and $n=314{\cdot}16$. We get

$$\left(\frac{R_1}{R}\right)^2=1+5{\cdot}524+3{\cdot}108=9{\cdot}632=(3{\cdot}10)^2,$$

the coil current being therefore a little less than one-third of the strength it would have were there neither core currents nor self-induction. Now stop the core currents; we have

$$\left(\frac{R_1}{R}\right)^2=1+(7{\cdot}854)^2=(7{\cdot}86)^2\text{ say},$$

which makes the coil current a little over one-eighth of what it would be were there no self-induction as well. Thus, permitting the core currents increases the strength of the current in the coil about $2\frac{1}{2}$ times. (The magnetisation of the core, on the other hand, is much weakened, except near its boundary. At the boundary it is made $2\frac{1}{2}$ times as strong, but as above mentioned it has only 1/14 part of the boundary value at the centre; whereas, when the core currents are stopped, the value is sensibly the same throughout the core at any moment.)

The retardation ϵ of the coil currents behind the impressed force, which is given by $\tan\epsilon=Ln/R=7{\cdot}854$, or $\epsilon=82°40'$ when the core currents are stopped, is, by equation (54), brought down to

$$\tan\epsilon=7{\cdot}854/11{\cdot}376,\text{ or }\epsilon=35°$$

by letting the core currents flow.

We started with $y=40^2$, and the values of Y_1, etc., corresponding. That is, $4\pi\mu nr^2/\rho=40$. Consequently we may dig out from the same values of Y_1 etc., the results in a variety of other cases, varying the speed and the permeability, resistance and radius of the core in any manner consistent with $y=40^2$.

(TO BE CONTINUED.)

ON PHOTOMETRICAL STANDARDS.

By THOMAS T. P. BRUCE WARREN, Professor of Chemical Technology, Silvertown Institution.

It is probable that for some time to come we shall hear a great deal of the defects of the standard candle as a reference for the comparison of illuminated surfaces, and already several standards have been proposed which undoubtedly offer more reliable means of comparison than can possibly be obtained from candles, however carefully the wicks are prepared or the purity of the stearine secured.

It seems to me that, although a great deal has been written about this matter of standard illuminants, the main points have been overlooked—namely, the portability and simplicity of a standard source of light, and the production of reliably definite multiples of luminosity.

I think few people are prepared to contend that the standard candle fixed by Act of Parliament for the use of gas companies is sufficiently definite for a scientific purpose,

Digitized by Google

although the idea may perhaps be commercially necessary, whatever means may be adopted in order to compare gas lights with the lights given by other methods of illuminating.

The light furnished by a standard candle or lamp giving even an illuminating power of 16 candles is too low for comparison with large electric lights; and while it is quite easy to compare small electric lights, such as the ordinary incandescent lamps, with a gas flame or lamp giving 16 candles, it is very difficult to make the comparison satisfactorily, even if a gas flame of 500 candle-power is to be adjusted against an arc light of 5,000 candles. And yet in many cases such an arc light has been compared with that of a single candle.

This difficulty arises partly, no doubt, from the difference in colour of the two lights. The explanation from the difference in colour does not seem to me quite satisfactory, because we do not experience any difficulty in measuring smaller electric lights against gas flames without the use of coloured glasses.

For comparing electric lights we require a definite standard easily and reliably reproduced, portable and capable of being produced in definite multiples of light power, and which must do away with the uncertainty due to the use of coloured glasses.

From a few experiments made in the laboratory of the Silvertown Institution I feel certain that we may look very hopefully for such a standard in the metal magnesium.

The light emitted by the burning of a piece of magnesium in the form of wire or ribbon can be compared with large electric arc lights without any of the difficulties being met with which surround the use of gas. We may say, too, that the colour of the two lights is very similar.

The intensity of the lights emitted when magnesium wires of different diameters are burnt varies as the weight consumed in a given time, so that by selecting wires of suitable diameter we can easily obtain a light equal to 50 or 5,000 candles without any cumbersome or costly apparatus or difficulty in the experimental operation itself.

I have proposed as the unit of illumination the light given out by a magnesium wire one millimetre diameter burning at the rate of one centimetre per second. This will correspond approximately to the combustion of the unit weight (one gramme) in 500 seconds. From a few roughly-made experiments such a light is equal to 8·25 standard candles.

For greater lights it is safer to use larger wires burning the same weight (one gramme), in that fraction of the above time obtained by dividing by the square of the diameter of the wire, so that the volatilisation of the wire may take place at about the same rate, by which any error due to this cause is avoided. The wire is not so liable to melt and go out, nor does it so easily oxidise as when smaller wires are more quickly burnt.

The advantages in favour of magnesium are that it can easily be obtained in wires of different diameters, and is not so liable to fluctuations as regards purity, &c., as other chemically prepared substances. So long as it is kept from oxidation it can be depended on for giving an uniform light when burnt at the same rate for the same size wire, and within certain limits the quantity of light emitted is directly proportional to the weight consumed in a given time.

So far as my experiments have gone it does not appear as if this means of comparison is accompanied with any of the difficulties due to oil, gas, or candles. A slight objection, which can no doubt be removed by a better form of lamp or holder, by which the wire or ribbon is fed, is that it appears necessary to burn only such lengths at a time that the variations due to the increased rate of combustion from the heated condition of the wire can be avoided.

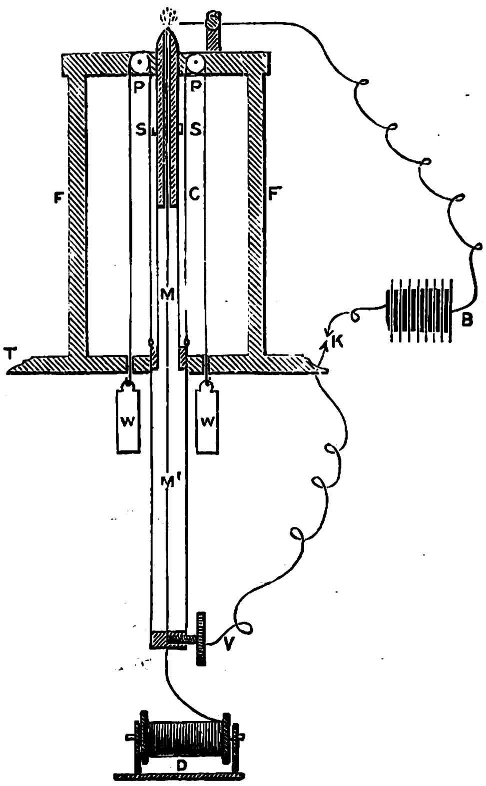
It is obvious that this source as a standard can be used in any photometrical arrangement, such as that of Bunsen or Rumford, and under conditions in which neither of these could be applied.

On a future occasion I hope to give the actual illuminating power due to the combustion of wires of different diameters and burning at different rates.

The simplest arrangement for fitting up a holder for the magnesium wire is to clamp a piece of a clay tobacco pipe stem in an ordinary burette clamp, and to feed up the wire by hand at the required rate. An automatic system to replace the latter renders the arrangement complete. The wire may be lighted by a match or by a spark from a battery or induction coil. The wire projecting from the top of the pipe is bent over so as to make contact with a platinum tipped wire from the battery, the other wire from the battery being led to a key, which enables the operator to ignite the wire and to start the photometer clock at the same instant. The feed gear can be made to stop the clock as soon as the measured quantity of wire is burnt.

A convenient table could be drawn up showing the candle-power given out by different-sized wires burning at a fixed rate, say one metre per minute, when a greater or lesser rate of consumption could be corrected to the required rate, as in ordinary photometrical calculations for gas, oil, or candles.

The following simple contrivance admits of giving greater accuracy to the experimental determinations of the time integral:—F is a frame made of wood supported on the table T. M is a brass tube carrying at its upper end a clay tube, C. The length of M and C together may be about 4ft. M′ is a slightly wider tube sliding with slight friction so as to enclose



M and C as far as the stops S S. The lower end of M′ is closed with a metal plug having a hole just large enough to admit the wire freely, which is then secured by a screw, V. To the upper end of the tube M′ are attached two cords passing over the pulleys P P fixed to the frame F, and carrying two weights W W, which in their descent draw M′ upwards, and with it the wire. The weights are adjusted so as to draw the tube up as fast as the wire is burnt. The stops are formed best of a rubber ring or washer, which can be moved along the tube M or C so as to arrest the upward motion of M as soon as the required length of the wire is burnt. D is a bobbin of wire from which the supply is drawn. A contact key is inserted at K. B is a battery for lighting the wire.

In all photometrical apparatus the parts necessary for the determination of the initial candle-power are always very costly, and I have no doubt that this fact has acted as a serious barrier in accurate electric light measurements. These considerations are removed by the new standard now proposed. An accurate measure of length can easily be made, so that having once fixed on the candle-power of a given-sized magnesium wire when burning, it will only be necessary to apply numerical corrections for the rate of burning.

At a meeting of the Society of Telegraph Engineers and Electricians on December 13th, 1883, I put forward in the course of the discussion, and in a general form, the grounds for dissenting from the views generally held, or at least expressed, as to the applicability of Sir Wm. Thomson's law of economy in conductors to cases to which that philosopher would certainly never have applied it. Neither time nor the power of memory allowed me to do more than treat the subject most generally; but the importance as regards the outlay of money and loss of energy can only be thoroughly appreciated by giving values to symbols and going practically into the results. This I propose doing in the present communication

The dogmatic forms given to the law of economy are the two following:—

1. The area of cross-section of the conductor is proportional to the current it has to carry.

2. The interest on the whole outlay in installing the conductor is equal to the value of the energy absorbed.

These two forms are different ways of expressing the same idea, and the one is true or untrue in the cases when the other is true or untrue, as will be shown.

Let C be the current required to be carried by.

„ r = the resistance of 100 yards of conductor, of cross-section 1 square inch.

„ y = the cost of one horse-power electric maintained for one year.

„ t = the proportion of entire time employed.

„ x = rate of interest on money laid out in installing the conductor, together with sinking fund required annually to maintain the installation in working order, per centum of the original cost.

„ A = the area of cross-section of conductor in square inches.

Further, let the whole expense of the conductor and its installation be dependent on its cross-sectional area in a way represented by a series of terms involving any powers of that area, not omitting the zero power which will occur in a constant term, as follows:—

$$a + bA + cA^m + dA^n + \text{etc.}$$

Here a is a constant term; bA is a term varying as the cross-section of conductor; $c\,A^m$, $d\,A^n$, etc., are any other terms involving any other powers of A.

The value of the interest and depreciation on this sum is equal to

$$\frac{x}{100}\left\{a + bA + cA^m + dA^n \text{ etc.}\right\}$$

The power expended is $\frac{C^2 r}{A}$ in watts. But one watt costs $\frac{y}{746}$ when maintained for a year; therefore the power employed would cost $\frac{C^2 r}{A} \cdot \frac{y}{746}$, if employed during the whole year. But when the fraction of the year the current flows is only t, the cost per annum will be $\frac{C^2 r}{A} \cdot \frac{y}{746} \cdot t$. Therefore the total cost in energy absorbed and conductor installed and maintained per annum is

$$\frac{C^2 ryt}{A\,746} + \frac{x}{100}\left\{a + bA + cA^m + dA^n \;\ldots\right\}$$

Now this form generally admits of a minimum, found by differentiating it with regard to A, and equating the result to zero. Thus

$$-\frac{C^2 ryt}{A^2\,746} + \frac{x}{100}\left\{b + cmA^{m-1} + dnA^{n-1} + \ldots\right\} = o.$$

Multiplying through by the quantity A, and transfering terms,

$$\frac{C^2 ryt}{A\,746} = \frac{x}{100}\left\{bA + cmA^m + dnA^n + \ldots\right\} \quad \ldots \quad \alpha$$

$$= \frac{x}{100}\left\{a + bA + cA^m + dA^n + \ldots\right\}$$

$$+ \frac{x}{100}\left\{-a + \overline{m-1}\,cA^m + \overline{n-1}\,dA^n + \ldots\right\} \ldots \beta$$

The term on the left is equal to the cost of the energy absorbed, and the first series on the right is the annual cost of installing and maintaining the conductor, and these two cannot be equal to one another except when the second series on the right is equal to zero.

This occurs when $a = 0$, $m = 1$, $n = 1$, &c., *i.e.*, when there is no absolute term as a, and no power of A involved in the con-

* Paper read at the Society of Telegraph Engineers and of Electricians, after Prof. Forbes' paper.

Digitized by Google

ductor but the first power; and when this is the case the equation a shows that C^2 varies with A^2, for then $\frac{C^2}{A^2}$ is constant, or $\frac{C}{A}$ is constant, and the area is proportional to the current it has to carry. But when the first power is involved alone in the expense of the conductor, the meaning is that the cost is proportional to the area. Now I propose to show, first, that in an insulated conductor in the form of a cable, the expense of the conductor is not proportional to the area of the cross section; and, secondly, to show that the price of the cable can be formulated very closely in terms of the cross section. And obviously, if we can do this satisfactorily, we have no difficulty in finding at once the economical current for a section by the foregoing rules.

To carry out these points I beg to draw attention to the Table A on page 106, compiled from the price list of Messrs. Siemens Brothers, of Charlton.

Each horizontal line refers to the same conductor, and the first column gives the number of yards making up the tenth of an ohm. These numbers are used as denominations for the particular conductors, and are of course assuming the wires are always of the same conductivity, proportional to the cross-section of the conductor.

The second column gives the number of wires in each conductor.

The third gives the area of cross-section in square inches, called A.

The fourth gives the vertical diameter, called d, deduced from the equation $d = \sqrt{\frac{4A}{\pi}}$.

The fifth column gives the price of the bare conductor from the price list. It is marked a. The price is in pounds sterling per 100 yards run.

The next gives the result of applying a linear equation in A, viz., 91·783 A most nearly giving the actual price.

Then follow five series of four columns each.

Each series corresponds to a specification of the covering of the conductor, as follows:—

- *b.* Insulated with india rubber and tape.
- *c.* Insulated with india rubber, jute, and tape.
- *d.* Insulated with gutta percha.
- *e.* Insulated with gutta percha, jute, and tape.
- *f.* Insulated with gutta percha, jute, and tape, and iron sheathed.

The first column of each series gives the price from the price list of the covered conductor in pounds sterling per 100 yards run.

The second column gives the difference between the preceding column and the price of the bare conductor, that is to say the price of the insulation.

The third column gives the price of this as deduced from the formula found to give the real prices most approximately.

The fourth column gives the results of the formula of insulation combined with that of the bare conductor.

I have attempted only to find linear equations in d and A to express these prices. Greater approximation could be obtained by more complex formulæ, but even with those I have employed an inspection will show very rarely, I think, a deviation of as much as five per cent. But even this is not to be found in the cases where the total sum is considered.

Now, whether we look at the formula or at the figures taken from the price list, it is clear that the cost of insulation largely deviates from proportionality to the cross-section of the conductors. Consider, for instance, the 1st and 5th row of the column marked $c - a$, the figures being 3·5 and 8 respectively. The conductors are in cross-section as 1 to 8·8, and if the insulation expense were assumed to be proportional to the conductors, taking the 3·5 as the basis, we ought to find the expense of the insulation of No. 880 in this case 3·5 × 8·8, or 30·8 pounds instead of only 8 pounds, which it is. Similarly with all the other insulation prices. Moreover, these insulation prices are not small compared with those of the conductors bare. In many cases they are greatly in excess. According to specification f, it costs six pounds to insulate a conductor costing only £2 10s.

If we accept the formula as a representation of the price of a cable, it is easy in any particular specification to give the value of the economical current for any required cross-section, and by constructing a curve of values to perform the opposite problem, *i.e.*, to find the proper cross-section for a given current, the other necessary data being of course also given. Or a table may be easily calculated, as in the following cases.

As an example, the following table gives the values of the currents corresponding to certain areas of cross-section under the following data. The specification is that corresponding to e—insulation of gutta percha, jute, and tape.

The conductivity of the copper is $\frac{95}{100}$ of copper, giving 1 ohm in 25 miles of 1″ section.

The time of working is 8 in the 24, or $t = \frac{1}{3}$.

The cost of an electrical horse-power maintained for a year is £10.

The rate of interest and depreciation together is 7·5 per cent.

Area in square inches.	Economical current in amperes.	Economical intensity or current ÷ area.
·01	11	1103
·04	40	999
·09	86·5	961
·16	150·7	942
·25	232	930
·36	332	922
·49	448·8	916
1·00	906	906

If the working hours were 12 in 24, instead of 8 in 24, the numbers in the second and third columns of the table would have to be reduced in the proportion of $\sqrt{3} : \sqrt{2}$, *i.e.*, multiplied by the fraction ·816.

The formula corresponding to the above case is

$$\frac{C^2}{A^2} = 44259{\cdot}2 \left\{ \frac{1}{\sqrt{A}} + 17{\cdot}545 \right\}$$

The following table relates to specification b, but otherwise the same data are used:—

Area in square inches.	Current in amperes.	Intensity or current ÷ area.
·01	10·5	1046
·04	37·28	932
·09	80·19	891
·16	139·2	870
·25	214·25	857
·36	305·28	848
·49	412·58	842
1·00	830	830

The formula is

$$\frac{C^2}{A^2} = 45126{\cdot}1 \left\{ \frac{1}{\sqrt{A}} + 14{\cdot}27 \right\}$$

Similarly tables and curves can be formed whenever it is possible to formulate the price of the cable.

It is hoped that these cases have sufficiently indicated the method to be followed generally.

Here it may be well to reflect what a great advantage it would be for the general purposes of design if manufacturers were to make a practice of supplying prices in a formulated shape. It is presumed that they all have their modes of calculation, and it seems easy to throw the expression of their results into an algebraical form.

The above results have been deduced from a single price list, and it may be the prices are somewhat high. No allowance, too, has been made for discount, which would have the effect of diminishing the intensity of the economical current in half the ratio of the discount. But enough has perhaps been said to show the fallacy of the ordinary modes of quoting the economical law of Sir William Thomson, and assigning a fixed value to the current density.

ELECTRIC CURRENTS AND THE HUMAN BODY.

Dr. Stone's letter, which will be found in another column, asking for particulars of facts relating to the effects of electrical currents on the human body will, we have no doubt, revive the interest which that gentleman was the first to arouse in a subject of no small importance to electrical research. The paper read by Drs. W. H. Stone and W. J. Kilner before the Society of Telegraph Engineers in March, 1882, a report of which will be found in our issue of the 18th of that month, gave an account of what were, we believe, the first serious attempts made in this country to investigate the subject of electrical therapeutics. Ever since that time Dr. Stone has been devoting attention to this matter, and he will probably give the world the benefit of his subsequent experience in a paper shortly to be read at the International Health Exhibition. There is one class of phenomena, however, beyond the domain of the experimenter, namely, the effect on the human body of electrical currents fatal or dangerous to life. Dr. Stone therefore asks for information as to the observed facts where accident has furnished what experiment may not seek. From the time of the famous Russian philosopher who gained a place among the martyrs of science by losing his life while attracting electricity from the clouds, down to the present era of electric lighting and electrical transmission of power there have been a vast number of casualties, the unavoidable consequences of dealing with a force the effects of which were only imperfectly understood. More especially has this been the case since the introduction of electric lighting, the diminution of such accidents, however, of late showing that the chief danger arose from our ignorance of its character. How extremely ignorant we still are on this point is shown in the circumstance that whenever anybody is killed or maimed by electrical shock there is always somebody else ready to declare that he has submitted himself to precisely similar conditions without feeling any ill effects. The proprietors of powerful dynamos almost ask us to believe that electrical currents are only dangerous to persons of inferior education, and that when a man has undergone a course of scientific training the powers of death are mollified in compliment to his superiority. Dr. Stone of course does not believe this, and he asks for the truth with regard to all accidents of the kind, whether fatal or only serious, due to the passage of electrical currents through the human body. The chief facts required by him are, as to the strength of the current, whether constant or alternating, and the interval that elapsed, if any, between the shock and the death of the victim.

This is what Dr. Stone asks for, and we invite our readers engaged in the business of applied electricity to furnish him with all the information in their power. Although not explicitly referred to by Dr. Stone, cases of death by lightning, when the facts are well authenticated, would no doubt be of service to him—that is to say, the physical effects observed in cases of fatal accident through stroke of lightning. It would be too much to expect that any particulars as to the temperament and constitution of the victim can be given; but these, we presume, are by no means unimportant data, and in future observations it may be hoped they will be noted. We speak under correction of a medical authority like Dr. Stone, but we imagine that suddenness, or rather unexpectedness, constitutes one chief element of danger from electric shock. There are of course currents of electricity that not only extinguish vitality, but would wreck the body were it twenty times stronger than it really is; but there are others which, we fancy, cause death simply by blow to the nervous system. We have all experienced shocks which have distressed us considerably, and many people have voluntarily submitted to what, if they had received it unawares, might have killed them. It is here that the element of temperament comes in, and it is probable that a good many deaths attributed to the effects of electrical current are really due to something closely akin to the effect of fright.

Making allowance for these cases, however, there are no doubt many in which the bodily effect of the current has left traces sufficient to mark the true cause of death, and it is these which would prove most helpful to the investigation Dr. Stone has in hand. At the meeting of the Society of Telegraph Engineers already referred to, Dr. Stone, although ridiculing the pretensions of the vendors of electrical appliances for curative purposes, acknowledged that some useful results—or at all events encouraging results—had been obtained by the application of currents of electricity in certain cases of disease. The members who attend the forthcoming gathering of the Society at the Health Exhibition will be curious to learn whether these encouraging results have been borne out by further tests at the hospital with which Dr. Stone is connected. In the discussion which took place two years ago several points, as we remarked at the time, were either overlooked or misunderstood. Amongst these we may mention

Digitized by Google

the unexplained fact of a current passing by the arms through the body being felt only at the places of contact with the conductors. With increase of strength the shock, or rather shocks, are felt farther away from the terminals, and when still stronger current is used—approaching to the dangerous point—the two sensations, for there are two, are felt near each other on either side of the chest. This is contrary to our practical experience of the equable flow of current through an ordinary conductor, and it would seem that either the human body differs from every other known form of galvanometer—if we may so call it—or else that the ordinary galvanometer fails to tell us something that really happens during the passage of currents through high resistances. The question arises, is sensation a true indicator of the reach of the efficient current? If so, then for therapeutic purposes the terminals must be placed close to the seat of disease, or the currents must be of increased strength. These are trifles, however, compared with the one essential question—What is the actual physical effect of the current apart from the sensation it occasions? At present it is like a medicine whose only known virtue is its nastiness.

CORRESPONDENCE.

ACCIDENTS FROM ELECTRICAL CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Would you kindly ask your readers to furnish me with information as to fatal or serious accidents from the passage of electrical currents through the human body? I write for this with a view to my proposed paper on behalf of the Society of Telegraph Engineers and Electricians at the Health Exhibition. The chief points to be noted are the strength and nature of the current, whether constant or alternating, and the rapidity of death. At least three modes of fatal injury seem possible under the conditions present, and it is important to discriminate between them. It would be convenient to send any replies to this address, viz., Society of Telegraph Engineers and Electricians, 4, The Sanctuary, S.W.—Yours, &c., W. H. STONE.

[We have called attention to Dr. Stone's request in our leading article.—ED. *E.*]

A NEW FORM OF SPRING FOR ELECTRIC AND OTHER MEASURING INSTRUMENTS.*

BY PROFESSORS W. E. AYRTON, F.R.S., AND JOHN PERRY, M.E.

(CONCLUDED FROM PAGE 89.)

Springs with a Rectangular Section.—For practical purposes it is obviously more convenient to use in the construction of our springs thin strips of a rectangular section rather than of an elliptic section. We have therefore now to consider how equations 13, 14, and 15 will be modified if our strip has a rectangular section, the longer side of the section being $2a$ and the shorter side $2b$. In this case

$$B = \tfrac{4}{3}ab^3E,$$

and since, as was discovered by M. Cauchy in 1829, the torsion rigidity of a rectangle bears to the torsional rigidity of an inscribed ellipse the proportion of their moments of inertia about a line drawn through the common centre perpendicular to their plane, in the case when one principal dimension is several times the other, it follows that

$$A = N\pi\frac{a^3b^3}{a^2+b^2} \times \frac{\frac{4}{3}ab^3}{\frac{\pi}{4}ab^3},$$

or

$$A = \tfrac{16}{3}N\frac{a^3b^3}{a^2+b^2}.$$

* Reprinted from the *Proceedings* of the Royal Society.

Hence

$$\phi = \frac{lFr\sin\alpha\cos\alpha}{4ab^3}\left(\frac{3}{4N}\frac{a^2+b^2}{a^2} - \frac{3}{E}\right),$$

$$d = \frac{lFr^2}{4ab^3}\left(\frac{3}{4N}\frac{a^2+b^2}{a^2}\cos^2\alpha + \frac{3}{E}\sin^2\alpha\right);$$

or, as b^2 is insignificant in comparison with a^2,

$$\phi = \frac{3lFr\sin\alpha\cos\alpha}{4ab^3}\left(\frac{1}{4N} - \frac{1}{E}\right) \quad . \; . \; . \; . \; . \; . \quad (16),$$

$$d = \frac{3lFr^2}{4ab^3}\left(\frac{\cos^2\alpha}{4N} + \frac{\sin^2\alpha}{E}\right) \quad . \; . \; . \; . \; . \; . \; . \quad (17).$$

We will now calculate the value of f, the maximum stress at any point in the rectangular section.

The shear stress at any point xy in such a section of the prism which has received a twist τ per unit of length is, where the axes of x and y are parallel to the edges of the section, and the origin the centre of the section, z being at right angles to the section,

$$N\left(\tau x + \frac{d\gamma}{dy}\right) \text{ in the directions of } y \text{ and } z,$$

and

$$N\left(-\tau y + \frac{d\gamma}{dx}\right) \text{ in the directions of } z \text{ and } x,$$

where γ equals $-\tau xy +$ an expression which vanishes if the thickness of the strip is very small.

Hence, since

$$\frac{d\gamma}{dy} = -\tau x,$$

and

$$\frac{d\gamma}{dx} = -\tau y,$$

it follows that the shear stress at a point xy is

0 in the direction of y,

and $-2N\tau y$ in direction of x,

so that the whole shear stress at a point is $-2N\tau y$, and the shear stress, q, at the middle of the longer edge of the rectangular section, where we may suppose the shear stress is the greatest, is $2N\tau b$.

Now if C is the twisting couple, we know that

$$\tau = \frac{C}{A},$$

hence

$$\tau = \frac{3Fr\cos\alpha}{16Na^3b^3}(a^2+b^2),$$

and

$$q = \frac{3Fr\cos\alpha}{8a^3b^2}(a^2+b^2).$$

Also, since $Fr\sin\alpha$ is the bending couple, the greatest stress due to bending,

$$p = \tfrac{3}{4}\frac{Fr\sin\alpha}{ab^2}.$$

Hence if f is the greatest total stress anywhere in a section, it may be shown that

$$f = \tfrac{3}{8}\frac{Fr}{ab^2}\left\{\sin\alpha + \sqrt{1 + \frac{b^2}{a^2}\cos^2\alpha\left(\frac{b^2}{a^2}+2\right)}\right\}.$$

Or, as a is very large in comparison with b,

$$f = \tfrac{3}{8}\frac{Fr}{ab^2}(1+\sin\alpha) \quad . \; . \; . \quad (18).$$

If, as is usual in the case of the springs we employ, the edges of the strip nearly touch one another in two consecutive coils, and the angle of the spiral is 45°, we have the area of the cylinder which the metal strip approximately covers, or $\frac{2\pi rl}{\sqrt{2}}$ equal to the area of the strip, or $2la$, so that

$$\frac{r}{a} = \frac{\sqrt{2}}{\pi},$$

and equations (16), (17), and (18) may be simplified thus

$$\phi \propto 0{\cdot}17\,\frac{lF}{b^3}\left(\frac{1}{4N}-\frac{1}{E}\right) \qquad (19).$$

$$d \propto 0{\cdot}17\,\frac{lFr}{b^3}\left(\frac{1}{4N}+\frac{1}{E}\right) \qquad (20).$$

$$f \propto 0{\cdot}29\,\frac{F}{b^2} \qquad (21).$$

Use of Spring to determine $\frac{E}{N}$.—Before proceeding to a description of the various measuring instruments in which we have applied this new form of spring, we may mention one interesting application of it to enable us to determine readily the ratio of the modulus of rigidity, N, to Young's modulus of elasticity, E, for any material. It is well known that the celebrated conclusion of MM. Navier and Poisson from Boscovich's molecular theory requires that the ratio of E to N should be

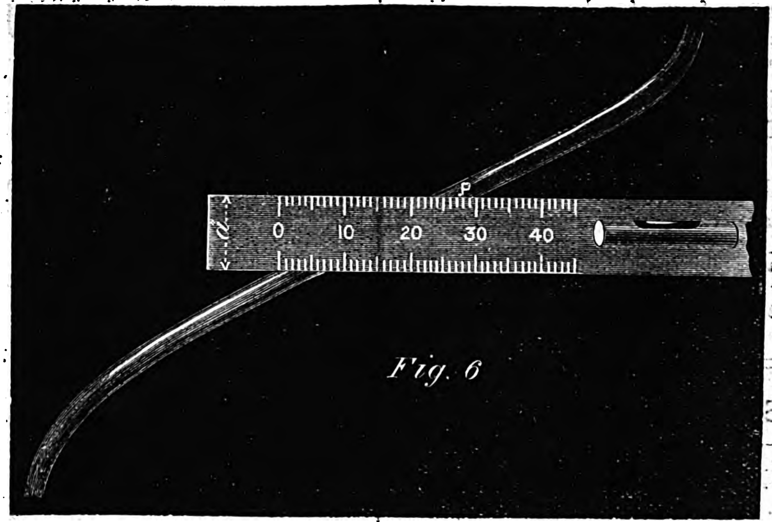

Fig. 6

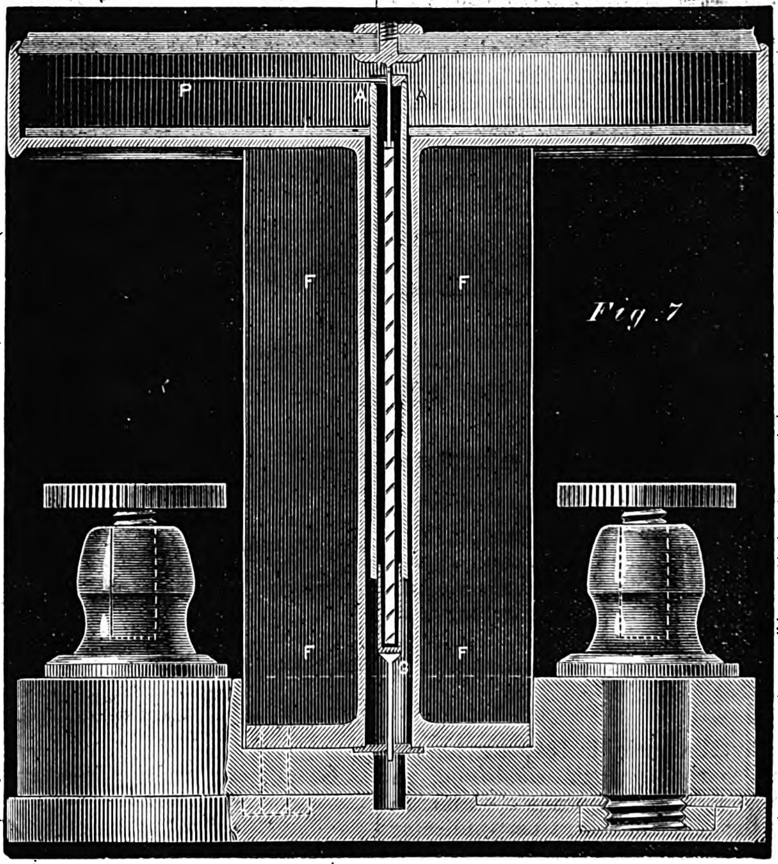

Fig. 7

We have preferred to say that ϕ, d, and f are respectively proportional rather than equal to the expressions on the right hand side, because when the strip is wide in comparison with the radius of the cylinder about which it is bent, the strip receives in addition to the bending and shear strains which we have considered a lateral bending also, and the exact effect of this we have not yet fully investigated.

2·5 for all solids. Professor Stokes showed that this conclusion was impossible if its authors supposed it to apply to jellies and to india rubber, and that it was probably untrue in the case of metals; and Wertheim, Kirchhoff, Thomson, Everett, and others have experimentally shown its untruth in the case of brass, iron, copper, and glass. In pursuance of the present investigation it has struck us that this ratio may be most con-

Digitized by Google

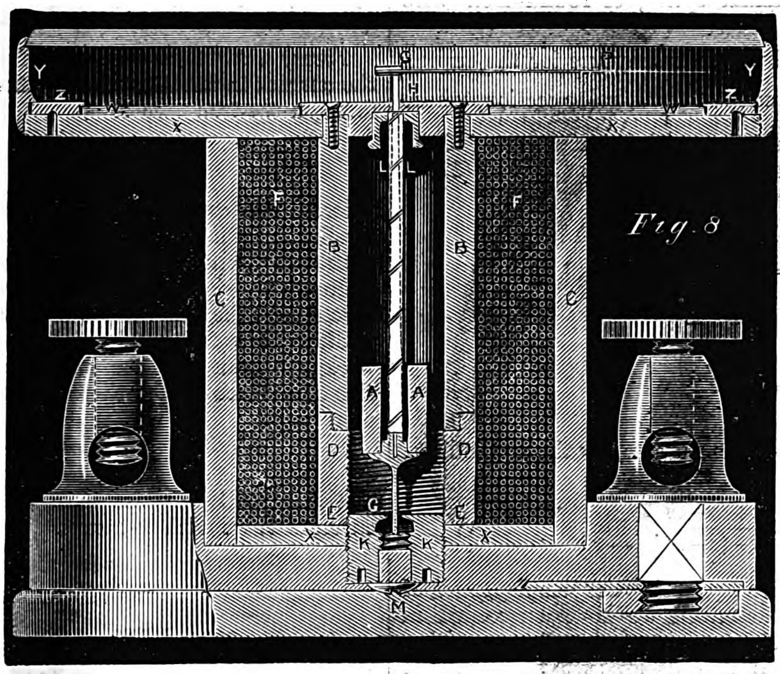
veniently determined by the use of our springs from one experiment.

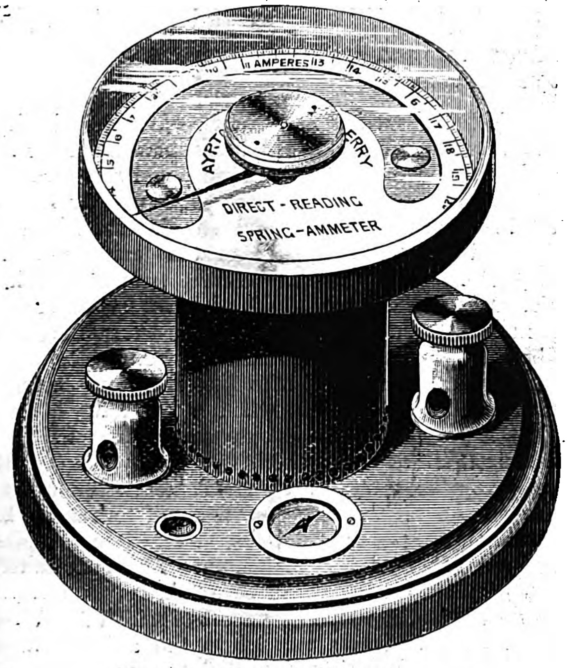
When the spring is made of round wire, so that a and b are equal to one another, we have from equation (11)

$$\frac{r\phi}{d} = \tan a \frac{\frac{E}{N} - 2}{\frac{E}{N} + 2 \tan^2 a};$$

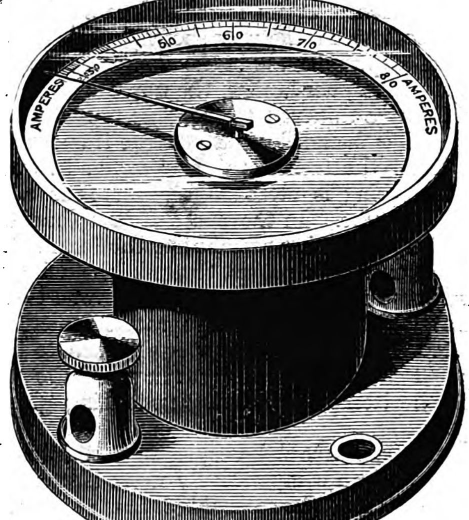
wire is observed in its position in the upper scale, the reading being b. Now the spring is elongated by an axial force until the point P comes opposite a point on the lower scale, and the reading is now c. As the two scales are similar and parallel to one another, and as a spirit-level has been employed to make the scales horizontal, it is obvious that as the axis is vertical

$$\frac{a}{c-b} = \frac{d}{r\phi} = \tan \beta,$$





Direct Reading Spring Ammeter.



Shielded Instrument.

let $\frac{r\phi}{d}$ be called cot β, then it can be shown that

$$\frac{E}{N} = -2 \tan a \tan (a + \beta),$$

so that if a is 45°

$$\frac{E}{N} = \frac{\tan \beta + 1}{\tan \beta - 1} \quad \text{. . . . . . (22).}$$

In order to measure tan β most conveniently, we may employ (Fig. 6) a pair of cylindric scales, the distance apart of which, close to the wire of the spring is a inches. A point, P, on the

so that

$$\frac{E}{N} = 2\frac{a + (c-b)}{a - (c-b)}.$$

We have used three springs made from round wire respectively of brass, iron, and steel for the sake of illustration. In all of them we find that $c - b$ is small in comparison with a, so that roughly we may say that the excess of $\frac{E}{N}$ over 2 is $\frac{(4c-b)}{a}$, that is, is proportional to $(c - b)$. The cylindrical scale has only been introduced for the sake of illus-

Digitized by Google

tration. For an accurate determination of $\frac{E}{N}$ a telescope would be employed having a motion about the axis of the spring, and also a motion parallel to the axis, and by means of which the motion of a point on centre line of the wire when an axial force is employed would be accurately observed. It is sufficient to say that the brass spring of round wire exhibited to the Society gives a value of $\frac{E}{N}$, which is 8 per cent. less than the value given by the similar spring of round iron wire exhibited.

Instead of using a round wire, we may use for the experimental determination of $\frac{E}{N}$ a strip of rectangular section, whose breadth is very great in comparison with its thickness. If the angle of the spiral is 45°, then from equations (16) and (17) it follows that

$$\frac{\phi r}{d} = \frac{\frac{1}{4N} - \frac{1}{E}}{\frac{1}{4N} + \frac{1}{E}},$$

$$\frac{E}{N} = 4\frac{d + \phi r}{d - \phi r};$$

therefore measuring ϕr as $c - b$, and d as a, by the method just described, we have

$$\frac{E}{N} = 4\frac{a + (c - b)}{a - (c - b)}.$$

Some Practical Uses of the Springs.—By the employment of springs such as we have described we have succeeded in making *ammeters* and *voltmeters*, or instruments for measuring respectively electric currents and differences of potential, in which the pointer moves over in some cases as much as 270° of the scale instead of only 50°, which is all that can be obtained with ordinary galvanometers. One form of the instrument is shown in Fig. 7, where AA is a thin hollow tube of charcoal iron attached at its lower end to a brass piece, G, guided at the bottom in the way shown. To G is attached the lower end of a spring made in the way we have described of silver or hard phosphor-bronze, the upper end of which is attached rigidly by a thin rod to the glass top of the instrument, which itself is fastened rigidly to the framework of the instrument. The rod attached to the glass, and to which the upper end of the spring is attached, also serves as a guide to the top of the iron tube. In the space FF a solenoid wire or strip is wound, its ends being attached to the terminals shown. Hence, when a current is passed through the wire, the iron tube is sucked into the solenoid, and its lower end G, to which the spring is attached, receives a large rotatory motion, which is communicated directly to the pointer attached to the top of the iron tube. Parallax in taking readings of the pointer is avoided by the horizontal scale being on looking glass in the well-known way.

By making the iron tube AA very thin, so that it is magnetically saturated for a comparatively weak current, by fixing it so that it projects into the solenoid a fixed distance which has been carefully determined by experiment, and by constructing the spring in conformity with the conditions worked out in this paper, so as to obtain a large rotation with minimum stress, and with not too much axial motion of the free end of the spring, we have succeeded in obtaining deflections up to 270° directly proportional to the current, and without any permanent set being given to the spring.

To prevent a spring taking a permanent set for a large deflection, it is of great importance that the spring after being delivered by the maker should receive a large degree of permanent set in the direction in which we wish it to be afterwards strained in ordinary working.

In spite of the fact that Professor J. Thomson in the *Cambridge and Dublin Math. Jour.*, November, 1848, explained the importance of initial strains in materials, the reason is not yet sufficiently well understood why when a round bar has been well twisted beyond the limit of permanent set in a certain direction it has twice as much elastic strength to resist torsion in this direction as in the opposite direction. Now in the very act of manufacturing our springs, that is in the bending of the strip, the material acquires strains which are just opposite in character to the initial strains which we wish it to possess, for, as already explained, if the spring be constructed as in Fig. 3, an extension of the spring produces a rotation tending to uncoil it. Hence a spring must not be regarded as ready for use until it receives a good set by means of a weight hung from its end.

Theory of the Solenoid Spring Ammeter or Voltmeter.—If C is the current in amperes flowing through the coil, the attractive force on the iron core is

$$\frac{KC^2}{1 + SC},$$

where S is a constant, which is the greater as the current is smaller for which the iron tube AA, Fig. 7, becomes saturated with magnetism. The position of this iron core in the solenoid is so selected that K remains practically constant throughout the small range of downward motion of the core.

Since the rotation ϕ has been produced by an axial force, we know, from the theory of the spring already given, that this axial force is $p\phi$, where p is some constant. Hence

$$p\phi = \frac{KC^2}{1 + SC},$$

and since SC is great in comparison with unity for such currents as we wish to measure, we have

$$\frac{p\phi}{K} = \frac{C}{S} - \frac{1}{S^2},$$

or

$$C = \frac{Sp}{K}\phi + \frac{1}{S},$$

that is, equal divisions of the scale correspond with equal additions to the strength of the current except close to the zero, and we usually do not graduate these instruments within 5° of the zero.

Shielded Measuring Instruments.—When it is desired to use the instrument close to a dynamo machine or electro-motor in action, we have adopted a different and somewhat special form of construction, which is shown in Fig. 8, by means of which the instrument is to a great extent shielded from even powerful external magnetic fields. In this instrument the electro-magnet consists of a hollow core, part of which, BB, is of charcoal iron, and part, DE, of brass or other non-magnetic metal. The outside tube, CC, and the plates, XX, top and bottom, are also of charcoal iron. The space FF is filled with insulated wire in electrical connection with the terminal, so that when a current is sent through the instrument an intense magnetic field is formed between D and E, which are the poles of the electro-magnet. To the iron tube AA, also made of charcoal iron, the spiral spring, in this case made of extremely hard steel, is attached, the other end being attached to the piece F, which is fixed relatively to the bobbin. The spindle GG, which is fixed to the moving iron core AA, moves freely in bearings HH, so that the only movements of which A is capable are one of rotation and one parallel to the axis of the bobbin. As the iron core A projects into the strong magnetic field between D and E it is strongly attracted towards E when the current flows, and, as before, causes a large rotation of the pointer P over the scale. As a means of varying the power of the instrument an adjustable iron piece K is provided, which can be screwed nearer to or farther from the core A, and by the use of which the sensibility of the instrument can be adjusted so as to make the instrument "direct reading," that is to say, each division of the scale can be made to correspond with 1 ampere of current, or ·1 volt difference of potential, and the employment of a constant such as 1·34 ampere, or volt, per degree, which has hitherto been necessary with our measuring instruments, is now avoided. This power of adjustment produced by the use of the movable iron piece K, combined with the

Digitized by Google

ease with which more or less wire can be wound on to the instrument, which also constitutes a second adjustment of sensibility, is of considerable importance, since the employment of a constant has not only led to error and delay in measurements made in electric light factories, but has caused the breakage of the pointer or the destruction of an instrument from a far too powerful current being sent through it by an observer (often a man with little experience in the employment of instruments) having confounded the constant of some other instrument with that of the one he was using.

The steel strip used in the construction of the spring for these shielded instruments is 0·0017 inch thick, and in a book just published on "Steel and Iron," by Mr. Greenwood, he mentions that some specimens of remarkably thin steel, $\frac{1}{110}$ of an inch, were shown in the Paris Exhibition, so that steel we are using is nearly as thin as that referred to by Mr. Greenwood. But within the last few days we have received from Mr. Charles Jowitt, of Sheffield, a specimen of steel rolled for us only just over 0·001in. in thickness, which is perhaps the thinnest steel yet made.

We have to thank one of our assistants, Mr. Bower, for so earnestly carrying out a long series of experiments on these very delicate springs.

Weighing Machines.—Another class of instruments in which we have practically employed this spring are weighing machines, and Fig. 9 shows one of the arrangements we adopt. The scale pan is prevented from turning by the part A B being square and fitting very loosely a square hole in C. This arrangement introduces practically no friction, and prevents the moment of inertia of the scale-pan and load interfering, by means of a rotatory motion, with the rapidity with which the pointer comes to rest when a load is put into the pan. The position of the pointer P, which revolves when a weight is placed in the scale-pan, is read off upon the spiral scale, D, which, in this specimen, we have graduated in pounds. In another of these weighing machines, shown in Fig. 10, the

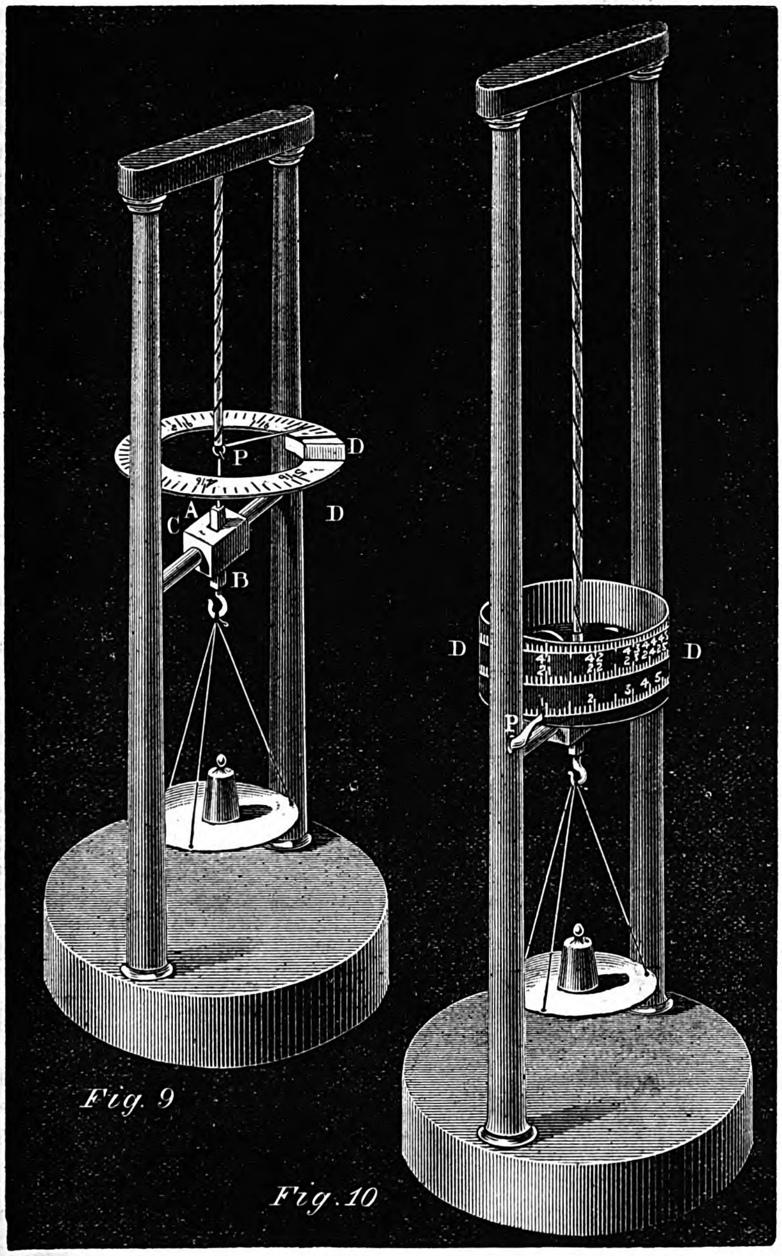


Fig. 9

Fig. 10

arrangement is the same with the exception that a cylindric scale, D, is fixed to the end of the spring and turns with it; the pointer P fixed on the frame of the instrument points to an indication of the weight on a spiral line drawn on the cylinder D. This second arrangement allows us to employ springs whose ends have a relative motion of five or six revolutions.

We have also made certain weighing machines where the weight is placed on a pan resting on the top of a rod passing up through the spring, and attached to the bottom of the spring, but hitherto we have found that this arrangement introduces too much friction.

When a very long spring is required for any purpose, and

where the weight of the spring itself would cause greater stresses on the upper part than on the lower part of the spring, it is our custom to let the breadth and thickness of the strip of material remain unaltered, but to let the diameter of the coils diminish towards the upper parts. The formulæ already given suffice to show how this may be done so as to obtain uniformity of maximum stress at all sections.

We also present before the Society a model showing a combination of bifilar and spiral spring suspension, in which great rotation and small axial lengthening or shortening are produced by an axial force.

THUNDERSTORMS.

BY PROFESSOR TAIT, F.R.S.

[At the commencement of this year Professor Tait delivered two lectures on the above subject at the Philosophical Institution, Edinburgh. The basis of these lectures is found in the lectures delivered at Glasgow in 1880, which Professor Tait has kindly annotated and permits us to use.—ED. *E.*]

A few years ago no qualified physicist would have ventured an opinion as to the nature of electricity. Magnetism had been (to a certain extent, at least) cleared up by an assumption that it depended on electric currents; and from Œrsted and Ampère to Faraday and Thomson, a host of brilliant experimenters and mathematicians had grouped together in mutual interdependence the various branches of electro-dynamics. But still the fundamental question remained unsolved, *What is Electricity?* I remember Sir W. Thomson, 18 years ago, saying to me, "Tell me what electricity is, and I'll tell you everything else." Well, strange as it may appear to you, I may now call upon him to fulfil his promise. And for good reason, as you shall see.

Science and Scotland have lately lost in Clerk-Maxwell one of their greatest sons. He was, however, much better known to science than to Scotland. In scientific ranks true merit is almost always certain to be recognised—in popular ranks modest merit scarcely ever is. His was both true and exceptionally modest merit. One grand object which he kept before him through his whole scientific life was to reduce electric and magnetic phenomena to mere stresses and motions of the ethereal jelly. And there can be little doubt that he has securely laid the foundation of an electric theory—like the undulatory theory of light admirably simple in its fundamental assumptions, but, like it, requiring for its full development the utmost resources of mathematical analysis. It cannot but seem strange to the majority of you to be told that we know probably as much about the secret mechanism of electricity as we do about that of light, and that it is more than exceedingly probable that a ray of light is propagated by electric and electro-magnetic disturbances. It can be but a small minority of you who have been at college so recently as to have been taught this. Yet, from the purely scientific point of view, it is one of the most remarkable advances made during this century.

But to know what electricity is, in the same sense as we may be said to know what light is, does not necessarily guide us in the least degree to a notion of its source in any particular instance. What, for example, causes the luminosity of fireflies, glowworms, &c., among natural objects, and of phosphorescent watch-dials among artificial ones? The answer is not yet ready, though it may soon come. So we might know quite well *what* is electricity and yet be, as I told you at starting *we are*, almost entirely uncertain of the exact source of *atmospheric* electricity.

To come to my special subject. I am not going to try to describe a thunderstorm. First, because I am certain that I could not do it without running the risk of overdoing it, and thus become sensational instead of scientific; and secondly, because the phenomenon must be quite familiar, except perhaps in some of its more singular details, to every one of you.

Science has to deal with magnitudes which are very much larger or smaller than those which such words as huge, enormous, tiny, or minute are capable of expressing. And though an electric spark, even from our most powerful artificial sources, appears to the non-scientific trifling in comparison with a mile-long flash of lightning, the difference (huge, if you like to call it) is as nothing to others with which scientific men are constantly dealing. The nearest star is as much farther from us than is the sun, as the sun is farther from us than is London. The sun's distance is 93,000,000 of miles. If that distance be called enormous, and it certainly is so, what adjective have you for the star's distance? The particles of steam are as much less than a drop of water as an orange is less than the whole earth. How can you fitly characterise their smallness? Ordinary human language, and specially the more poetic forms of it, were devised to fit human feelings and emotions, and not for scientific purposes; for the imagination, not for the reason. As there is a limit alike to pleasure and to pain, so there is to wonder and astonishment; and with words expressive of something near these limits ordinary language rests content. A thoroughly scientific account of a thunderstorm, if it were possible to give one, would certainly be at once ridiculed as pedantic.

Let us therefore, instead of attempting to discuss the phenomenon as a whole, consider separately some of its more prominent features. And first of all, what are these features when we are *in* the thunderstorm?

By far the most striking, at least if the thunderstorm come on during the day, is the extraordinary darkness. Sometimes at midday in summer the darkness becomes comparable with that at midnight, and in another sense it much resembles midnight darkness, for it is very different in kind as well as intensity from that produced by the densest fog. Objects are distinctly visible through it at distances of many miles, whether when self-luminous or when instantaneously lit up by lightning. The darkness, then, is simply intense *shadow*, produced by the great thickness and great lateral extension of the cloud-masses overhead. This altogether unusual amount of cloud always forms a prominent feature in a great thunderstorm. We have thus obtained one very important clue to the origin of the phenomenon. In cases where the darkness is not so great, though the storm is visibly raging overhead, it is always observed either that we are not far from the edge of its area or, in rarer cases, that the lower cloud strata lie much higher than usual. These form, therefore, no exception to the general conclusion just given as to the abnormal amount of cloud present. Seen from a distance, the mass of cloud belonging to the storm usually presents a most peculiar appearance, quite unlike any other form of cloud. It seems to boil up, as it were, from below, and to extend through miles of vertical height. The estimated height of its lower surface above the ground varies within very wide limits. Saussure has seen it as much as three miles; and in one case noticed by De l'Isle it may have been as much as five miles. On the other hand, at Pondicherry and Manilla it is scarcely ever more than half a mile. Haidinger gives the full details of an extraordinary case, in which the thundercloud formed a stratum of only 25 feet thick, raised 30 yards above the ground. Yet two people were killed on this occasion. Other notable instances of a similar extreme character are recorded.

Careful experiment shows us that the air is scarcely ever free from electricity, even in the clearest weather. And even on specially fine days, when large separate cumuli are floating along, each as it comes near produces a marked effect on the electrometer. Andrews obtained by means of a kite, on a fine clear day, a steady decomposition of water by the electricity collected by a fine wire twisted round the string. Thanks to Sir W. Thomson, we can now observe atmospheric electricity in a most satisfactory manner. I will test, to show you the mode of proceeding, the air inside and outside the hall. [The experiment was shown, and the external air gave *negative* indications.]

On several occasions I have found it almost impossible, even by giving extreme directive force to the instrument by means of magnets, to measure the atmospheric potential with such an electrometer, and had recourse to the old electroscope, with specially long and thick gold-leaves. On February 26th, 1874, when the sleet and hail, dashing against the cupola of my class room, made so much noise as to completely interrupt my lecture, I connected that instrument with the water-dropper, and saw the gold-leaves discharge themselves against the sides every few seconds, sometimes with positive, sometimes, often immediately afterwards, with negative electricity. Such effects would have required for their production a battery of tens of thousands of cells. Yet there was neither lightning nor thunder, and the water was trickling from the can at the rate of only two and a half cubic inches per minute. Probably had there not been such a violent fall of sleet steadily discharging the clouds we should have had a severe thunderstorm. That this is no fancied explanation is evident from the fact that falling raindrops are often so strongly charged with electricity as to give a spark just before they touch the ground. On such occasions, when the fall occurs at night, the ground is feebly lit up. This "luminous rain," as it has been called, is a phenomena which has been over and over again seen by competent and trustworthy observers. In the *Comptes Rendus* for November, 1879, we read of the curious phenomenon of electrification of the observer's umbrella by a slight fall of snow, to such an extent that he could draw sparks from it with his finger.

In calm, clear weather the atmospheric charge is usually positive. This is very commonly attributed to evaporation of water, and I see no reason to doubt that the phenomena are closely connected. I will show you one of the experiments upon which the idea is based. I can take no other form of experiment than a somewhat violent one, as the effects of the more delicate ones could not easily or

Digitized by Google

certainly be made visible to so large an audience. [A few drops of water were sprinkled on a heated crucible, insulated, and connected with the electrometer.]

There can be no doubt that, whatever be the hidden mechanism of this experiment, the steam has carried with it a strong charge of positive electricity, for it has left the rest of the apparatus with a strong negative charge. We might reverse the subject of measurement by connecting the electrometer with the escaping steam, but I omit it, to save time, and because we will now try that form of the experiment in another way. [High-pressure steam escaping from a little boiler was made to play upon an insulated conductor furnished with spikes, and connected with the electrometer, which then showed a strong positive charge.]

There are many substances which produce on evaporation far greater electric developments than water does, some of positive, others of negative, electricity. By far the most remarkable in this respect to which attention has yet been called is an aqueous solution of sulphate of copper. (*Proc.* R.S.E., 1852.) The smallest drop of this solution thrown on a hot dish gives an intense negative effect—so great, in fact, that it may be occasionally employed to charge a small Leyden jar. But this, like the smaller effect due to water under similar circumstances, is not yet completely explained.

The next striking features are the flashes of lightning, which at intervals light up the landscape with an intensity which must in the majority of cases far exceed that produced by the full moon. To the eye, indeed, the flash does not often appear to furnish more than the equivalent of average moonlight, but it must be remembered that it lasts for a period of time almost inconceivably short, and that the full effect of light on the eye is not produced until after the lapse of a considerable fraction of a second. Professor Swan has estimated this interval at about one-tenth of a second; and he has proved that the apparent intensity of illumination for shorter intervals is nearly proportional to the duration. (*Trans.* R.S.E., 1849.) I can illustrate this in a very simple manner. [Two beams of light were thrown upon the screen by reflection from mirrors, each of which was fixed *nearly* at right angles to an axis. When matters were so adjusted that the brightness of the two illuminated spots was the same, one mirror was made to rotate. The corresponding light spot described a circle about the other, and the brightness of its track became less the larger the circle in which it was made to revolve.] The lightning flash itself on this account, and for the farther reason that its whole apparent surface is exceedingly small, must be in some degree comparable with the sun in intrinsic brilliancy—though, of course, it cannot appear so. The fact that its duration is excessively short is easily verified in many ways, but most simply by observing a body in rapid motion. The spokes of the wheels of the most rapidly-moving carriage appear absolutely fixed when illuminated by its light alone. One can read by its light a printed page stuck on a disc revolving at great speed. But the most severe test is that of Sir Charles Wheatstone's revolving mirror. Seen by reflection in such a mirror, however fast it may be rotating, a flash of lightning is not perceptibly broadened, as it certainly would be if its duration were appreciable.

The apparatus which, in our laboratories, enables us to measure the time which light, moving at nearly 200,000 miles per second, takes to pass over a few feet, is *required* to prove to us that lightning is not absolutely instantaneous. Wheatstone has shown that it certainly lasts less than a millionth part of a second. Take this, along with Swan's datum, which I have just given you, and you see that the apparent brightness of the landscape, as lit up by a lightning flash, is *less than one hundred thousandth part* of what it would be were the lightning permanent. We have thus rough materials for instituting a comparison between the intrinsic brightness of lightning and of the sun, and it is well to notice that this exceedingly brief duration saves us from serious injury to the sight, if not from total blindness, which would certainly result from a near and powerful flash if it lasted for one-tenth of a second.

Transient in the extreme as the phenomenon is, we can still, in virtue of the duration of visual impressions, form a tolerably accurate conception of the form of a flash; and in recent times instantaneous processes of photography have given us permanent records of it. Some of these are given in *La Nature*, December, 1883. These, when compared with photographic records of ordinary electric sparks, bear out to the full the convictions at once forced by appearances on the old electricians, that a flash of lightning is merely a very large electric spark. The peculiar zigzag form, sometimes apparently almost doubling back on itself, the occasional bifurcations, and various other phenomena of a lightning flash, are all shown by the powerful sparks from an electric machine. [These sparks were exhibited directly; and then photographs, of which one is represented in the woodcut (Fig. 1), were exhibited.]

But the spectroscope has recently given us still more convincing evidence of their identity, if any such should be wanted. This is a point of great importance, but I have not now time to discuss it. Thus, though on a very small scale comparatively, we may study the phenomena of lightning at convenience in our laboratories.

We thus know by experiment that electricity chooses always the easiest route, the path of least resistance. Hence the danger of taking the otherwise most natural course of standing under a tree during a thunderstorm. The tree, especially when wet, is a much better conductor than the air, and is consequently not unlikely to be chosen by the discharge; but the human body is a conductor much superior to the tree, and therefore is chosen in preference so far as it reaches. The bifurcations of a flash can puzzle no one who is experimentally acquainted with electricity, but the zigzag form is not quite so easily explained. It is certainly destroyed, in the case of short sparks, by heating the air. [Photographs of sparks in hot and in cold air were exhibited. One of each kind is shown in the woodcut (Fig. 2). The smoother is that which passed through the hot air. The other passed through the cold air nearer the camera, and is therefore not quite in focus.]

FIG. 1.

Now heating in a tube or flame not only gets rid of motes and other combustible materials, but it also removes all traces of electrification from air. It is possible, then, that the zigzag form of a lightning flash may, in certain cases at least, be due to local electrification, which would have the same sort of effect as heat in rarefying the air and making it a better conductor.

A remark is made very commonly in thunderstorms which, if correct, is obviously inconsistent with what I have said as to the extremely short duration of a flash.

Even if we supposed the flash to be caused by a luminous body moving along, like the end of a burning stick whirled around in a dark room, it would pass with such extraordinary rapidity that the eye could not possibly follow its movements. Hence it is clear that when people say they *saw* a flash go upwards to the clouds from the ground, or downwards from the clouds to the ground, they must be mistaken. The origin of the mistake seems to be a *subjective* one—viz., that the central parts of the retina are more sensitive, by practice, than the rest, and therefore that the portion of the flash which is seen directly affects the brain sooner than the rest. Hence a spectator looking towards *either* end of a flash very naturally fancies that end to be its starting point.

Before I can go farther with this subject it is necessary that I should give some simple facts and illustrations connected with ordinary machine electricity. These will enable you to follow easily the slightly more difficult steps in this part of our subject which remain to be taken.

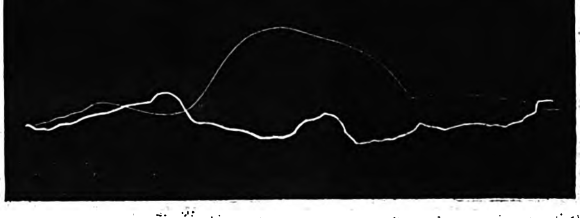

FIG. 2.

Since we are dealing mainly with *motion* of electricity, it is necessary to consider to what that motion is due. You all know that winds, *i.e.*, motions of the air, are due to differences of pressure.

If the pressure were everywhere the same at the same level we should have no winds. Similarly the cause of the motion of heat in a body is difference of temperature. When all parts of a body are at the same temperature there is no change of distribution of heat. Now electricity presents a precisely analogous case. It moves in consequence of difference of *potential*. Potential, in fact, plays, with regard to electricity, a part precisely analogous to the *rôle* of pressure, or of temperature, in the case of motions of fluids and of conducted heat. It would tax your patience too much were I to give an exact definition of potential in a lecture like this; but you may get a sufficiently approximate notion of it in a very simple way—again by analogy. Suppose I wished to specify the power of the pump used to compress air in an air-gun receiver. I

Digitized by Google

should say it can produce a limiting pressure of 40 or 100 atmospheres, as the case may be. If you try to go any farther it leaks. This would be considered quite definite information. But, mark you, nothing is said as to the *capacity* of the receiver. When the pump has done its utmost, the receiver, be it large or small, contains air at the definite pressure of the 40 or 100 atmospheres which measure the power of the pump.

A longer time will be required for a more capacious receiver, but the ultimate pressure is the same in all. And when two receivers contain air at the same pressure you may open a communication between them, but no air will pass, however much they may differ in capacity. Similarly, you may measure the power of a flame or a furnace by the highest temperature it can produce. It will take a longer time to effect this the greater is the thermal capacity of the body to be heated; but when two bodies are at the same temperature no heat passes from one to the other. Similarly, the power of an electrical machine may be measured by the utmost potential it can give to a conductor. The greater the capacity of the conductor the longer time will be required for the machine to charge it; but no electricity passes between two conductors charged to the same potential. Hence the power of a machine is to be measured by using the simplest form of conductor, a sphere, and finding the utmost potential the machine can give it. It is easily shown that the potential of a solitary sphere is directly as the quantity of electricity, and inversely as the radius. Hence electricity is in equilibrium on two spheres connected by a long thin wire when the quantities of electricity on them are proportional—not to their surfaces, nor to their volumes, as you might imagine—to their radii. In other words, the capacity is proportional to the radius. This, however, is only true when there are no other conductors within a finite distance. When a sphere is surrounded by another concentric sphere, which is kept in metallic connection with the ground, its capacity is notably increased, and when the radii of the spheres are nearly equal the capacity of the inner one is directly as its surface, and inversely as the distance between the two spheres. Thus the capacity is increased in the ratio of the radius of one sphere to the difference of the radii of the two, and this ratio may easily be made very large. This is the principle upon which the Leyden jar depends.

We may usefully carry the analogy of the pump a good deal further. Supposing the piston to be fully pressed home every stroke, the amount of work spent, even if the whole be kept cool, on each stroke continually increases, so that about two and a half times as much work is required to charge the receiver to 40 atmospheres as to 20. The same holds with electricity. Each successive unit of the charge requires more work to force it in than did the preceding one, because the repulsion of all already in has to be overcome. It is found, in fact, that the work required to put in a charge is proportional to the square of the charge. Of course less work is required for a given charge the greater is the capacity of the receiver. Conversely, the damage which can be done by the discharge, being equal to the work required to produce the charge, is proportional to the square of the charge, and inversely to the capacity of the receiver. Or, what comes to the same thing, it is proportional to the square of the potential and to the capacity of the conductor directly. Thus a given quantity of electricity gives a greater shock the smaller the capacity of the conductor which contains it. And two conductors, charged to the same potential, give shocks proportional to their capacities. But in every case, a doubling of the charge, or a doubling of the potential, in any conductor, produces a fourfold shock.

The only other point I need notice is the nature of the distribution of electricity on a conductor. I say *on* a conductor, because it is entirely confined to the surface. The law is—it is always so arranged that its attractions or repulsions in various directions exactly balance one another at every point in the *substance* of the conductor. It is a most remarkable fact that this is always possible, and in every case in one way only. When the conductor is a single sphere the distribution is uniform. When it is elongated the quantity of electricity per square inch of its surface is greater at the ends that in the middle; and this disproportion is greater the greater is the ratio of the length to the transverse diameter. Hence on a very elongated body, terminating in a point, for instance, the electric density—that is, the quantity per square inch of surface—may be exceedingly great at the point while small everywhere else. Now, in proportion to the square of the electric density is the outward pressure of the electricity tending to escape by forcing a passage through the surrounding air. It appears from experiments on the small scale which we can make with an electrical machine, that the electric density requisite to force a passage through the air increases under given circumstances, at first approximately as the square root of the distance which has to be traversed, but afterwards much more slowly, so that it is probable that the potential required to give a mile long flash of lightning may not be of an order very much higher than that producible in our laboratories.

But from what I have said you will see at once that under similar circumstances an elongated body must have a great advantage over a rounded one in effecting a discharge of electricity. This is easily proved by trial. [The electric machine being in vigorous action, and giving a rapid series of sparks, a pointed rod connected with the ground was brought into the neighbourhood, and the sparks ceased at once.] In this simple experiment you see the whole theory and practical importance of a lightning conductor. But, as a warning, and by no means an unnecessary one, I shall vary the conditions a little and try again. [The pointed rod was now insulated, and produced no observable effect.] Thus you see the difference between a proper lightning-rod and one which is worse than useless, positively dangerous. There is another simple way in which I can destroy its usefulness—namely, by putting a little glass cap on the most important part of it, its point, and thus rendering impossible all the benefits it was originally calculated to bestow. [The pointed rod was again connected with the ground, but furnished with a little glass cap. It produced no effect till it was brought within four or five inches of one of the conductors of the machine, and then *sparks* passed to it.] You must be strangely well acquainted with the phases of human perversity if you can anticipate what I am now going to tell you, namely, that this massive glass cap, or *repeller*, as it was fondly called, was only a year or two ago taken off from the top of the lightning-rod employed to protect an important public building. [The repeller was exhibited. It resembled a very large soda-water bottle with a neck much wider than the usual form.] From the experiments you have just seen it must be evident to you that the two main requisites of an effective lightning-rod are that it should have a sharp point (or, better, a number of such points, lest one should be injured), and that it should be in excellent communication with the ground. When it possesses these, it does not require to be made of exceptionally great section; for its proper function is *not*, as is too commonly supposed, to parry a dangerous flash of lightning; it ought rather, by silent but continuous draining, to prevent any serious accumulation of electricity in a cloud near it. That it may effectually do this it must be thoroughly connected with the ground, or (if on a ship or lighthouse) with the sea. In towns this is easily done by connecting it with the water mains, at sea by using the copper sheathing of the the ship, or a metal plate of large surface fully immersed. Not long ago a protected tower was struck by lightning. No damage was done in the interior, but some cottages near its base were seriously injured. From a report on the subject of this accident it appears that the lower end of the lightning-rod was "jumped" several feet into the solid rock! Thus we see, in the words of Arago, how "False science is no less dangerous than complete ignorance, and that it *infallibly* leads to consequences which there is nothing to justify."

That the lightning-rod acts as a constant drain upon the charge of neighbouring clouds is at once proved when there is, accidentally or purposely, a slight gap in its continuity. This sometimes happens in ships, where the rod consists of separate strips of metal inlaid in each portion of the mast. If they are not accurately fitted together, a perfect torrent of sparks, almost resembling a continuous arc of light, is seen to pass between whenever a thunderstorm is in the neighbourhood.

I cannot pass from this subject without a remark upon the public as well as private duty of having lightning-rods in far greater abundance than we anywhere see them in this country. When of proper conducting power, properly pointed, properly connected with the ground and with every large mass of metal in a building, they afford absolute protection against ordinary lightning—every single case of apparent failure I have met with having been immediately traceable to the absence of one or other of these conditions. How great is their beneficial effect you may gather at once from what is recorded of Pietermaritzburg, viz., that till lightning-rods became common in that town it was constantly visited by thunderstorms at certain seasons. They still come as frequently as ever, but they cease to give lightning flashes whenever they reach the town, and they begin again to do so as soon as they have passed over it.

A knight of the olden time in full armour was probably as safe from the effects of a thunderstorm as if he had had a lightning-rod continually beside him; and one of the Roman emperors devised a perfectly secure retreat in a thunderstorm in the form of a subterraneous vault of iron. He was probably led to this by thinking of a mode of keeping out missiles, having no notion that a thin shell of soft copper would have been quite as effective as massive iron. But those emperors who, as Suetonious tells us, wore laurel crowns or sealskin robes, or descended into underground caves or cellars on the appearance of a thunderstorm, were not protected at all. Even in France, where special attention is paid to the protection of buildings from lightning, dangerous accidents have occurred where all proper precautions seemed to have been taken. But on more careful examination it was usually found that some one essential element was wanting. The most common danger seems to lie in fancying that a lightning-rod is necessarily properly connected with the earth if it dips into a mass of water. Far from it.

Digitized by Google

A well-constructed reservoir full of water is *not* a good "earth" for a lightning-rod. The better the stonework and cement the less they are fitted for this special purpose, and great mischief has been done by forgetting this.

A few years ago the internal fittings of the lighthouse at Skerryvore were considerably damaged by lightning, although an excellent lightning-rod extended along the whole height of the tower. But a long copper stove-pipe, rising through the whole interior of the tower, and the massive metallic ladder rising from the ground to the lowest chamber, though with a considerable gap between them, offered less resistance than the rod, and the lower end of the ladder was nearer to the sea than was the pool on the reef into which the lightning-rod plunged. Hence the main disruptive discharge took place from the stove-pipe to the ladder, blowing the intervening door to pieces. The real difficulty in these situations, exposed to tremendous waves, lies in effecting a permanent communication between the lightning-rod and the sea. But when this is done the sea makes far the best of "earths,"

When a lightning-rod dircharges its function imperfectly, either from insufficient conducting power or because of some abnormally rapid production of electricity, a luminous brush or glow is seen near its point. This is what the sailors call St. Elmo's Fire, or Castor and Pollux. In the records of mountain climbing there are many instances of such discharges to the ends of the alpenstocks or other prominent pointed objects. One very remarkable case was observed in 1879 in Switzerland, where at dusk, during a thunderstorm, a whole forest was seen to become luminous just *before* each flash of lightning, and to become dark again at the instant of the discharge.

Perhaps the most striking of such narratives is one which I will read to you from the memoirs of the Physical and Literary Society, from which about a century ago sprang the *Royal Society of Edinburgh*. These essays are rare and curious, and the names of Maclaurin, James and Matthew Stewart, Whytt, and Monro appear among their authors.

The following observations on Thunder and Electricity, by Ebenezer McFait, M.D., show how, in the search for truth, men may unwittingly put themselves in the gravest danger :—

"The experiment proposed by Mr. Franklin to prove that lightning and the electrical fire are the same has often been repeated with success, both in England and abroad, so that the most noted electrical experiments have been performed by fire drawn from the clouds.

"Mr. Franklin also first discovered that sharp points attract and discharge the electrical matter most copiously; and from thence supposes that a very sharp-pointed rod, fixed to the extremity of the topmast of a ship, with a wire conducted down from the foot of the rod round one of the shrouds and over the ship's side into the sea, would silently lead off the electrical fire, and save the ship from thunder in hot countries; and that by a similar method buildings might be preserved.

"So useful a proposal deserves to be examined; variety of experiments may give hints for new improvements. For this reason the following observations are communicated, though not so complete as might be wished, being the result of one trial only.

"It seldom thunders in this northern clime. In June, 1752, there seemed to be some thunder at a distance from Edinburgh; but from the beginning of July to the beginning of October we had nothing almost but continual rains. The last summer was uncommonly warm and dry; and yet we had only a few claps of thunder at Edinburgh, one evening, and my attempts for making any of those experiments were entirely unsuccessful until Saturday night, September 15, when we had a very great storm.

"I used a round iron rod, two-tenths of an inch diameter, about 11ft. long, sharpened at one end; the other end was inserted in a glass tube, and that tube stood in a common glass bottle, which I held in my hand.

"I used also another rod about three feet long, sharpened in like manner at one end, which stood with the other end in a glass tube, which was stuck in the ground. I began upon the Calton Hill. The lightning and fire in the air abounded greatly, and yet it was some time before anything else appeared. At last some rain began to fall, and the air turned moister, then fire appeared upon the extremities of each of the rods in a small pretty blaze, very like the fire which is discharged from the point of a sword in the dark, when the person that holds it is electrified, and stands upon glass or resin; or like that which appears upon any sharp point when presented to an electrified gun barrel, but in greater quantity. I touched the long rod with my finger, but had no sparks from it. The short rod was accidentally taken out of its tube, and yet continued to burn and blaze as formerly. In like manner the flame continued upon the end of the long rod, though I took hold of it anywhere at pleasure above the glasses, until I moved my hand or finger along within a few inches of the flame; then it was attracted by my hand, and vanished.

"I went from the Calton Hill to the Castle Hill at the other end of the town, and in passing through the streets no fire appeared upon either of the rods; but almost immediately when I got clear of the houses upon the open hill the point of the longer iron rod took fire. In the dark I had lost the tube belonging to the shorter rod, and the point of it did not catch fire when the longer one was kindled. Perhaps I did not wait long enough for a proper trial, for I soon touched the flame upon the long rod with the sharp point of the short one, and then it also took flame, and continued burning as before without any further dependence upon the longer one.

"I held the shorter rod by the sharp end and approached the blunt end of it to the flame upon the point of the longer rod; then this blunt end caught the fire, and the flame upon the points of the two rods continued rather stronger than on the single one before, so long as I kept them in contact, and the fires within three or four inches of one another; but when I drew them farther asunder the flame upon the extremity of the blunt rod vanished. This happened as often as I tried it, and it is evident that in like manner I could have got the fire to fix upon the points of a great many rods, and so have had them all flaming together. Once or twice a flash of lightning seemed to dart directly against the point of the rod; then the fire, as I thought, expanded itself and united with the lightning, but it immediately began to shine again when the lightning was past.

"Though it rained much in time of these observations, yet the fire upon the ends of the rods did not go out until it became so heavy as if it were pouring down out of funnels.

"After this I went home for some time, resolving to come abroad again when the storm was more tolerable; but it continued to rain all night so violently that I was obliged, with regret, to leave several experiments to the chance of some future opportunity. For example, I suspected that the glass tubes had not been of great use on this occasion, and wanted to have tried whether I should have had the same appearances by using the rods alone, without any other apparatus. This is very probable, as also that the glasses, by being wet, allowed the electrical fire to flow off as it was attracted.

"I beg leave to add a few remarks relative to this subject. It would seem that experiments of this kind may be made without danger when the thunder is at a moderate distance. The lightning expands itself, as it flies, and by expansion loses its vigour. Perhaps there is one simple and easy way of protecting masts and spires from thunder, viz., to fix horizontally upon the highest parts of them a flat round piece of wood, of a foot diameter or more, in order to prevent those blazing fires from fixing upon them, and accumulating.

"This storm passed directly over Edinburgh, and came on from the south by west, as nearly as could be estimated. There was a great deal of lightning that night, above sixty miles to the westward, but no thunder heard. At Glasgow there was very much lightning, and a few distant faint claps of thunder. On the road from Belford or Berwick it lightened incessantly, but two claps of thunder only were heard, and those very faint, so that there is reason to think that the fire of this storm spread over the breadth of 130 miles at least. I wish I could also give some account where this thunder began, and how far it ran before it was extinguished.

(TO BE CONTINUED.)

INSTALLATION OF THE B.T.K. SYSTEM OF ELECTRIC LIGHTING AT COLCHESTER.

On Wednesday, the 11th inst., at the invitation of the South Eastern Brush Electric Light and Power Company, a large number of gentlemen interested in electric lighting operations, went to Colchester to see the system adopted for the house-to-house lighting which is being carried out by this Company. The system is known as the B.T.K. system, having been devised by Messrs. Beeman, Taylor, and King, engineers to the Company. Previous to visiting the central and other stations, a meeting was held at the town hall, at which the chairman of the Company, Sir Michael Kennedy, presided. At this meeting Mr. King read a paper which he had prepared, describing the work and apparatus at Colchester. Previous to the reading of this paper the chairman stated that, so far as he was aware, Colchester might claim to be the first town, at any rate in England, where a system of house-to-house lighting had been installed; and at any rate the system about to be described had, he knew, not been adopted elsewhere. Thus Colchester would in future claim the proud position of being first in the field. He spoke very highly of the manner in which the efforts of the Company had been seconded by the mayor and the local authorities of Colchester. Every possible aid had been rendered in the work, and much of the success was due to the assistance thus rendered. The chairman mentioned that amongst the visitors was a deputation from the Commissioners of Sewers, from London, as well as the mayors and other officials from various local authorities, amongst which might be mentioned Brighton and Dublin. It was also pointed out that the restrictions of the Board of Trade had been rigidly complied with. Mr. King, one of the electricians responsible for this system, then read the following paper. It may be

Digitized by Google

well to say that the paper was illustrated by the actual apparatus used, some of which we described and illustrated in *The Electrician* of March 8, 1884. The paper of Mr. King was as follows :—

I endeavour to show that the principle of *centralisation* has been one of the stumbling blocks in the way of the practical development of electric lighting over large areas. One of the aims of the system which we have commenced to install in Colchester is *decentralisation* in the broadest sense of the word as far as regards the station from which the supply of electricity is given, and the other is to make the supply entirely independent of the moving machinery, so as to avoid the liability to sudden stoppages from any cause. A cursory examination of the problem of electric lighting direct from the dynamo machine will show that the maintenance of a standard electromotive force or pressure, with an allowance of, say, 5 or 6 per cent. variation when large currents, such as would be required for, say, 600 or 700 incandescent lamps, are driven along even moderate lengths of conducting cable, would entail the use of perfectly compounded dynamo machines, very costly conductors, and engines fitted with almost absolutely accurate or perfect governing gear, such as, I am sorry to say, have not yet been invented. I will briefly describe the machinery and apparatus concerned in the production, storage, and supply of electricity on the B. T. K. system, the distinctive features of which are the use of secondary batteries or accumulators placed in favourable positions for reducing the length and dimensions of conducting cables ; dynamo machines capable of generating electric currents of any high electromotive force or pressure, so as to charge a large number of these secondary batteries at one time, although situated at a long distance from the dynamo or generating station ; rocking switches—actuated by a special cell, being one of any set of secondary batteries, and called the master cell, which break the charging circuit when the operation of charging is completed, and which shunt the stored current (if I may be permitted to use such a term) on to the mains and service wires for the supply to consumers, and which at the same time converts the high electromotive force which existed during the charging process to the standard E.M.F. required by the lamps in use. For this purpose there are alternate sets of batteries and rocking switches, so that while one set of batteries is being charged the other set is in supply, and by the time the maximum current is required, say, in the evening, both sets of batteries will have been fully charged, and will therefore have been cut out of the charging circuit, and will be connected to the supply mains. This alteration of sets in charge and supply is made quite automatic, so as to require no attention to this part of the plant beyond an occasional inspection. The engine for driving the dynamo machines was built by Messrs. Davey, Paxman and Co., of Colchester, and is of 25 horse-power nominal, semi-portable type, is capable of exerting 90 horse-power when working at 133 revolutions per minute. It is connected by belting from the fly-wheel, which is 7ft. in diameter, to a 4ft. 6in. pulley on the countershaft, and from pulleys of 5ft. diameter on the countershaft, by belting, to two No. 8 Brush dynamo machines. These are the largest machines of this type at present made, but a demand for machines giving twice the current at the same or a higher E.M.F. will no doubt be met as required. The machines at present in use give a current of 9·5 to 10 amperes at an E.M.F. of about 1,800 volts when rotated at a speed of 700 to 750 revolutions per minute. They are connected together in what is known as parallel arc, or for quantity—thus acting as one machine, and giving a current up to nearly 20 amperes. Some little difficulty was at first experienced in arranging the two machines for running together, so that each produced its quantum of the work, and so balanced the work of the other. The machines being originally constructed for arc lighting, also required some modification to convert them to their present purpose, and they are therefore separately excited by means of a small Victoria dynamo, which passes a current of about 10 amperes round the field magnet coils of each, and so excites the magnetic field in which the armature rotates. This Victoria dynamo machine was constructed to specification by the Anglo-American Brush Corporation for the South Eastern Brush Company, and gives an E.M.F. of 150 volts when working through an external resistance of 7·5 ohms. This method of excitation of the magnetism allows of great adjustment of the strength of the magnetic field, so that the power expended in charging less than the maximum number of cells is nearly proportional to the number in charge at any time. The adjustment of the strength of the magnetic field of the large machines to the requirements of the circuit is accomplished by means of an automatic regulator, which limits the supply of current to the field magnet coils in the large machines. It consists of two electro magnets, the armatures of which actuate contact-breaking apparatus in connection with a small electric motor, and which cause the armature of the motor to rotate in either direction, according to the manner in which the connection is made with the source of supply. The rotation of the armature of this motor then actuates a sliding contact, which increases or decreases the resistance in the field magnet circuit of the Victoria machine. The charging current is passed through the coils of the electro-magnets of the regulator, and fluctuations in the current have their effect on the armatures, causing them to be attracted or released according as the current is above or below the normal amount. When, in consequence of an excess in the charging current, one of the armatures is attracted to its electro-magnet, connections are made to the motor in such manner as to cause its armature to rotate, and so actuate the sliding contact, and add resistance in the field magnet circuit of the Victoria machine. This decreases the electromotive force generated, and thus lowers the current in the field magnet coils of the large machines until the strength of the charging current is again brought to its normal. The generation of currents of high electromotive force by means of the Brush dynamo machine presents some difficulties when it is necessary that the maximum E.M.F. should be available at any instant. This arises from the fact that the current generated by these machines is not absolutely continuous, but is a series of waves or pulsations caused by the commutation of the current in which the circuit is broken three times in each revolution of the armature. As a result of this peculiarity it is impossible to run the machine in open circuit when separately excited, and to obviate this difficulty a switch and resistance was constructed. The switch is mounted on a board carrying three current metres. One of these shows the amount of current circulating in the coils of the field magnets of the large machines, another shows the current passing in the resistance coils, and the last shows the current passing in the charging circuit. The first portion of the switch carries the current generated by the large dynamos through the resistance coils, and the amount of resistance in ohms being multiplied by the reading of the current meter gives the value of the electromotive force generated in volts, and on this reaching its maximum the switch is moved to the second position, and the current then passes into the charging circuit. The resistance coils also serve to load the engine up to the amount of work required from it, and thus prevents the pull up and consequent strain which would take place where, from running almost light, a load of 80 horse-power were suddenly put upon it. From the resistance coils and switch and meter board we come to the rocking switch, by means of which we are able to conform to the terms of the license of the Board of Trade under the Electric Lighting Act, 1882. One of the clauses of the license prohibits the introduction of electromotive force of more than 200 volts into the houses of consumers, and although 2,000 or 3,000 volts may be used for the purpose of charging, this apparatus limits the force in the supply mains to the standard pressure required by the lamps in use, which in the case of Colchester is 60 volts. With this apparatus the accidental presence of high E.M.F. in houses is an impossibility, as at the instant of breaking the circuit, either of charge or supply, both circuits will be interrupted for a moment. The rocking switch consists of two rows of 18 iron cups containing mercury, mounted at opposite ends of an insulating base. In the centre of this base a cradle is fixed, in which the rocking bar carrying the contact pieces is suspended by steel centres. Sixteen of the cups at one end of the base are connected alternately with the positive and negative poles of the cascades of batteries ; the two remaining cups at this end being connected respectively to the positive and negative poles of the charging main. Connections are made on the under side of the base from the 16 alternate positive and negative cups to 16 of the cups at the other end of the base, so as to make eight cups on one side positive and the remaining eight negative. A pair of large cups, one at each side, carry the whole of the current to the positive and negative supply mains. The contact pieces carried by the rocking bar are in the form of prongs which dip into the mercury cups. On the charging side they are in detached pairs mounted on an ebonite bar, so as to connect the positive end of one cascade of batteries to the negative end of the next cascade, and so on. On the supply side the contact prongs are mounted on two copper bars connecting all the positive ends of the cascades to one bar and terminal mercury cup, and all the negative ends to the other bar and cup, and from these terminal cups to the supply mains, as before explained. The rocking switches are actuated by automatic means which throw the batteries out of the charging circuit, when the charging process is completed, or so near completion that free hydrogen is rapidly evolved from the positive electrodes, and this operation is carried out by means of the master cell. This master cell is one of the ordinary battery cells to which a simple arrangement is made for collecting the gas given off from one of the positive electrodes of the cell. The gas is collected in an air-tight chamber which partially encloses one of the positive plates, and which extends a short distance below the level of the dilute acid in the cell. In the top of this chamber is an orifice, in which is inserted a tube carrying a loose diaphragm, which is also made perfectly air-tight. On the top of this diaphragm a plunger rests, and this plunger actuates by its rise and fall, according to the distension or contraction of the diaphragm, a small contact-breaker, which makes or breaks a circuit through the electro-magnet which actuates the rocking switches. It is evident, then, that on completion of the charging process and consequent distension of the diaphragm by the free gas evolved, the charging current will be interrupted, and the current energy stored in the batteries will be made available for supply by the fall of the bar carrying the contact pieces or prongs on the discharge side of the rocking switch. The secondary action due to the electrolysis of dilute sulphuric acid with lead electrodes has been studied by Planté since 1859, and it is from his published experiments that all of the many forms of accumulators have sprung. But the form of electrode used in the B.T.K. batteries made by the Consolidated Electric Company has several features rendering it distinct from any other form. The principle of the plate is the use of a band or tape of lead, cut from the sheet by machinery, which renders one side of the tape cellulated or roughened. In the latest form we use a number of very thin tapes, cut as described, and a thicker tape wound or coiled upon them to the required dimensions and pressed into shape. It is then burnt together at the corners to give rigidity when fitted with a cast-lead support or pole-piece. It is then ready for "forming." This "formation" is the name given to the process which the plate undergoes to render it capable of receiving and storing the energy expended in driving the dynamo machine while performing chemical work by the electrolysis of the dilute sulphuric acid. Each cell of the battery contains eleven plates, the supports of which are connected alternately to copper bars on the outside of the cell ; and the copper bars are then provided with a hook attachment for connecting the cells together. They are supported on cast-iron racks, which rest on porcelain insulators on the ground, thus securing very perfect insulation and freedom from danger of making earth. They can be constructed of any capacity up to 360 ampere-hours, the capacity depending on the degree of formation and the thickness of the active material of the plates.

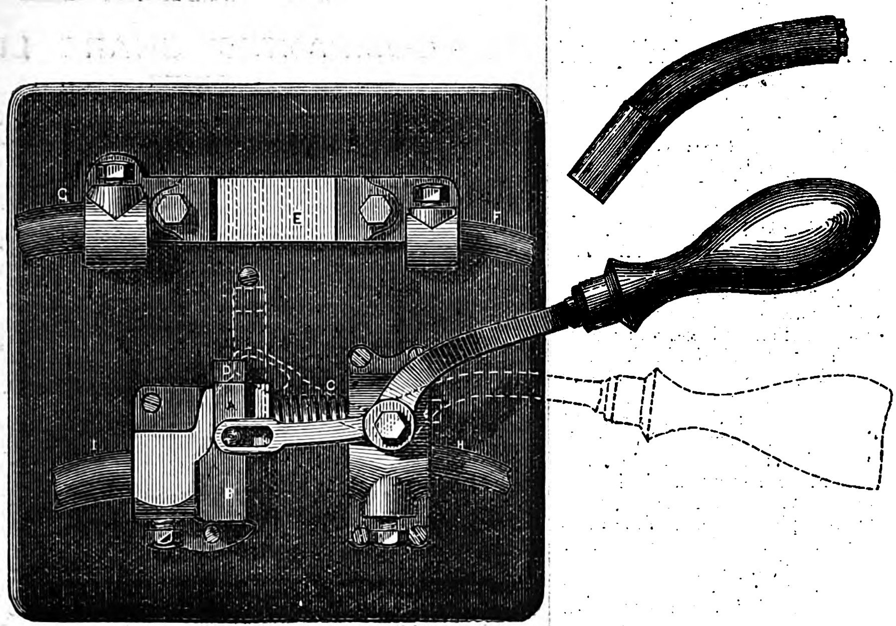
From consideration of the batteries, we come to the question of cables. It is on this ground that one of the claims of the B.T.K. system for economy rests. If it had been decided to light this district of Colchester on

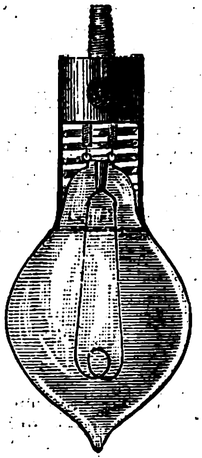
Digitized by Google

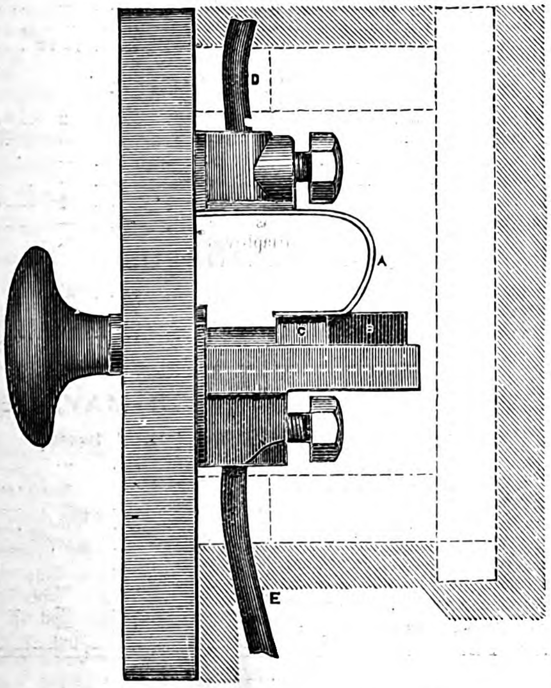
what is known as the parallel system, direct from the dynamo machine, we should have been compelled to spend a very large sum of money in cables, and this I hope to prove by the following simple calculation. We will divide our consideration of the cables necessary for the direct parallel system into two parts :—

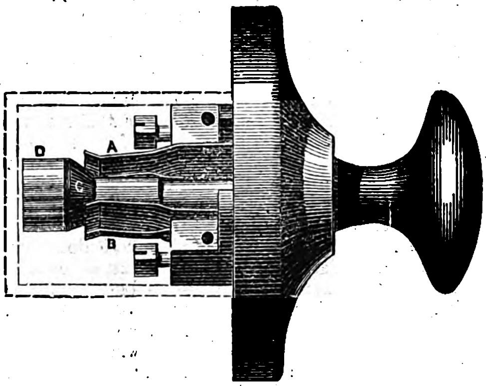
1st. The cable for carrying the whole current from the generating station to the supply mains in Head-street and High-street.

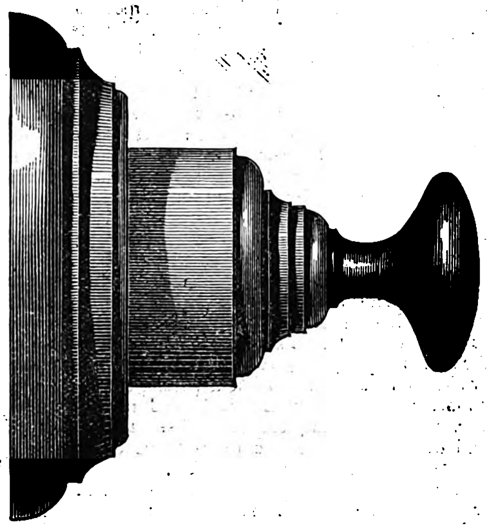
positions. The average length of each branch, lead and return, will be about 333 yards. Now, as the total current required would be about 2,000 amperes, we have to transmit along each branch 666 amperes; a maximum of 2 per cent. fall in the electromotive force is the utmost allowable in this part of the circuit, and on a 60-volt circuit this would amount to 1·2 volts. The resistance of the largest cable we use is about $\frac{1}{7}$ or ·145 ohm per 1,000 yards, and if we used this size for our three











Our diagrams show several forms of switches made by the Consolidated Electric Company, together with their incandescent lamp.

2nd. The supply mains in Head-street and High-street. We will suppose that the supply is to be equally distributed along the whole area, and on both sides of the road.

1st. The cables for carrying the whole current. This would be in, say, three branches from the station in Culver-street; one branch would go to Head-street, and the two others to High-street in the most favourable

branches, we should have a resistance in each of say $\frac{1}{20}$, or nearly ·048 ohm. But to pass 666 amperes through such a conductor as this would be impracticable, on account of heating; besides which it would take an electromotive force equal to 666 × ·05, or 33·3 volts. Our allowance for fall being limited to 1·25 volt, we should have to use a cable the copper conductor of which would equal the sectional area of 27 cables such as the

Digitized by Google

largest we use, and the weight of the cable would be about 25 tons. This would cost at least £3,000 or £4,000.

2nd. The mains for supply in High-street and Head-street.—The total length required would be about 5,000 yards, which would be divided, or may be considered as divided, into twelve branches of equal length, each branch being about 416 yards in length, and supplying a maximum current of 166 amperes, with an allowance for variation in E.M.F. of, say, 2½ per cent. The resistance of 416 yards of this 19 No. 12 B.W.G. cable will be about ·06, and to calculate the fall in E.M.F. when using this cable we must multiply 166 by ·06, giving 9·96 volts. But as the current is supposed to be equally distributed this amount will be divided by 2, and we should have a maximum fall of about 5 volts instead of 1·25. From this it will be seen that a cable would have to be used which would equal in sectional area $\frac{5}{1\cdot25}$, or four of these 19 No. 12 B.W.G. cables. Now, as this size costs about £200 per 1,000 yards, it is fair to assume that a cable four times the weight would cost at least three times as much, or about £750 per 1,000 yards, and as the total length is about 5,000 yards the cost will be about £3,800, making in all a grand total for cable of £7,000 or £8,000. I cannot better contrast the cost of cables on the two systems than by the statement that the whole for the supply of 2,000 incandescent lamps on the B.T.K. system have cost about £1,200. The figures speak for themselves, and need no further comment.

The cables as laid for the B.T.K. system are in twenty-one parallels, each distinct from the other, and branching from six battery stations. This division enables us to avoid the use of distributing boxes and also to test any length independently of the rest. They are laid in a brick trench built directly under the pavement, and having wells at distances of fifty feet apart to allow of drainage. The internal dimensions of the trench are 9in. by 7½in., which is ample space for three or four times the amount of cable laid. The road crossings are taken below the surface of the road, and the channel is here supplied with a cast-iron cover made in short lengths and with lap joints. The whole plan is seen at a glance by inspection of the diagrams, and it will be evident that such channelling offers great advantages over the use of iron or other pipes, as the cables can be reached at any place by simply raising a paving stone when junctions for services are requisite, and the pavement can be made good again in less than an hour. One of the regulations to be observed in relation to the supply of electricity under license from the Board of Trade is that:—"In each conductor of each service line shall be inserted a safety fuse of safety connection of a pattern to be approved by the Board of Trade, and which shall be easily accessible." Another rule is:—"That the supply shall be given from two poles situate at not less than three inches from each other, also to be of a pattern to be approved by the Board of Trade." We have here a small box enclosing a combination of safety fuse and service poles, which we think answers to all the reasonable requirements that may be made in this direction, but there can be little doubt that experience will point to some improvements which should be made. The practical limits of utility of a safety fuse or cut-out are that it shall effectively interrupt the passage of the current before any damage can occur to the insulation of the wires by heating consequent on the occurrence of a short circuit. I venture to say that the use of *very* delicate cut-outs of any kind would do more to bring electric lighting into disrepute than anything short of continual breakdowns. For this reason we use lead wire fuses mounted in heavy brass terminals, which, while keeping the fuse cool, will yet allow of the sudden rupture of the circuit when the current reaches a dangerous amount. For private installations we have introduced a mechanical cut-out, which enables the circuit to be re-made by any person. It consists of a lever, on which is mounted two prongs dipping into mercury cups, and held in position by a spiral spring which resists the attraction of an electro-magnet on its armature when only the normal current is passing. When from any cause the current exceeds the amount to which the cut-out is adjusted by, say, 40 per cent., the electro-magnet attracts its armature, and the prongs being released fly out of the mercury cups and thus break the circuit. All that is necessary for the restoration of the circuit is that the box be opened thus [Experiment shown], and the prongs re-inserted by pulling down the lever when light is restored. But all necessity for such systems of cut-out and safety fuse may be avoided by care and judgment in wiring houses. The main points to be considered in laying on a supply of electricity to houses are as follows:—Where long distances are to be traversed, the wire shall not be small enough to have any appreciable effect on the electromotive force when the maximum current is passing. That the shortest route possible be the route taken, and that no wires be taken along or across metal surfaces or near any heated flues or hot-water pipes. Switches should be covered so as to exclude dust. There are a variety of dust-proof switches made, and for rooms requiring up to three lights we recommend the small switches now shown in action. When a person enters a room after dark it is an easy matter to push or pull this little knob, which may be fitted near the door, and on leaving the room the same action will put out the light and thus economise the current. Other forms of switches have their advantages, such as the B.T.K. switch, which it is impossible to turn in the wrong direction, and which cannot be left half on or off; this switch is suited for a number of lamps from 3 to 10 or 12. Then we have the Consolidated lever switch, which acts and wears well and is strong and substantial. In regard to fittings, it is a mistake to cluster the lamps together and to mount them in the heavy fittings which have been designed for gas. We recommend that lamps be suspended from the conducting wires, neatly twisted and terminating in such a mount as the holder in use on this platform. This method gives an airy appearance to the light, and also avoids the danger of short-circuit through drawing wires into metal tubes. The advantage of the form of lamp holder shown is that no part of the conducting circuit is exposed or uninsulated, and so there can never be any danger in consequence of any metal resting on the lamp or holder. Of incandescent lamps there are many varieties and makers, all of which succeed very well in making a globe and filament. But the aim should be to produce a lamp which is at once durable and economical in its consumption of energy. The lamps manufactured by the Consolidated Company are designed to fulfil both these conditions. The 140 candle-power lamps for street lighting, as shown, takes 60 volts and about 4 amperes, giving about 434 candles to the horse-power.

NOTES.

BELGIUM.—The new Minister of Posts, Railways, and Telegraphs for Belgium is M. Van den Peereboom.

CHICAGO.—The Central Union Telephone Company's new offices in Chicago are to be lighted by the Edison system.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 13th inst. were £2,485.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 13th inst. amounted to £3,139.

THE TELEGRAPH IN CENTRAL ASIA.—A Reuter's telegram dated St. Petersburg, June 16, says telegraphic communication is in course of construction between Merv and Askabad.

NEW ZEALAND.—According to the New Zealand papers a sharp shock of earthquake has been felt at Opotiki, and shocks have also been experienced in the north-eastern parts of the island.

OUTPUT OF BELL TELEPHONES.—The output of telephones for the month ended May 20 was 5,023, against 6,763 in 1883, making a total of 12,758 for the three months of the fiscal year, against 18,844 in like months last year.

AWARD.—The Council of the London Mathematical Society have awarded the first "De Morgan Memorial Medal" to Professor Cayley, F.R.S., for (besides other reasons) his important contributions to the Modern Higher Algebra.

ELECTRIC LIGHTING FOR LIGHTHOUSES.—The Trinity House are inviting tenders for the erection of new dwellings and additional buildings in connection with the installation of the electric light at St. Catharine's Lighthouse, Isle of Wight.

PROTECTION OF SUBMARINE CABLES.—The French Senate on Wednesday, the 14th March, ratified the Convention signed in Paris for the international protection of submarine cables. A translation of this Convention was given in our issue of the 17th May.

SHIP LIGHTING.—An American contemporary says the Bernstein Electric Light Company of Boston, Mass., has fitted its system on a coasting sailing vessel, using the steam power applied to the hoisting apparatus. About fifty lamps are used, including signal lights in the rigging.

SIXPENNY TELEGRAMS IN AUSTRALIA.—It is understood, says the *Colonies and India*, that Mr. W. J. Trickett, Postmaster-General, New South Wales, is about to recommend to the Executive that a sixpenny telegraph rate be extended to all the places enjoying the penny postage.

NEW BOOK.—We have received a copy of the second edition of Mr. A. Bromley Holmes's work on "Practical Electric Lighting," published by Messrs. Spon, of Charing-cross, S.W. Several additions have been made in the new edition, and a chapter has been added on "Secondary Generators."

RAILWAY COLLISION IN AMERICA.—A collision which occurred on the 14th inst. between an excursion train from Camden and an ordinary train from Atlantic City, on the Camden and Atlantic Railway, New Jersey, by which several people lost their lives, is attributed to the negligence of a telegraph operator on that line.

PROPOSED ELECTRICAL CONFERENCE AT PHILADELPHIA.—The Bill authorising the President of the United States to call a national conference of electricians to meet in Philadelphia this autumn has been reported on favourably by the Committee on Commerce, and referred again to the House Committee on Appropriations. The sum asked for is 25,000dols.

ELECTRIC LIGHTING IN AMERICA.—The Detroit, Mich., Board of Aldermen has contracted with the Brush Electric Light Company to light the entire city, from July 1, 1884, to July 1, 1885, with seventy-two light towers, having 300 lamps of 2,000 candle-power each, for 95,000dols. The company erect and maintain the poles, wires, towers, &c.—*Sanitary Engineer.*

ELECTRIC LIGHTING ON THE EMBANKMENT.—The Metropolitan Board of Works have received tenders for lighting the Embankment for three years from the Hammond Electric Lighting Company, Mr. H. E. Edmunds, Messrs. Woodhouse and Rawson, and Mr. Lever. They have been referred to the Works and General Purposes Committee for consideration and report.

THE TELEPHONE IN HOLLAND.—On the first of last month the Netherlands Bell Telephone Company had the following subscribers to its system :—In Amsterdam 1,093, Rotterdam 508, Arnhem 127, The Hague 190, Groningen 72, Utrecht 68, Haarlem 57, Zaandam 14, and Dordrecht 58, or a total of 2,187, of which 1,992 were at that time connected with the various exchanges.

PROVISIONAL ORDER GRANTED.—The Board of Trade has granted a provisional order to the West Middlesex Electric Lighting Company authorising them to supply electricity for the lighting of the district comprised within the area of the Fulham District Board of Works. The order requires the company to set aside £16,000 of their capital to be appropriated for the purposes of the order.

ELECTRIC LIGHTING IN MILLS.—The electric light has been introduced into the woollen mills of Mr. James Clay, at Luddenden Foot, Yorkshire. A Crompton-Bürgin compound self-regulating dynamo supplies current for thirty-six Swan 20 candle-power lamps, which are placed in the carding and spinning rooms, weaving department, &c. The installation has been effected by Mr. Wilson Hartnell, of Leeds.

OVERHEAD WIRES.—Judgment has been given in the case of the Wandsworth Board of Works *v.* The United Telephone Company, in which the company appealed against a recent decision of Mr. Justice Stephen, and the company have gained their case. The Board wished to restrain the company from erecting overhead wires, on the ground that the company committed a trespass on their property in erecting such wires. A report of the case will be found in another column.

FRESNEL.—The Duc de Broglie, mayor of the Commune de Broglie, and President of the Société d' Agriculture, Sciences, Arts et Belles Lettres de Bernay, has, says the *Ville de Paris*, invited the Académie des Sciences to send representatives on the 14th September next to be present at the inauguration of a monument which will be raised in the Commune de Broglie to the memory of Augustin Jean Fresnel, the illustrious physicist, who was born in 1788, and died at Paris in 1827, aged 40.

THE ROYAL SOCIETY.—The following were elected Fellows of the Royal Society at the annual meeting, held last week, at Burlington House, viz.: Professor G. J. Allman, LL.D., Professor J. B. Balfour, Joseph Baxendell, F.R.A.S, Professor A. S. Herschell, M.A., Wilfred H. Hudleston, M.A., Professor Horace Lamb, M.A., Professor John G. M'Kendrick, LL.D., M.D., Arthur Ransome, M.D., Professor Charles S. Roy, M.D.,

Digitized by Google

Professor Arthur W. Rücker, M.A., Joseph J. Thomson, B.A., Lieutenant-Colonel Charles Warren, C.M.G., and Professor Morrison Watson, M.D.

THE TELEPHONE IN THE WEST INDIES.—According to a statement made by the manager of the Tropical American Telephone Company, the exchange in Port of Spain has now upwards of 130 subscribers, and it has been arranged to open a trunk line between San Fernando and the capital. Notwithstanding its limited population, about twenty subscribers have already been obtained for the branch exchange it is proposed to open in San Fernando, and from thirty to forty estates in the colony have intimated their readiness to enter the system as soon as the lines can be extended to permit of their doing so.

THE VIENNA STADTTHEATER.—Herr Bukowics, the manager of this theatre, which our readers will remember was burned some time ago, and several *employés* were charged in the police-court at Vienna on Monday last with neglect of duty. We select an item of the evidence as affording food for reflection. It was stated that the fireman in charge of the theatre on the day of the catastrophe, on being informed as he sat in his lodge reading the newspaper that the building was on fire, took a cab and drove to the Central Fire-station, instead of using the telegraph to transmit the news. Hence arose a delay which had the most momentous consequences.

SMALL ARC LAMPS.—Messrs. Siemens Brothers and Co., of Berlin, have recently constructed some small arc lamps which will work in parallel, and do not require more than two amperes of current and an E.M.F. of 40 volts. The upper carbon descends by its own weight, and passes as it is consumed through a hole pierced in a copper disc, the diameter of which is slightly smaller than that of the carbon. The lower carbon is pushed upwards by the action of a spring in a copper tube. A solenoid regulates the length of the arc by its action on a core, to which the upper carbon is attached. The idea is to employ these instead of incandescent lamps, the arc lamps being more economical.

ELECTRIC HOUSE BELLS.—To give our readers some idea of the rapid progress now being made with electric bells for houses in this country we may mention that a contract has been completed for the fitting up of the whole of the Richmond House Estate, comprising no less than 286 houses, with the telegraph bells and indicators of Messrs. Francis and Co., Eagle Telegraph Works, Hatton Garden. This firm, we learn, are also busily engaged in the manufacture of stores for a similar undertaking in Sweden, thus showing that for all ordinary communications, particularly as applied to our homes, this system holds recognised advantages, and it seems that now scarcely any new property is considered complete without these improved and necessary conveniences.

THUNDERSTORM IN FRANCE.—On Sunday last, says a French paper, a heavy thunderstorm occurred between 4 and 6 p.m. at Chatellerault. Telegraphic communication was interrupted for more than two hours, and several buildings were struck. Amongst others a rifle manufactory was struck, although it had several lightning conductors. "This must have been," says our contemporary, "the effect of a return shock." On the previous Friday the lightning struck the semaphore station at Cape Sagro, near Bastia. After having fused the telegraph wires, broken the lightning protector and galvanometer, and spoilt the barometer, the current smashed the window panes to powder. The inmates of the station received some slight wounds, but were otherwise unhurt.

ELECTRIC LIGHTING IN BARROW-IN-FURNESS.—The Criterion Restaurant, Cornwallis-street, Barrow, which has just been opened by Messrs. Case and Co., is lighted throughout by Swan incandescent lamps. The dynamo used is known as the Phœnix, and it is, we believe, identical with what was once called the "Lumley." It is driven by a Robey engine. A switch-board in the dynamo room gives complete control over the lights, and is fitted with one of Andersen's safety cut-outs, which we illustrated and described in our articles on the Vienna Exhibition. The whole of the material has been supplied and the installation carried out by Messrs. Menzies and M'Whirter, electrical engineers, of Glasgow. The volt and ampere meters used in this installation are the invention of Mr. M'Whirter.

A SEWER DAMAGED BY LIGHTNING.—In the course of a thunderstorm which passed over Wigan, in Lancashire, on Saturday week, a day of considerable electrical disturbance throughout the country, as we mentioned in last week's "Notes," a sewer near the town was struck by lightning. A local paper gives the following particulars:—"About half a mile below Dean Lock, below Gathurst, however, the electric fluid appears to have played a very peculiar freak. After striking and completely demolishing a large willow tree it ran along the ground for a distance of about nine feet, then darting downwards it tore up the earth, making a large fissure, and ripped off a piece of the iron outfall sewer piping 6ft. long and 15in. wide, embedding it in the earth out of sight. The pipe, which is 27in. in diameter, is five feet below the surface of the ground."

AN ELECTRIC LARYNGOSCOPE.—Dr. Carl Seller, of Philadelphia, has devised an electric laryngoscope for illuminating the stomach and throat. It consists of an ordinary head mirror, which has attached to its lower rim a bar about four inches long. An incandescent lamp of six candle-power is mounted on the end of the bar, and between it and the reflector is a simple bi-convex lens of short focus, to converge the rays of light on the reflector. On the side of the lamp, away from the reflector, is a shield of silvered mica to protect the patient's face from direct light. The conducting wires run from the lamp to the head-band, to which the reflector is joined by a ball and socket joint, and thence to the battery. Thus the examiner is not dependent on any stationary light; when the mirror is adjusted light is always thrown in the direction of the axes of the eyes.—*Electrical World.*

THE MAGNETIC POLARITY OF IRON.—Captain John Hayden, of Bath, Me., author of "The Requisite Nautical Assistant," writes to the *Scientific American* stating that as long as forty years ago he practically tested, on shipboard, the influence of upright iron bars or masses of iron on the needle. He says: "Iron rods or bars, in a horizontal position, exert but little force on the compass, but the same amount and form of iron placed vertically produce an immense effect on the needle. The iron rod immediately becomes magnetic when placed in a vertical position, its magnetism increasing with the length of time it so remains, although it manifests no magnetism when parallel with the horizon. This effect on iron is most marked when the rod is held or placed in the magnetic meridian, and in the direction of the tipping needle, which is in this country with the bottom end swung to the north about thirty degrees from the perpendicular."

TELEGRAPHIC NEWS TO CLUBS.—In the House of Commons on Monday last, Mr. Fawcett said, in answer to Mr. Houldsworth, that the practice prevailed in certain towns of sending racing news to clubs and then transmitting it by telephone to other clubs and to certain persons. This was regarded as an abuse of the privilege which allowed news to

Digitized by Google

be sent at a considerably lower rate by telegraph to clubs than was charged to the ordinary public. Steps had been taken to put an end to the practice. On Tuesday the same hon. member asked a further question, to which Mr. Fawcett replied that news is supplied at press rates to clubs registered at the General Post Office, on condition that such news is used solely for exhibition in the club rooms. The systematic communication of such news to persons other than members of the club, whether the communication be by telephone or otherwise, is held by the Department to be an abuse of the privilege.

THE TELEPHONE IN BRAZIL.—Summarising the annual report of the Companhia de Telegraphos Urbanos, of Rio de Janiero, the *Anglo-Brazilian Times* says :—"Unfortunately, the Companhia Nacional de Electricidade, of which the other company is a licensee, has not been able to induce the telegraph department to permit of telephone communication between Rio and Petropolis. The company had on the 31st March 776 lines working, viz., 627 in Rio, 95 at S. Paulo, 33 at Petropolis, and 21 at Nitherohy, and applications were on file for 601 more. In March the Rio lines alone transmitted 113,424 calls, equal to over 1,350,000 a year. In January the telegraph department exacted that the putting up of all new lines should be effected only by that department, and in consequence the work was transferred to the department, giving rise to delays in attending to new applications. The company has in stock 250 telephones, 10,000 kilograms of galvanised wire, &c., of the value of 32,000dols., and has ordered from England 4,000 metres of insulated air cable having seven wires."

THE GERARD INCANDESCENT LAMP.—M. Gallice writes to *L'Electricien* as follows :—"We have observed something in the Gérard lamp which seems to deserve attention. One of these lamps of 50 candle-power, fed by a one horse-power De Meritens machine, gave a light of about 80 candles. At certain times a violet coloured glow, exactly like that of a Geissler tube, with rarefied air, occupied the lower part of the lamp, at the point where the carbon and platinum wires are soldered together. When a magnetised bar was brought near to the lamp this glow became a kind of flaming ring at the soldering point. Another lamp of the same type, but having less resistance, when run up to nearly 200 candle-power showed the same phenomenon in a still more striking manner. The whole of the glass bulb was occupied by the violet glow. Without knowing the cause of this curious effect, we think it due to the extreme rarefication of the air in these lamps. This fact shows that under certain circumstances the same effects can be obtained with a weak electromotive force not exceeding 50 volts, as with the induced currents of the Ruhmkorff coil. We have not been able to obtain these effects in the lamps of Swan or Nothomb, which we have by us."

METEOROLOGY IN ITALY.—The number of meteorological stations in Italy is 223, of which 92 belong to the Government and 131 to the Meteorological Society. The society of which Father Denza is president furnishes, moreover, a portion of the apparatus to 60 out of the 92 Government stations. These 92 stations send their daily reports by telegraph to the central office in Rome, which should receive them at 7 a.m., local time. The Rome office summarises their contents, and despatches them to the central offices of all nations connected with the international service, and receives in exchange the same information from Russia, Sweden, Norway, Germany, Austria, Belgium, Holland, Switzerland, France, Turkey, England, and Spain. In all fourteen messages are sent and fourteen received. As each country does the same, the number of international messages circulating ea ch morning is 196. If a central international office was established at Berne, for instance, where there is already a central postal and telegraph office, it would be sufficient if 14 messages were despatched and 14 received, or 28 messages would do for the whole service. The managers of the meteorological stations are either astronomers, university professors, sailors, engineers, telegraph *employés*, or amateurs with a taste for science.—M. de Fonvielle, in the *Ville de Paris*.

ELECTRIC LIGHTING AT HULL.—The opponents of electric lighting on the Hull Town Council very nearly succeeded in terminating Messrs. Siemens' contract for supplying certain arc lamps in that town a few days since. One of the members of the council at their last meeting moved as an amendment to the resolution confirming the minutes of the lighting committee, which minutes recommended the continuance of the electric lamps, "That the contract with Messrs. Siemens, terminating on the 28th of July, be not renewed." He stated that the cost of 26 electric lamps from March, 1883, to March, 1884, was £1,824 8s. 11d., which, together with 39 gas lamps, costing £250 3s., made a total of £2,074 11s. 11d. as the cost of the electric light. They formerly paid the gas company for lighting the whole of the old town £1,074 11s. 7d., and he argued that, if they merely wanted to improve the old town, they could provide improved gas lamps for another £1,095. The amendment was seconded by Mr. Shaw.—Mr. Elam (chairman of the Lighting Committee) pointed out that the electric light had enabled the town to get a reduction in the price of gas both for street lighting and domestic purposes. He asked the council to support the committee in continuing their endeavours to protect the town and its interests in that respect.—The amendment on being put was lost.—On a division, the result of the voting was :—For the amendment, 20; against, 21.—Mr. Pool gave notice that, at the next meeting of the council, he would move the amendment as a resolution.

THE BENTON IRON CELL.—In his report on "Submarine Mines," Col. Abbot, of the United States Corps of Engineers, writes as follows of the Benton iron cell :—"A battery capable of occasionally supplying a moderately strong current, and which can be left standing without the destructive local action inherent in every form of the nitric acid cell, is sometimes useful, and Colonel Benton has devised the following pattern to meet this end. The jar is of cast iron, 6½in. in diameter, and 6½in. deep. The positive plate, also of cast iron and cylindrical in form, exposes 140 square inches to the surrounding fluid, which consists of a saturated solution of sodium chloride (1lb. to 4⅝lb. of water). The negative plate consists of a carbon slab, ·8 by 2 by 9in. long, immersed 7in. in a porous cup of white earthenware filled with the following mixture :—6oz. of peroxide of manganese, 6oz. of broken carbon, 8oz. of water, 5¼oz. of sulphuric acid, and 1½oz. of a saturated solution of potassium bichromate in nitric acid. The surface of the carbon plate exposed to the fluid is 40 square inches. The internal resistance of this cell, when fresh, is ·18 ohm; but it rapidly increases after the circuit is closed. The electromotive force is about 1·5 volt. The peculiarity of the cell appears to be the rapid increase of internal resistance. A solid deposit begins to form at the bottom of the jar and in the pores of the porous cup shortly after the closing of the circuit, and it appears to increase while the work continues. This is the worst feature of the combination, since it involves frequently washing the porous cup in dilute muriatic acid to prevent the steady increase of

Digitized by Google

internal resistance. When only occasional work is required this difficulty is less troublesome, as there is an evident tendency to re-dissolve during intervals of rest."

A Photometrical Standard.—The Gas Institute some time since appointed a committee to report upon a standard of light for photometrical purposes. Their report was presented at the annual meeting of the Institute held last week. From this it appears that the committee resolved that, as any standard having a wick as one of its component parts cannot be relied upon to give unvarying results, the sperm candle only (being the present standard in this country) should be tested as representing this class; and that the other suggested standards to be tested should be—the Methven screen, the Harcourt air-gas, the Harcourt air-gas lamp, the Giroud *vérificateur*, and the Giroud relative standard. The deductions to be drawn from the report are—That candles of different makers, all complying with the parliamentary definition, give very discordant results. That candles from the same maker vary in the results they give, though to a less extent; and that therefore the candle is not reliable as a standard. That the Harcourt standards are not convenient, or suited for use in general photometry, as they demand too much attention from the operator. That the Giroud standards "are not exact enough to be adopted as absolute standards." That the amount of light passing through the slot of a Methven screen from an Argand burner in which gas varying from 14 to 22 candles illuminating power is consumed, and from gas of any quality when carburetted in a defined manner, is practically invariable, and may therefore be relied upon at all times, and under all circumstances be of equal value and give out the same amount of light. The committee add that if it be thought objectionable to use coal gas as a means of producing the standard light, Harcourt's air-gas, or even air carburetted with highly-rectified petroleum, may be used, as they have ascertained that they both give reliable results with properly proportioned Methven slots. The report is to be published as an appendix to the *Transactions* of the Institute for this year.

The Life of a Ten-candle Lamp.—Herr Zacharias has made some experiments on the life of incandescent lamps, which he has published in the *Zeitschrift für Electrotechnik*. He found that a lamp of 10 candle-power (normal) would last for the undermentioned number of hours when giving the different candle-powers mentioned below:—

Candles.	Hours.	Candles.	Hours.
10	5,550	19	534
11	3,963	20	443
12	2,857	21	371
13	2,134	22	312
14	1,628	23	266
15	1,292	24	228
16	1,000	25	196
17	802	30	163
18	651		

The life of an eight candle-power lamp (normal) he found to be as follows:—

Candles.	Hours.	Candles.	Hours.
8	2,260	15	233
9	1,470	16	179
10	1,000	17	145
11	714	18	118
12	512	19	96
13	385	20	80
14	290		

The duration of the lamp is therefore a relative quantity, and depends upon the current which is supplied to it. Now it is manufactories which make great use of the electric light, and in the greater portion of them to raise or lower the elastic power of the steam by one to half an atmosphere is to proportionally vary the power of the motor, and consequently the current furnished by the dynamo. Why not employ a voltmeter for the engine driver to consult? The utility of this apparatus is shown by the following example:—Herr Zacharias had occasion to install electric lamps in a paper mill and another works under exactly similar conditions, viz., same machines and the same mounting and fittings. The only difference was in the motor and the engineer. The works were supplied with power by an old single-cylinder engine, which worked most irregularly, whilst the other had a three-cylinder engine; but the engineer of the former was constantly looking after the working of his apparatus. He had a voltmeter and a variable resistance at his disposal, which enabled him to take care that the E.M.F. remained uniform at 98 volts. Now, half the lamps at the works (each requiring 50 volts) lasted for 2,800 hours, whilst in the paper mill, the installation in which was completed several weeks later than the other, a large number of lamps had to be renewed within a short time.

Telephonic Communication.—In the House of Commons on Thursday, the 12th instant, Mr. Fawcett was asked several questions on this subject. We take the following report of what occurred from *The Times*. In the first instance, Mr. Whitley asked the Postmaster-General whether he was aware that the Post Office had refused to allow the same advantages of telephonic inter-communication to Liverpool and Birkenhead, which are divided by the River Mersey, as are allowed to Manchester and Salford, which are divided by the River Irwell; and whether he was prepared to reconsider the application of the Lancashire and Cheshire Telephone Company to establish communication between the two licensed areas, so as to give the people of Liverpool and Birkenhead the facilities which are enjoyed by Manchester and Salford.—To this Mr. Fawcett was understood to reply that Salford and Manchester were served as one town for postal and telephonic purposes. The same connection did not exist between Liverpool and Birkenhead, which had each a separate telephonic and postal system. He regretted, therefore, that he could not accede to the request of the hon. member, but he thought that telephonic communication between Liverpool and Birkenhead should be by trunk wire, the same as between Liverpool and other towns. Mr. Whitley asked whether that would not be very expensive. Mr. Fawcett said it would, no doubt, be more expensive.—Mr. Briggs then asked whether Mr. Fawcett was aware that the Lancashire and Cheshire Telephone Company were desirous to open call offices in the various towns in their district, whereby for a small payment the public might converse with subscribers to the Telephone Exchange; whether the Postmaster-General insisted upon the company charging 1s. each time such facility was afforded, and whether he could see his way to relax these terms.—Mr. Fawcett answered that the subject of this question had been for some time under careful consideration, and he regretted that he was unable to sanction any smaller charge than 1s., the minimum amount now charged for an inland telegraph message.—Mr. Jacob Bright asked the Postmaster-General whether by letter dated April 18, 1883, addressed to the Lancashire and Cheshire Telephone Company, the Post Office consented to erect and maintain wires for telephonic communication between town and town for a guaranteed payment of £10 per mile per annum; and if, in such letter, the company were to be allowed to obtain as many subscribers

Digitized by Google

as they could for each wire, and to charge whatever annual rate they chose, so long as no favour or preference was shown —that is to say, so long as precisely the same rate was charged to every subscriber for the same use of a wire; whether, when the company accepted the conditions and announced their intention of bearing the entire cost themselves and giving the advantages to the subscribers, free of charge, the Department refused its assent to such an arrangement, and ultimately insisted upon the company charging a minimum annual rental of 10s. per mile of distance between town and town, or, if the subscription was monthly, a minimum charge of 18s. per mile per annum; whether he was aware that, in the opinion of the company, these rates were practically prohibitive, and whether he would consider the advisability of so modifying them as to give to the people of Lancashire and Cheshire the advantages which the company are ready and willing to offer them, of being able to converse between town and town of the district on reasonable terms.—Mr. Fawcett in reply said that he could not, without unduly encroaching on the time of the House, explain all the details of the correspondence which had taken place, but would be glad to show it to any hon. member who would call at the Post Office. He did not think he would be justified in making any modification in the terms to which the Department had agreed with regard to trunk wires.

Earth Currents.—Mr. H. Wild has communicated the results of observations on earth currents made in the Observatory of Paulowsk, Russia, to the *Bulletin* of the St. Petersburg Academy of Sciences, and we extract the following from a translation of his article which appears in the supplementary number of the *Phil. Mag.* for this month:—"Thanks to the kindness of the Directorate of Russian Telegraphy, the Meteorological and Magnetic Observatory of Paulowsk has already, since the month of August, 1882, been in possession of two submarine lines, each a kilometre in length, one being perpendicular and the other parallel to the magnetic meridian. Each of these lines is connected with an aperiodic galvanometer set up in the underground pavilion for observing magnetic variations; so that the readings of the scale may be made at the same time as those of the variation instruments." . . . .

"The calculation of the observations made regularly during the period from September, 1882, to September, 1883, has been so far advanced as to enable me to communicate to the Academy some interesting results which I have deduced from them:—(1.) The earth current at Paulowsk in our lines of *one* kilometre in length is usually manifested not as a current which flows for some time in a certain direction, and the force of which varies slowly, but as more or less strong alternating currents, which change rather rapidly their direction in space. (2.) The component of the earth current which appears in the E.-W. line is generally stronger than that observed in the N.-S. line; the direction approaches therefore the parallels rather than the meridians. (3.) The observations of the term-days, taken separately each day, do not show a daily course of the earth current either in respect of magnitude or number of oscillations. But taking the mean of 24 term-days, a sufficiently distinct, though small, daily course is seen. The current in the S.-N. line indicates a maximum between 4 and 5 o'clock in the morning, and a minimum at 8 o'clock in the evening; and the current in the W.-E. line a maximum at 8 a.m., and a minimum at 1 p.m. The amplitude of this oscillation is very small, only corresponding for the two components to about 0·0008 volt. This variation does not coincide with the normal variation of the magnetic elements; and it follows that the daily variation of the earth currents cannot be regarded as the origin of the daily variation of the magnetic elements. (4.) As soon as the earth current shows itself in the two lines with greater force, the magnetic instruments begin to diverge from their regular course; and these disturbances increase in general with the strength of the earth currents without there being any strict proportionality between the two classes of phenomena. On the 15th of November, 1882, for instance, the earth currents showed themselves in greater strength in the two lines than on the 1st of March, 1883; and nevertheless the course of the magnetic instrument on the first of these days was far more irregular than on this latter day. (5.) If, as Sir G. Airey has already done for similar observations at the Greenwich Observatory, we compare the current in the S.-N. line with the changes in the declination, and the current in the W.-E. line with the changes in horizontal intensity, we often find, especially for somewhat slow changes, perfect equality between these two kinds of disturbances; but the variation of the current always precedes that of the earth's magnetism by at least five minutes, so that the current appears as the primary cause of this latter. Thus the motion of the magnetic apparatus is always that which would be required by the fundamental law of electro-magnetism, if the earth current had a direct influence on the magnets. If, for instance, a positive current from north to south shows itself in the N.-S. line, the easterly declination of the needle increases at the same time; and if in the E.-W. line a positive current goes from east to west, the horizontal intensity of terrestrial magnetism becomes greater—that is to say, the north pole of the bifilar moves towards the north. The retardation which the indications of the magnetic instruments experience relatively to those of the galvanometer could be explained by the hypothesis that the earth current, which directly influences the magnets of the galvanometers, only acts on the variation instruments by the magnetisation of the more or less thick layers of earth, and this requires a certain time. (6.) This retardation in the effects of the earth current explains, partially at any rate, the want of strict proportionality between the variations of the current and the magnetic elements. It is observed that the proportionality fails particularly when the changes in the current are very frequent and alternating; and it is more complete on those days on which the disturbances are not sudden. Now it will be readily understood that in the former case the transitory currents in opposite directions which rapidly succeed each other will be partially destroyed by the magnetisation of the earth, so that the variations of the magnetic instruments will be relatively smaller. The observations of the 15th November, 1882, and of 1st March, 1883, as well as the curves registered by the magnetograph, support this explanation. The curves registered on the 1st of March show by the clearness of the lines a relatively tranquil course of the magnets, although the slow disturbances have been somewhat large; and, in consequence, the curves drawn from the readings of the galvanometers are not very marked, and those of the S.-N. current are very similar to the curves of the unifilar, while those of the E.-W. current are in close agreement with the registrations of the bifilar. On the other hand, the two kinds of curves of November 15 show little agreement with each other; and although the variations of the two currents are very great and very rapid, the registers of the magnetograph, as well as the direct observations of the magnetic instruments, do not show great perturbations; but if we examine more closely the curves registered, we easily observe the traces of a permanent oscillation of magnets within small limits. *We may then conclude that earth currents are always the primary cause of magnetic storms, but not of the periodical variations of the magnetic elements.*"

ELECTRO-CHEMISTRY.—Inorganic.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 103.)

Magnesium is a very highly electro-positive metal; it deposits in the metallic state nearly all the base and noble metals from solutions of their salts by simple contact. According to Roussin, it deposits bismuth, platinum, gold, silver, mercury, copper, lead, thallium, tin, and cadmium (*Chem. News*, Vol. XIV., p. 27). In addition to these, according to Phipson, it deposits nickel, cobalt, and zinc, and even iron and manganese, from solutions of ferrous and manganous salts; but it does not deposit aluminium from its solutions (Watts's "Dictionary of Chemistry," Vol. V., p. 795).

A sub-oxide of magnesium appears to be formed when sodic or ammonic chloride is electrolysed with electrodes of magnesium wire, the anode being covered with the black oxide (W. Beetz, Watts's "Dictionary of Chemistry," Vol. VI., p. 796). I have obtained this compound in a great variety of liquids by immersing magnesium in contact with platinum or palladium in them; solutions of chloride and bromide of potassium or sodium were some of the most suitable liquids (*Proceedings* Birmingham Philosophical Society, Vol. IV., Part I.).

The metal is deposited by means of a separate current. According to Bertrand, an adherent deposit of the metal may be obtained by electrolysing during a few minutes a concentrated aqueous solution of the double chloride of magnesium and ammonium by means of a very powerful current and a cathode of copper (*Chem. News*, Vol. XXXIV., p. 227; *Jour. Chem. Soc.*, 1877, Part I., p. 161). Bunsen obtained it by electrolysing fused chloride of magnesium at a red heat in a deep and covered porcelain crucible which was divided by a vertical partition of porous porcelain extending from the top to half way down the vessel. The current employed was from ten zinc and carbon elements. The electrodes were of carbon and were introduced through openings in the cover, and the cathode was notched, so that the light melted metal collected in the notches, instead of rising to the surface and then burning. Matthiessen states that the metal may be much more easily obtained by this method if the salt employed consists of a mixture of four molecules of magnesic chloride, three of chloride of potassium, and a little chloride of ammonium. In this case, the liquid salt being lighter than the magnesium, the latter falls to the bottom (Watts's "Dictionary of Chemistry," Vol. II., p. 438; Vol. III., p. 751).

For the use of electrolysis in the metallurgy of magnesium see F. Fischer, *Jour. Chem. Soc.*, Vol. XLIV., 1883, p. 399.

Separation of Thorium.—Atomic weight = 233·9. Sodium sets free metallic thorium from fused double chloride of thorium and potassium in an iron crucible (L. F. Nilson, *Jour. Chem. Soc.*, Vol. XLIV., 1883, p. 152).

Separation of Norwegium.—Atomic weight = 145·9 (?). According to Dr. Tellef, the sulphate solution of this metal is turned brown on the addition of zinc, and the metal is deposited in the pulverulent state (*Chem. News*, Vol. XL., p. 25).

Separation of Cerium. Ce. Atomic weight = 94·2. **Lanthanum.** La. Atomic weight = 92, and **Didymium.** Dy. Atomic weight = 96.—Crude double chloride of cerium and potassium in a fused state at a red heat is decomposed by metallic sodium, and metallic globules of impure cerium, together with shining scales of an oxychloride of cerium, are obtained (Wöhler, Watts's "Dictionary of Chemistry," Vol. VI., p. 419).

When a mixture of oxide of cerium and potassic fluoride is melted in a porcelain crucible, and subjected to electrolysis, potassium and silicide of cerium in the form of a brown mass are deposited upon the cathode (Ulik, Watts's "Dictionary of Chemistry," Vol. V., p. 266; and Vol. VI., p. 420).

According to Bunsen either of these metals may be separated by electrolysis with a separate current in the following manner:—Its chloride is mixed with sal-ammoniac (both as dry as possible), and the mixture heated to redness in a platinum crucible to expel all the sal-ammoniac. A porous clay vessel of the best quality is filled with the residue, then placed in a Hessian crucible, surrounded by a cylinder of sheet iron (with a long projecting strip for connection) to serve as the anode, and the space between the two vessels filled with a previously melted mixture of an equal number of equivalents of the chlorides of potassium and sodium. A thick iron wire, enclosed in a clay pipe, has a coil of very fine iron wire at its extremity to serve as the cathode, and is immersed in the fused salt in the inner vessel. The fusion is effected by preference in a fire of glowing charcoal, to prevent as far as possible the presence of aqueous vapour, and a strong current is employed (*Electrical News*, Vol. I., p. 184; *see* also Hillebrand and Norton, Watts's "Dictionary of Chemistry," Vol. VIII., pp. 420-421).

T. Schuchardt states that he has succeeded in obtaining by electrolysis metallic cerium in globules weighing from four to five grammes; and that he has also by the same process, with the aid of a current from six Bunsen's cells, obtained metallic didymium in globules the size of a pea (*Chem. News*, Vol. XL., p. 35). Hillebrand and Norton also state that they have obtained each of these metals by means of electrolysis (*Jour. Chem. Soc.*, 1876, Part II., p. 276).

According to C. Erk, the electrolysis of a neutral solution of cerous nitrate by means of a current from three Bunsen's cells yielded at the cathode a brownish-yellow mass and a quantity of ammonia sufficient to precipitate the whole of the cerium. A concentrated one of cerous chloride gave free chlorine at the anode and a deposit of ceroso-ceric hydrate at the cathode. The same salt in a state of fusion, with an anode of gas-carbon, gave small quantities of metallic cerium, and reddish white laminæ of cerium oxychloride at the cathode; and at the anode hydrochloric acid was evolved, and a large quantity of ceroso-ceric oxide formed. Strong solutions of cerous sulphate became yellow at the anode from formation of ceroso-ceric sulphate, and at the cathode yielded a little metallic cerium and a waxy deposit of ceroso-ceric sulphate, which subsequently became crystalline. An aqueous solution of cerous acetate yielded a basic acetate (Watts's "Dictionary of Chemistry," Vol. VII., p. 274).

Separation of Gallium.—Ga. Atomic weight = 69·86. Gallium is allied to aluminium and also to mercury. Cadmium separates gallium in the metallic state from a boiling solution of its chloride by prolonged immersion (M. Lecoq de Boisbaudran, *Jour. Chem. Soc.*, Vol. XLII., 1882, p. 897). So long as the liquids are sensibly acid, and the evolution of hydrogen goes on actively, zinc does not precipitate either the chloride or sulphate of gallium; but when the liquids become basic, and hydrogen is evolved but slowly, either the oxide or a subsalt of gallium separates in white flakes mixed with subsalts of zinc (M. Lecoq de Boisbaudran, *Chem. News*, Vol. XXXV., p. 158).

On passing a current from five bichromate cells through an ammoniacal solution of sulphate of gallium, with platinum electrodes, metallic gallium is deposited on the cathode, and a white film is formed upon the anode. In four and a half hours the metallic deposit weighed ·0016 gramme. With ten cells, in five hours it weighed ·0034 gramme. The metal was adhesive, not easily burnished by friction, but better by pressure (Lecoq de Boisbaudran, *Jour. Chem. Soc.*, 1876, Part I., p. 521; *Chem. News*, Vol. XXXV., p. 150).

According to Schicht, by electrolysis, gallium, like zinc, is deposited completely and in a pure state upon the cathode (*Chem. News*, Vol. XLI., p. 280.) By the electrolysis of a solution of oxide of gallium in one of caustic potash, by means of a current from five or six Bunsen's cells, and platinum electrodes, metallic gallium is deposited as liquid globules. (M. Lecoq de Boisbaudran, *Chem. News*, Vol. XXXV., pp. 150 and 168).

CORRESPONDENCE.

THE POTENTIAL AT POINTED PORTIONS OF A CHARGED CONDUCTOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the very interesting paper by Professor Tait on "Thunderstorms," published in your last issue, the author states:—"Since we are dealing mainly with *motion* of electricity, it is necessary to consider to what that motion is due. You all know that winds, *i.e.*, motions of the air, are due to differences of pressure. . . . Similarly the cause of the motion of heat in a body is difference of temperature. . . . Now, electricity presents a precisely analogous case. It moves in consequence of difference of *potential.* Potential, in fact, plays, with regard to electricity, a part precisely analogous to the *rôle* of pressure, or of temperature, in the case of motions of fluids and of conducted heat."

Further on the Professor says:—"On a very elongated body, terminating in a point, for instance, the electric density—that is the quantity per square inch of surface—may be exceedingly great at the point, while small everywhere else. Now, in proportion to the square of the electric density is the *outward pressure* of the electricity tending to escape by forcing a passage through the surrounding air."

The above would seem clearly to imply that pressure, or potential, is greater at pointed portions of a charged conductor than elsewhere—at a flattened portion, for instance. Can this be what the Professor intended to convey? The view that such is the case was at one time held by the late M. Du Moncel (vide *The Electrician* of April 12th, 1879). It is also, I believe, still held by many who accept the "law of the inverse squares of the distances" as a fundamental law of electrical attraction, and who have not realised that there is an electrostatic *circuit,* which is absolutely analogous to the conductive circuit.

As a matter of demonstrable fact, the pressure or the potential at the pointed portions of a charged conductor is always *less* than at its more flattened portions.—Yours, &c.,

DESMOND G. FITZGERALD.

PROFESSOR EWING AND THE COST OF ELECTRIC LIGHTING IN DUNDEE MILLS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Permit me to submit one or two remarks through the columns of your paper upon that portion of Professor Ewing's lecture, as reported in last week's issue, which deals with the question of cost of electric lighting in Dundee mills. There is no doubt but that the jute and linen mills in Dundee form a very large field in which electric lighting could be easily introduced, and give the best opportunities electric light companies could have. Some of these mills alone use over 6,000 lights, and the majority of them have plenty of engine power available to drive the machines.

Within the last two years it has been part of my duty to prepare estimates for mill lighting (amounting to a total of about 20,000 incandescent lamps) for different firms in this district, but not a single one of these resulted in an order, owing to the enormous cost of the plant, although I quoted the prices as low as could be done consistent with efficiency. In these estimates nothing was put in for engines or any other machinery—merely that of the dynamos, lamps, and wires; and in every case it was found that a very moderate percentage for interest and depreciation of the plant alone amounted to more than the annual gas bill, thus allowing nothing for the expense of fitting up the installation, or the renewal of lamps, coal, oil, attendance, &c.

I certainly should be delighted to find that Professor Ewing is right, but would be glad to know the details of his estimate in which he makes it appear that in the case of an installation of 500 20 candle-power lamps with the power supplied from existing engines the cost is almost the same as gas, including everything, such as the interest and depreciation, renewal of lamps, coal, oil, and attendance. The following are the details of one of my estimates for 500 incandescent lamps to light a public work in Dundee using 500 gas jets:—

	£	s.	d.
3 compound wound dynamos	£700	0	0
400 20 candle-power lamps, with holders, at 5s. 6d. each	120	0	0
120 10 candle-power lamps, with holders, at 5s. 6d. each	33	0	0
540 yards of 19 No. 12 cable	96	15	0
860 yards of 7 No. 14 cable	53	15	0
288 yards of 7-16 cable	10	4	0
162 yards of 7-14 cable	5	8	0
3,600 yards of small wire for single lamps	22	10	0
16 switches for circuits	8	0	0
1 main switch	5	0	0
6 switches for 14 to 26 lamps	1	1	0
16 fusible plugs for 20 candle-power lamps	4	0	0
6 fusible plugs for 10 candle-power lamps	0	18	0
	£1,060	11	0

Now, the cost of lighting with gas the same work for which this estimate was prepared is about £100 per annum, some years a pound or two more or less. The gas accounts were submitted to me for examination, and I know, therefore, that I was not deceived. You will thus see that to keep the electric light as cheap as gas you had only £100 per annum to meet interest, depreciation, renewal of lamps, coal, oil, and attendance, which it must be apparent to all is utterly inadequate.

I heartily endorse the professor's remarks as to the question of comfort and health of the workers, but I doubt if this is sufficient in itself to induce the Dundee manufacturers to go in for electric lighting if it is to cost more than gas.

In conclusion I may say that if the professor is right in his estimate, and I could find a company to supply the apparatus sufficiently cheap to keep the electric light about the same cost of gas, I have no fear I could do a very extensive business here.—Yours, &c.,

W. C. MARTIN.

Commercial-street, Dundee.

THE CRUTO LAMP—A DISCREPANCY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the table quoted (*The Electrician,* May 31st, p. 62), by M. A. Bandsept, the number of candles per horse-power in the case of the Cruto lamp is given as 103·58; whilst the corresponding number in the case of the Edison lamp is 144·88. But Mr. Bandsept says:—"If with these data before us we compare the economy of the Cruto lamp . . . with that of Edison, for instance, we find that the latter gives about twice the light for the same expenditure of energy." There is obviously here an error; perhaps Mr. Bandsept may be able to rectify it.—Yours, &c.,

HOLLOW CARBON.

TELPHERAGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In case any of your readers may be sufficiently interested in telpherage to give up a day to its inspection, will you allow me to state that the telpher line at Weston may be seen in action any day next week. The train will be kept running for the greater part of each day, so that no notice need be given by intending visitors; but in case of accident it might be well before starting to inquire at 12, Fitzroy-street, whether the train was running on that day. The line is in a field close to the village of Weston, and is reached by a drive of five or six miles from Stevenage or Hitchin. The drive from Stevenage is the shorter of the two. Visitors should inquire at the town farm for Mr. Brewtnall, who will give all necessary explanations.—Yours, &c.,

FLEEMING JENKIN.

Offices of the Telpherage Company,
53, Old Broad-street, E.C.

THUNDERSTORMS.

BY PROFESSOR TAIT, F.R.S.

(CONCLUDED FROM PAGE 117.)

"On September 3rd there was a great deal of streamers, which rose nearly from the same point that the thunder afterwards came from, and gradually worked north till they descended below the horizon. The air had a thunder-like appearance for several days before this storm; and for some nights after it the streamery vapour appeared equally diffused, muddy, inert, and languid, and not vibrating any variety of colours, as if the more volatile parts had been consumed. It is highly probable that lightning and the *aurora borealis* are of the same materials. In hot countries streamers are not seen, or but rarely, because they are kindled into thunder and flashes of lightning. In cold countries streamers abound, and it seldom thunders. The streamers have served to predict thunder to follow next day, in summer, and they have been also seen to break out into flashes of lightning. Thunder disturbs the motion of the magnetic needle, and it has been lately found in Sweden that streamers do the same. Thus thunder, electricity, magnetism, and the *aurora borealis* appear all wonderfully related; and many things remain undiscovered in this vast field, which is but just newly opened.

"As it is probable that the height which some philosophers have assigned for the streamers in the atmosphere is by several hundreds of miles too much, it were to be wished that people in various latitudes would carefully observe their altitude at different times of the night, that by comparing simultaneous observations this matter may be determined with more certainty."

At first reading one is inclined to regard this as a joke, but there is nothing whatever to justify the notion. That Dr. M'Fait was not killed on this occasion was certainly not due to any want of precautions on his part, well calculated to make such an event all but certain. He wanted only a knob on the blunt end of his short rod. Richmann, of St. Petersburg, had just before been killed while apparently in far less danger than Dr. M'Fait, and other incautious experimenters have since similarly suffered.

The destructive effects of lightning are familiar to all of you, so that I need not spend time in illustrating them on a puny scale by the help of Leyden jars.

All the more ordinary effects can thus easily be produced on a small scale. How small you may easily conceive when I tell you that a three-foot spark is considered a long one, even from our most powerful machines, while it is quite certain that lightning flashes often exceed a mile in length, and sometimes extend to four and five miles. One recorded observation, by a trustworthy observer, seems to imply a discharge over a total length of nearly ten miles.

When a tree is struck by a violent discharge it is usually split up laterally into mere fibres. A more moderate discharge may rupture the channels through which the sap flows, and thus the tree may be killed without suffering any apparent external damage. These results are usually assigned to the sudden vaporisation of moisture, and the idea is probably accurate, for it is easy to burst a very strong glass tube if we fill it with water and discharge a jar by means of two wires whose extremities are placed in the water at a short distance from one another. The tube bursts even if one end be left open, thus showing that the extreme suddenness of the explosion makes it act in all directions, and not solely in that of least resistance. When we think of the danger of leaving even a few drops of water in a mould into which melted iron is to be poured, we shall find no difficulty in thus accounting for the violent disruptive effects produced by lightning.

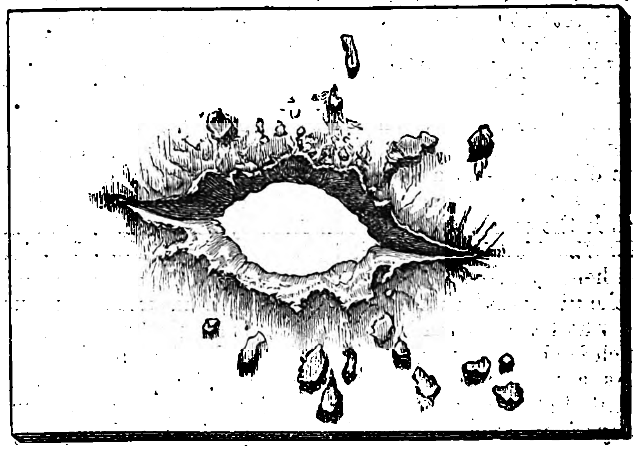
Heated air is found to conduct better than cold air, probably on account of the diminution of density only. Hence we can easily see how it is that animals are often killed in great numbers by a single discharge, as they crowd together in a storm, and a column of warm air rises from the group.

Inside a thundercloud the danger seems to be much less than outside. There are several instances on record of travellers having passed *through* clouds from which, both before and after their passage, fierce flashes were seen to escape. Many remarkable instances are to be found in Alpine travel, and specially in the reports of the officers engaged in the survey of the Pyrenees. Several times it is recorded that such violent thunderstorms were seen to form round the mountain on which they were encamped that the neighbouring inhabitants were surprised to see them return alive.

Before the use of lightning-rods on ships became general great damage was often done to them by lightning. The number of British ships of war thus wholly destroyed or much injured during the long wars towards the end of the last and the beginning of the present century is quite comparable with that of those lost or injured by gales, or even in battle. In some of these cases, however, the damage was only indirectly due to lightning, as the powder magazines were blown up. In the powder magazine of Brescia, in 1769, lightning set fire to over two million pounds of gunpowder, producing one of the most disastrous explosions on record.

A powerful discharge of lightning can fuse not only bell-wires, but even stout rods of iron. It often permanently magnetises steel, and in this way has been the cause of the loss of many a good ship; for the magnetism of the compass-needles has been sometimes destroyed, sometimes reversed, sometimes so altered that the compass pointed east and west. And by the magnetisation of their steel parts the chronometers have had their rates seriously altered. Thus two of the sailor's most important aids to navigation have been simultaneously rendered useless, or, what is worse, misleading; and this, too, at a time when, because of clouds, astronomical observations were generally impossible. All these dangers are now, however, easily and all but completely avoidable.

A very singular effect of lightning sometimes observed is the piercing of a hole in a conducting-plate of metal, such as the lead covering of a roof. In such a case it is invariably found that a good conductor well connected with the ground approaches near to the metal sheet at the part perforated. We can easily repeat the experiment on a small scale with tinfoil. [A thick piece of sheet lead from the lower buildings of Nelson's monument, Edinburgh, punctured by lightning, was exhibited. It is figured in the woodcut, reprinted (by permission) from *Proc.* R.S.E., 1863.]



Sheet-Lead Punctured by Lightning.

The name *thunderbolt*, which is still in use, even by good writers, seems to have been introduced in consequence of the singular effects produced when lightning strikes a sandhill or sandy soil. It bores a hole often many feet in length, which is found lined throughout with vitrified sand. The old notion was that an intensely hot, solid mass, whose path was the flash of lightning, had buried itself out of sight, melting the sand as it went down. It is quite possible that this notion may have been strengthened by the occasional observation of the fall of aerolites, which are sometimes found, in the holes they have made, still exceedingly hot. And at least many of the cases in which lightning is said to have been seen in a perfectly clear sky are to be explained in the same way. Everyone knows Horace's lines—

> "Diespiter
> Igni corusco nubila dividens
> Plerumque, per purum tonantes
> Egit equos volucremque currum."

But Virgil's remark is not so commonly known. He is speaking of prodigies of various kinds, and goes on:—

> "Non alias coelo ceciderunt plura sereno
> Fulgura; nec diri toties arsere cometae."

It is very singular that he should thus have associated comets and meteorites, which quite recent astronomical discovery has shown to have a common origin.

Another remarkable peculiarity, long ago observed, is the characteristic smell produced when lightning strikes a building or a ship. Thus, in the "Odyssey," Ulysses tells how his vessel suffered after the crew had killed the kine of Helios:—"In the same hour Zeus thundered, and cast his bolt upon the ship, and she reeled all over, and was filled with sulphur." This was, till comparatively recent times, the common belief; nowadays we know it to be mainly due to ozone. In fact, all the ready modes of forming ozone which are as yet at the disposal of the chemist depend upon applications of electricity. But besides ozone, which is formed from the oxygen of the air, there are often produced nitric acid, ammonia, and other compounds derived from the constituents of air and of aqueous

Digitized by Google

vapour. All these results can be produced on a small scale in the laboratory.

Hitherto I have been speaking of lightning discharges similar in kind to the ordinary electric spark, what is commonly called *forked* or *zigzag* lightning. Our nomenclature is very defective in this matter, and the same may be said of the chief modern European languages. For, as Arago remarks, by far the most common form of lightning flash observed in thunderstorms is what we have to particularise, for want of a better term, as *sheet lightning*. He asserts that it occurs thousand-fold as often as forked lightning; and that many people have never observed the latter form at all! It is not at all easy to conceive what can be the nature of sheet lightning, if it be not merely the lighting up of the clouds by a flash of forked lightning not directly visible to the spectator. That this is, at least in many cases, its origin is evident from the fact that its place of maximum brightness often takes the form of the *edge* of a cloud, and that the *same* cloud-edge is occasionally lit up several times in quick succession. You will remember that we are at present dealing with the appearances observed *in* a thunderstorm, so that I do not refer to that form of sheet lightning which commonly goes by the name of *summer lightning*, and which is not, audibly at least, followed by thunder.

The next remarkable feature of the storm is the thunder, corresponding, of course, on the large scale to the snap of an electric spark. Here we are on comparatively sure ground, for sound is very much more thoroughly understood than is electricity. We speak habitually and without exaggeration of the *crash* of thunder, the *rolling* of thunder, and of a *peal* of thunder; and various other terms will suggest themselves to you as being aptly employed in different cases. All of these are easily explained by known properties of sound. The origin of the sound is in all cases to be looked for in the instantaneous and violent dilatation of the air along the track of the lightning flash; partly, no doubt, due to the disruptive effects of electricity of which I have already spoken, but mainly due to the excessive rise of temperature, which renders the air for a moment so briliantly incandescent. There is thus an extremely sudden compression of the air all round the track of the spark; and a less sudden, but still rapid, rush of the air into the partial vacuum which it produces. Thus the sound wave produced must at first be of the nature of a bore or breaker. But as such a state of motion is unstable, after proceeding a moderate distance the sound becomes analogous to other loud but less violent sounds, such as those of the discharge of guns. Were there few clouds, were the air of nearly uniform density, and the flash a short one, this would completely describe the phenomenon, and we should have a thunder *crash* or thunder *clap* according to the greater or less proximity of the seat of discharge. But, as has long been well known, not merely clouds but surfaces of separation of masses of air of different density, such as constantly occur in thunderstorms, *reflect* vibrations in the air; and thus we may have many successive echoes, prolonging the original sound. But there is another cause, often more efficient than these. When the flash is a long one, all its parts being nearly equidistant from the observer, he hears the sound from all these parts simultaneously; but if its parts be at very different distances from him, he hears *successively* the sounds from portions farther and farther distant from him. If the flash be much zigzagged, long portions of its course may run at one and the same distance from him, and the sounds from these arrive simultaneously at his ear. Thus we have no difficulty in accounting for the *rolling* and *pealing* of thunder. It is in fact a mere consequence, sometimes of the reflection of sound, sometimes of the finite velocity with which it is propagated. The usual rough estimate of five seconds to a mile is near enough to the truth for all ordinary calculations of the distance of a flash from the observer.

We now come to an exceedingly strange and somewhat rare phenomenon, to which the name of *fire ball* or *globe lightning* has been given. As we are as yet unable to produce anything of this kind by means of our electrical machines, some philosophers have tried to cut the Gordian knot of the difficulty by denying that any such thing can exist. But, as Arago says, "*Où en serions nous, si nous nous mettions à nier tout ce qu'on ne sait pas expliquer.*" The amount of trustworthy and independent evidence which we possess as to the occurrence of this phenomenon is such as must convince every reasonable man who chooses to pay due attention to the subject. No doubt there is a great deal of exaggeration, as well as much imperfect and even erroneous observation, in almost all of these records. But the existence of the main feature (the fire *ball*) seems to be proved beyond all doubt.

The most marked peculiarities of this species of lightning discharge are its comparatively long duration and its comparatively slow motion. While a spark, or lightning flash, does not last longer than about a millionth part of a second, if so long, globe lightning lasts from one to ten seconds, sometimes even longer, so that a sufficiently self-possessed spectator has time carefully to watch its behaviour. The general appearance is that of a luminous ball, which must be approximately spherical, because it always appears circular in outline, slowly and steadily descending from a thundercloud to the ground. It bursts with a loud explosion, sometimes before reaching the ground, sometimes as it impinges, and sometimes after actually rebounding. Its size varies from that of a child's head to a sphere of little less than a yard in diameter. On some occasions veritable flashes of lightning were seen to proceed from large fire balls as they burst. It is difficult to imagine what these balls can be if they be not a species of natural Leyden jar very highly charged. If it be so, no ordinary lightning rod can possibly prevent danger from it; and we may thus be able to explain the very few cases in which damage has been done by lightning to thoroughly protected buildings. To guard against this form nothing short of a pretty close network of stout copper wires would suffice. Meanwhile I give a brief sketch of *two* out of the long series of descriptions of such phenomena which Arago has patiently collected. The first is given on the authority of Babinet, who was deputed by the Academy of Sciences to make inquiries into the case.

Shortly, but not immediately, after a loud peal of thunder, a tailor who was sitting at his dinner saw the paper ornament which covered his fireplace blown down as if by a gentle breeze, and a globe of fire, about the size of a child's head, came gently out and moved slowly about at a slight elevation above the floor. It appeared bright rather than hot, and he felt no sensation of warmth. It approached him like a little kitten which desired to rub itself in play against his legs; but he drew his feet away, and by slow and cautious movements avoided contact with it. It remained several seconds near his feet, while he leaned forward, and carefully examined it. At last it rose vertically to about the level of his head, so he threw himself back in his chair and continued to watch it. It then became slightly elongated, and moved obliquely towards a hole pierced to the chimney about a yard above the mantel-piece. This hole had been made for the chimney of a stove which was used in winter. "But," as the tailor said, "the globe could not *see* the hole, for paper had been pasted over it." The globe went straight for the hole, tore off the paper, and went up the chimney. After the lapse of time which, at the rate at which he had seen it moving, it would have required to get to the top of the chimney, a terrific explosion was heard, and a great deal of damage was done to the chimney and roofs around it.

The next is even more striking: In June, 1849, in the evening of one of the days when cholera was raging most formidably in Paris, the heat was suffocating, the sky appeared calm, but summer lightning was visible on all sides. Madame Espert saw from her window something like a large red globe, exactly resembling the moon when it is seen through mist. It was descending slowly towards a tree. She at first thought it was a balloon, but its colour undeceived her; and whilst she was trying to make out what it was, she saw the lower part of it take fire ("*Fe vis le feu prendre au bas de ce globe*") while it was still some yards above the tree. The flames were like those of paper burning slowly, with sparks and jets of fire. When the opening became twice or thrice the size of one's hand a sudden and terrific explosion took place. The infernal machine was torn to pieces, and a dozen flashes of zigzag lightning escaped from it in all directions. The *débris* of the globe burned with a brilliant white light, and revolved like a catherine wheel. The whole affair lasted for at least a minute. A hole was bored in the wall of a house, three men were knocked down in the street, and a governess was wounded in the neighbouring school, besides a good deal of other damage.

As another instance, here is a description (taken from Dové) of one which fell at Barbadoes in 1831, during a terrific hurricane. At three o'clock in the morning the lightning ceased for a few moments, and the darkness which enveloped the town was indescribably terrible. Fiery meteors now fell from the clouds; one in particular, of spherical form, and of a deep red colour, fell perpendicularly from a considerable height. This fire ball fell quite obviously by its own weight, and not under the influence of any other external force. As with accelerated velocity it approached the earth it became dazzlingly white, and of elongated form. When it touched the ground it splashed all about like melted metal, and instantly disappeared. In form and size it resembled a lamp globe; and the splashing about at impact gave it the appearance of a drop of mercury of the same size.

I have never seen one myself, but I have received accounts of more than one of them from competent and thoroughly credible eye witnesses. In particular on a stormy afternoon in November, 1868, when the sky was densely clouded over, and the air in a highly electrical state, there was heard in Edinburgh one solitary short, but very loud, clap of thunder. There can be no doubt whatever that this was due to the explosion of a fire ball, which was seen by many spectators, in different parts of the town, to descend towards the Calton Hill, and to burst whilst still about a hundred feet or so above the ground. The various accounts tallied in most particulars, and especially in the very close agreement of the positions assigned to the ball by spectators viewing it from different sides, and in the intervals which were observed to elapse between the explosion and the arrival of the sound.

The remaining phenomena of a thunderstorm are chiefly the copious fall of rain and of hail, and the almost invariable lowering of the barometer. These are closely connected with one another, as we shall presently see.

Almost all the facts to which I have now adverted point to water substance, in some of its many forms, as at least one of the chief agents in thunderstorms. And when we think of other tremendous phenomena which are undoubtedly due to water, we shall have the less difficulty in believing it to be capable of producing thunderstorms also.

First of all let us think of some of the more obvious physical consequences of a fall of a mere tenth of an inch of rain. Suppose it to fall from the lowest mile of the atmosphere. An inch of rain is 5lb. of water per square foot, and gives out on being condensed from vapour approximately 3,000 units of heat on the centigrade scale. The mass of the mile-high column of air a square foot in section is about 360lb., and its specific heat about a quarter. Thus its temperature throughout would be raised by about 33° C., or 60° F. For one-tenth inch of rain, therefore, we should have a rise of temperature of the lowest mile of the atmosphere amounting to 3·3° C., quite enough to produce a very powerful ascending current. As the air ascends and expands it cools, and more vapour is precipitated, so that the ascending current is farther accelerated. The heat developed over one square foot of the earth's surface under these conditions is equivalent to work at the rate of a horse-power for twelve minutes. Over a square mile this would be ten million horse-power for half an hour. A fall of one-tenth of an inch of rain over the whole of Britain gives heat equivalent to the work of a million millions of horses for half an hour! Numbers like these are altogether beyond the limits of our understanding. They enable us, however, to see the full explanation of the energy of the most violent hurricanes in the simplest physical concomitants of the mere condensation of aqueous vapour.

I have already told you that the source of atmospheric electricity is as yet very uncertain. Yet it is so common and so prominent a phenomenon in many of its manifestations that there can be little doubt that innumerable attempts have been made to account for it. But when we consult the best treatises on meteorology we find it either evaded altogether or passed over with exceedingly scant references to evaporation or to vegetation. This notion is due to Pouillet. Peltier suggested that the whole earth is permanently electrified. Not finding anything satisfactory in books, I have consulted able physicists, and some of the ablest of meteorologists, in all cases but one with the same negative result. I had, in fact, the feeling which every one must experience who attempts to lecture on a somewhat unfamiliar subject, that there *might* be much known about it which I had not been fortunate enough to meet with. Several years ago I was experimentally led to infer that mere *contact* of the particles of aqueous vapour with those of air, as they fly about and impinge according to the modern kinetic theory of gases, produced a separation of the two electricities, just as when zinc and copper are brought into contact the zinc becomes positively electrified and the copper negatively. Thus the electrification was supposed to be the result of chemical affinity.* Let us suppose, then, that a particle of vapour, after impact on a particle of air, becomes electrified positively (I shall presently mention experiments in support of this supposition), and see what farther consequences will ensue when the vapour condenses. We do not know the mechanism of the precipitation of vapour as cloud, and we know only partially that of the agglomeration of cloud particles into rain drops; but of this we can be sure that, if the vapour particles were originally electrified to any finite potential, the cloud particles would be each at a potential enormously higher, and the rain drops considerably higher still. For, as I have already told you, the potential of a free charged sphere is proportional directly to the quantity of electricity on it and inversely to its radius; so when eight equal and equally charged spheres unite into one sphere of double the radius, its potential is four times that of each of the separate spheres. The potential in a large sphere so built up is, in fact, directly proportional to its surface as compared with that of any one of the smaller equal spheres of which it is built.

Now, the number of particles of vapour which go to the formation of a single average rain drop is about 300 millions of millions of millions, so that the potential of the drop would be about 50 billion times as great as that of a particle of vapour. On the very lowest estimate this would be almost incomparably greater than any potential we can hope to produce by means of electrical machines.

But this attempt at explanation of atmospheric electricity presents two formidable difficulties at the very outset.

1. How should the smaller cloud particles ever unite if they be charged to such high potentials, which of course must produce intense repulsions between them?

* *Proc.*, R.S.E., 1875. In 1876 a somewhat similar idea was published by Luddens; but he ascribes the electrification to *friction* between air and water vapour.

2. Granting that, in spite of this, they do so unite, how are they separated from the mass of negatively electrified air in which they took their origin?

I think it is probable that the second objection is more imaginary than real, since there is no doubt that the diffusion of gases would speedily lead to a great spreading about of the negatively electrified particles of air from among the precipitated cloud particles into the less highly electrified air surrounding the cloud. And if the surrounding air were equally electrified with that mixed with the cloud, there would be no electric force preventing gravity from doing its usual work. This objection, in fact, holds only for the *final* separation of the whole moisture from the oppositely electrified air; and gravity may be trusted to accomplish this. That gravity is an efficient agent in this separation is the opinion of Professor Stokes. It must be observed that as soon as the charge on each of the drops in a cloud rises sufficiently, the electricity will pass by discharge to those which form the bounding layer of the cloud.

The first objection is at least partially met by the remark that in a cloud mass when just formed, if it be at all uniform, the electric attractions and repulsions would approximately balance one another at every point, so that the mutual repulsion of any two water drops would be almost compensated except when they came very close to one another.

But there is nothing in this explanation inconsistent with the possibility that the particles of water may be caused to fly about repeatedly from cloud to cloud, or from cloud to an electrified mass of air; and in many of these regions the air, already in great part deprived of its moisture, may have become much cooled by expansion as it ascends, so that the usual explanation of the production of hail is not, at least to any great extent, interfered with.

I may here refer to some phenomena which seem to offer, if closely investigated, the opportunity for the large scale investigations which, as I shall presently show, will probably be required to settle the source or sources of atmospheric electricity.

First, the important fact, well known nearly 2,000 years ago, that the column of smoke and vapour discharged by an active volcano gives out flashes of veritable lightning. In more modern times this has been repeatedly observed in the eruptions of Vesuvius and other volcanos—such as, for instance, the island of Sabrina. It is recorded by Sir W. Hamilton (British ambassador at Naples at the end of last century) that in the eruption of 1794 these flashes were accompanied by violent peals of thunder. They destroyed houses in the neighbourhood of the mountain, and are said to have done considerable damage even at places 250 miles off, to which the cloud of volcanic dust and vapour was carried by the wind. I will read a couple of extracts from Hamilton's paper. It is in the *Philosophical Transactions* for 1795:—

"The electric fire in the year 1779, that played constantly within the enormous black cloud over the crater of Vesuvius, and seldom quitted it, was exactly similar to that which is produced on a very small scale by the conductor of an electrical machine communicating with an insulated plate of glass, thinly spread over with metallic filings, &c., when the electric matter continues to play over it in zigzag lines without quitting it. I was not sensible of any noise attending that operation in 1779; whereas the discharge of the electrical matter from the volcanic clouds during this eruption, and particularly the second and third days, caused explosions like those of the loudest thunder; and, indeed, the storms raised evidently by the sole power of the volcano resembled in every respect all other thunderstorms, the lightning falling and destroying everything in its course. The house of the Marquis of Berio at S. Jorio, situated at the foot of Vesuvius, during one of these volcanic storms was struck with lightning, which, having shattered many doors and windows, and damaged the furniture, left for some time a strong smell of sulphur in the rooms it passed through. Out of these gigantic and volcanic clouds, besides the lightning, both during this eruption and that of 1779, I have, with many others, seen balls of fire issue, and some of a considerable magnitude, which, bursting in the air, produced nearly the same effect as that from the air balloons in fireworks, the electric fire that came out having the appearance of the serpents with which those firework balloons are often filled. The day on which Naples was in the greatest danger from the volcanic clouds, two small ball of fire, joined together by a small link like a chain shot, fell close to my *casino* at Posilipo. They separated, and one fell in the vineyard above the house, and the other in the sea, so close to it that I heard a splash in the water; but, as I was writing, I lost the sight of this phenomenon, which was seen by some of the company with me, and related to me as above."

"The Archbishop of Taranto, in a letter to Naples, and dated from that city the 18th of June, said, 'We are involved in a thick cloud of minute volcanic ashes, and we imagine that there must be a great eruption either of Mount Etna or of Stromboli.' The bishop did not dream of their having proceeded from Vesuvius, which is about 250 miles from Taranto. We have had accounts also of the fall of the ashes during the late eruption at the very

Digitized by Google

extremity of the province of Leece, which is still farther off; and we have been assured likewise that those clouds were replete with electrical matter. At Martino, near Taranto, a house was struck and much damaged by the lightning from one of these clouds. In the accounts of the great eruption at Vesuvius in 1631 mention is made of the extensive progress of the ashes from Vesuvius, and of the damage done by the *ferilli*, or volcanic lightning, which attended them in their course."

Sabine, while at anchor near Skye, remarked that the cloud cap on one of the higher hills was permanently luminous at night, and occasionally gave out flashes resembling those of the aurora. I have not been able to obtain farther information as to this very important fact; but I have recently received a description of a very similar one from another easily accessible locality.

My correspondent writes from Galway, to the following effect, on the 2nd of January, 1880:—

"At the commencement of the present unprecedentedly long and severe storm the wind blew from south-west and was very warm. After blowing for about two days it became, *without change of direction*, exceedingly bitter and cold, and the rain was, from time to time, mixed with sleet and hail, and lightning was occasional. This special weather is common for weeks together in March or early April. The air is (like what an east wind brings in Edinburgh) cold, raw, dry, and in every way uncomfortable, especially to people accustomed to the moist Atlantic winds. During these weeks series of small clouds, whose shadows would only cover a field of a few acres, seem to start at regular intervals from the peaks of hills in Connemara and Mayo. They are all more or less charged with electricity. From high ground, behind the city, I have at one time seen such a cloud break into lightning over the spire of the Jesuits' church. At another I have seen such a cloud pour down in a thin line of fire, and fall into the bay in the shape of a small incandescent ball. On one occasion I was walking with a friend, when I remarked, 'Let us turn and make a run for it. We have walked unwittingly right underneath a little thundercloud.' I had scarcely spoken when a something *flashed on the stony ground at our very feet*, a tremendous crash pealed over our heads, and the smell of sulphur was unmistakable. I fancy that I have been struck with these phenomena more than others, from the circumstance that they have always interfered with my daily habits. My walks extended to great distances and to very lonely districts. Now, these small local spurts of thunderstorms would hardly excite attention in the middle of a town, all the less as the intervening weather is bright, though raw—these spurts coming on every three or four quarters of an hour. Neither would they excite much attention in the country, as, while such a little storm was going on in one's immediate neighbourhood, you would see at no great distance every sign of fine weather. In fact they always seem to me like the small change of a big storm."

My correspondent, though a good observer and eloquent in description, is not a scientific man. But it is quite clear from what he says that a residence of a few weeks in Galway, at the proper season, would enable a trained physicist to obtain, with little trouble, the means of solving this extremely interesting question. He would require to be furnished with an electrometer, a hygrometer, and a few other simple pieces of apparatus, as well as with a light suit of plate armour, not of steel, but of the best conducting copper, to insure his personal safety. Thus armed he might fearlessly invade the very nest or hatching place of the phenomenon, on the top of one of the Connemara hills. It is to be hoped that some of the rising generation of physicists may speedily make the attempt, in the *spirit* of the ancient chivalry, but with the offensive and defensive weapons of *modern* science.

Another possible source of the electricity of thunderstorms has been pointed out by Sir W. Thomson. It is based on the experimental fact that the lower air is usually charged with negative electricity. If ascending currents carry up this lower air the electricity formerly spread in a thin stratum over a large surface may, by convection, be brought into a very much less diffused state, and thus be raised to a potential sufficient to enable it to give a spark.

However the electrification of the precipitated vapour may ultimately be accounted for, there can be no doubt of the fact that at least as soon as *cloud* is formed the particles are electrified; and what I have said as to the immense rise of potential as the drops gradually increase in size remains unaffected. I have tried various forms of experiment, with the view of discovering the electric state of vapour mixed with air. For instance, I have tested the vapour which is suddenly condensed when a receiver is partially exhausted; the electrification of cooled bodies exposed to moist air from a gasholder; and the deposition of hoar frost from a current of moist air upon two polished metal plates placed parallel to one another, artificially cooled, and connected with the outer and inner coatings of a charged jar. All have given results, but as yet too minute and uncertain to settle such a question. These experiments are still in progress. It appears probable, so far, that the problem will not be finally solved until experiments are made on a scale much larger than is usual in laboratories. Kalischer has quite recently attempted to disprove this theory, but his experiments are all liable to the same objection, they were made on much too small a scale.

A great thunderstorm in summer is in the majority of cases preceded by very calm sultry weather. The atmosphere is in a state of unstable equilibrium, the lower strata are at an abnormally high temperature, and highly charged with aqueous vapour. It is not easy, in a popular lecture like this, to give a full account of what constitutes a state of stable equilibrium, or of unstable, especially when the effects of precipitation of vapour are to be largely taken into account. It is sufficient for my present purpose to say that in all cases of thoroughly stable equilibrium, a slight displacement *tends to right itself;* while, in general, in unstable equilibrium, a slight displacement tends to increase. Now, if two cubic feet of air at different levels could be suddenly made to change places, without at first any other alteration, and if, on being left to themselves, each would, under the change of pressure which it would suddenly experience, and the consequent heating or cooling, with its associated evaporation or precipitation of moisture, tend to regain its former level, the equilibrium would be stable. This is not the case when the lower strata are very hot, and fully charged with vapour. Any portion accidentally raised to a higher level tends to rise higher, thus allowing others to descend. These, in consequence of their descent, tend still further to descend, and thus to force new portions up. Thus, when the trigger is once pulled, as it were, we soon have powerful ascending currents of hot moist air, precipitating their moisture as cloud as they descend, cooling by expansion, but warmed by the latent heat of the vapour condensed. This phenomenon of ascending currents is strongly marked in almost every great thunderstorm, and is precisely analogous to that observed in the centre of a West Indian tornado and of a Chinese typhoon.

When any portion of the atmosphere is ascending it must be because a denser portion is descending, and whenever such motions occur *with acceleration* the pressure must necessarily be diminished, since the lower strata are not then supporting the whole weight of the superincumbent strata. If their whole weight were supported they would not descend. Thus even a smart shower of rain must directly tend to lower the barometer. [A long glass tube, filled with water, was suspended in a vertical position by a light spiral spring, reaching to the roof of the hall. A number of bullets hung at the top of the water column, attached to the tube by a thread. When the thread was burned, by applying a lamp, the bullets descended in the water, and *during their descent* the spring contracted so as to raise the whole tube several inches.]

In what I have said to-night I have confined myself mainly to *great* thunderstorms, and to what is seen and heard by those who are within their sphere of operation. I have said nothing of what is commonly called *summer lightning*, which is probably, at least in a great many cases, merely the faint effect of a distant thunderstorm, but which has also been observed when the sky appeared tolerably clear, and when it was certain that no thunderstorm of the ordinary kind had occurred within a hundred miles. In such cases it is probable that we see the lightning of a storm which is taking place in the upper strata of the atmosphere, at such a height that the thunder is inaudible, partly on account of the distance, partly on account of the fact that it takes its origin in air of small density.

Nor have I spoken of the aurora, which is obviously connected with atmospheric electricity, but in what precise way remains to be discovered. Various theories have been suggested, but decisive data are wanting. Dr. Balfour Stewart inclines to the belief that great auroras, visible over nearly a whole terrestrial hemisphere, are due to inductive effects of changes in the earth's magnetism. This is not necessarily inconsistent with the opinion that, as ordinary auroras generally occur at times when a considerable change of temperature takes place, they are phenomena due to the condensation of aqueous vapour in far less quantity, but through far greater spaces, than the quantities and spaces involved in ordinary thunderstorms.

We now *know* that electricity is not a substance; the "electric fluid" is only read of in the reports of penny-a-liners. But if it be a form of energy due to stresses in the luminiferous medium, how do we account for the fact that positive and negative electricity are always developed simultaneously in *equal* quantities?

We can form a rough analogy thus:—Take hold of the middle of a stretched rope and twist it. Whatever amount of twist is thus given to one end, *exactly* as much untwisting is simultaneously given to the other. Or even more simply. Take a stretched india rubber string firmly by the middle, and move your hand towards either end. That end is *relaxed* and the other simultaneously extended to equal amounts.

Thus there is nothing to hinder us from supposing that a distorsion of any kind in the ether may *necessarily* be accompanied by an *equal* and *opposite* distorsion of a similar kind, though the exact mechanism of the process may long elude the intellects of the greatest philosophers.

Cheques and P.O. Orders to be made payable to C. H. W. BIGGS.

Advertisements intended for the current week's issue must be handed in not later than Thursday, 4 p.m.

ANSWERS TO CORRESPONDENTS.

NON-GULLER OF THE PUBLIC.—*We shall have pleasure in inserting your letter if we may append your name to it.*

J. CHAPMAN.—*The chapter on Electro-Metallurgy of Mr. Sprague's book cannot be obtained separately, but it may be possible to obtain a second-hand copy of the first edition at a low price. Watts's "Electro-Metallurgy" is likely to be the most suitable for you. The way to use aqua fortis depends on the required purpose, as it must be diluted to strengths suitable for cleansing different metals. But it is usual to just dip the object in strong aqua fortis for a moment as a finishing preparation before beginning to coat, in order to produce a surface best suited for adhesion. It should not be used with substances of the nature of pewter or Britannia metal, which should be cleaned with alkalis.*

THE POST OFFICE AND THE TELEPHONE.

When we penned our article on the subject of Telephone Companies' grievances a fortnight ago we had no idea that we were meeting the forces of an organised army doing battle for the interests of the companies against the rights of the Post Office. But so it would seem; for if the usual indications are to be trusted, the press has been set on to badger the Postmaster-General, and the usual methods employed in the lobbies to bring parlimentary influence to bear upon him. The object is not precisely stated. But we can take our choice; either it is to obtain complete independence, or to force a State purchase. There can be no object except one of these two. Ostensibly the agitation is being got up with a view to the former, but as the promoters may be credited with some sense it is not to be supposed that they expect to succeed, and it follows that their ulterior aim is to get themselves bought up. Now, so far as anything we have said, or are about to say, is concerned, the question of purchase does not come before us. When the companies frankly avow their object we may discuss it; meanwhile we make them a present of the admission that we have no objection to the telephone business being taken over by the State, and rather regret that this was not done in the first instance. What the bargain should be is a different matter; and what we particularly take exception to at present are the methods adopted to exaggerate the companies' importance and swell the value of what they have to sell. Their own manifesto, although illogical and full of erroneous assumptions, is moderate in its tone; but it is evident that the lines of argument and material worked up by the press in support of the document are utterly untrustworthy and studiously offensive. An article in the *Edinburgh Courant* of June 5th is a notable sample of this, and it has been reprinted apparently for general circulation. *The Times* a week later published a similar article, quite as objectionable in its manner, and if possible more ridiculous in argument. Let us see what these two typical utterances amount to.

It is alleged by the *Courant* that the action of the Postmaster-General is defended on the ground that, having paid ten millions for the telegraphs, it is necessary to protect the telegraph revenue. Would the ground be different, we may ask, if the price had been less? It is usual to protect public revenue against all kinds of smuggling, and this on purely financial grounds, quite distinct from what the right to do so may have originally cost. *The Times* goes further, and roundly asserts that the permanent officials of the Post Office are personally interested in maintaining the revenue of the telegraph because they were responsible for its being purchased at an extravagant price. We look in vain for evidence in support of this scandalous charge against a body of public servants who are unable to defend themselves. There is absolutely no evidence of the kind; the outcry, in fact, being merely the echo of political teaching, which of late has taken views on the rights of property differing materially from those which prevailed when the purchase was made. However, it is pleasant to note that extravagant bargains are not in favour with the friends of the telephone companies. It is to be hoped they will stand firmly to their principles if ever another transaction of a like kind comes on for discussion.

But, says the *Courant*, the apprehension of loss of revenue is altogether "hollow and misleading." The telephone and the telegraph are "not competitors," but "healthy rivals," the effect of whose rivalry is "to increase the demand for both facilities." Statistics are mentioned as bearing out this courageous assertion, but they are not given, and we confidently assert that they cannot be produced, for the simple reason that they involve a contradiction, the very essence of such a rivalry being to absorb and transfer the rival's business, not to increase it. At all events this is obviously the case in respect to a rivalry between telegraph and telephone, for whichever system is found most convenient will send the other to the wall. One chief grievance of the companies is that the Post Office will not let them, without paying an equitable price for it, do business which would wipe out any remaining distinction between telephony and telegraphy. Let us, say the companies, connect large towns by trunk lines. By all means, reply the Post Office, but you must pay for it if you do, for we do not believe—nobody believes—in your pretence that it would increase our business; on the contrary, it would damage it to the extent of your gain, and more. Either, therefore, you must pay for such an unlooked for concession—a concession which was never dreamed of when our bargain was first made—or we ourselves will make the trunk lines

Digitized by Google

when we see the public demand for it. As regards the proposal to connect private customers with telegraph offices by means of the telephone, the only proposal which looks like feeding the telegraph by "increasing the demand for facilities" would in reality be affording undue facilities to private individuals, and, as affecting the delivery of telegrams, contrary to the spirit of the Telegraph Acts. What the companies were really driving at had they "been left free to develop their business in their own way" is graphically set forth in *The Times* article: "There would by this time have been arrangements by which in every town in the kingdom any one might have gone into the office, might have been placed in direct communication with any other person in the same or in any other town, and have been enabled for a small charge to converse with him unrestrictedly." We need not waste words on the fancy sketch of our leading organ; but this we may say, if it is in any sense a true picture of what might have happened, to make the tableau complete, the wreck of the postal telegraphs ought to be added in the background, with ten millions of public money buried under the ruins.

But the money loss, we are told, is as nothing compared to the moral delinquency of the Postmaster-General. *The Times* is overflowing with morality on this topic. We should have thought that for clients who deliberately started an opposition which they perfectly well knew could not be sustained either in law or equity the less said about morality the better. But according to *The Times* it was immoral of the Post Office to accept the verdict of a court of law and not go to Parliament to get it reversed. It is immoral to deprive inventors of the fruits of their discovery—that is to say if the Post Office is the guilty party—but apparently not if the shareholders of a big company have committed the wrong. Some inventors have certainly suffered, but their complaints have not been directed exclusively or even chiefly against the Post Office. Lastly, it was immoral to claim the telephone as a telegraph, because "the principle on which the telephone rests is entirely different from that of the telegraph." So, too, does the locomotive differ in principle from that of the mail coach. The moral question, we should have thought, comes in with the burden to be carried. The Postmaster-General did not abdicate his exclusive right to carry letters because somebody else invented a faster conveyance for them; nor is it likely that Mr. Fawcett will betray his duty to the country in obedience to a new code of ethics invented for the sole benefit of "healthy rivals."

THE INDUCTION OF CURRENTS IN CORES.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 104.)

Induction in a Divided Core.

To ascertain under what circumstances the heating, according to Joule's law, of a properly divided core might become sensible—general considerations telling us that it must be very small—let us, to bring the matter under mathematical treatment, specify a particular manner of division. This will be most shortly described by referring to a plane section of the core perpendicular to its axis. Divide the circular section by radii into sectors, and let the sectors be of two sets, one set having all an opening of say 1°, and the other set of say 9°. These are to alternate. The small sectors to be filled up with dielectric material, the large with metal. We thus stop the free flow of the circular induced currents in the core by the insulating barriers placed perpendicular to the lines of E.M.F. There are 36 condensers (the number is immaterial), joined up in sequence, which become charged and discharged during the passage of an oscillatory current in the coil circuit, and according to old notions electricity accumulates on the bounding surfaces of the condensers. According to Maxwell's views, however, the currents flow in the same closed circuits as if the core were solid metal, but in the dielectric portions the electric elasticity brings a counter E.M.F. into play, thus preventing the passage of a continuous current, and weakening the strength of oscillatory currents.

Let ρ_1 and c_1 be the resistance and the electrostatic capacity per unit volume of the compound core, later more particularly defined. Let e, as before, be the impressed force per unit length arising from electro-magnetic induction, γ the current density, and now, in addition, D the electric displacement per unit area perpendicular to the lines of flow. Then, instead of the former equation, $e=\rho\gamma$, we shall have

$$e=\rho_1\gamma+\mathrm{D}/c_1 \qquad (55)$$

with the additional relation

$$\gamma=\dot{\mathrm{D}} \qquad (56)$$

Differentiating equation (55) to t, and getting rid of D, by (56), we obtain

$$c_1\dot{e}=c_1\rho_1\dot{\gamma}+\gamma \qquad (57)$$

which we must substitute for the old $e=\rho\gamma$.

Equation (10) holds as before, connecting the current and the magnetic force. So does equation (12), giving the E.M.F. of induction, if we give to μ therein a new value, to be given presently, on account of the core not being homogeneous. Eliminating e between equations (57) and (12) we obtain

$$\frac{1}{r}\frac{d}{dr}r\frac{d}{dr}(\dot{\mathrm{H}}+\mathrm{H}/\rho_1c_1)=\frac{4\pi\mu}{\rho_1}\ddot{\mathrm{H}} \qquad (14a)$$

instead of equation (14) for the characteristic equation of magnetic force in the compound core. Its solution, suitable for oscillatory currents, requires the use of two functions of r, say H_1 and H_2, satisfying

$$\left.\begin{aligned}\frac{1}{r}\frac{d}{dr}r\frac{d}{dr}(\mathrm{H}_1+\mathrm{H}_2/\rho_1c_1)&=-x_1\mathrm{H}_2\\ \frac{1}{r}\frac{d}{dr}r\frac{d}{dr}(\mathrm{H}_2+\mathrm{H}_1/\rho_1c_1)&=+x_1\mathrm{H}_1\end{aligned}\right\} \qquad (22a)$$

instead of equations (22). Here x_1 stands for $4\pi\mu/\rho_1$. And H_1 and H_2 may be found in series of ascending powers of r by

$$\left(\frac{1}{r}\frac{d}{dr}r\frac{d}{dr}+\frac{1}{\rho_1c_1}\right)^2\mathrm{H}_1=-x_1^2\mathrm{H}_1 \qquad (23a.)$$

which takes the place of (23).

Now as regards ρ_1, c_1, and μ_1. If the ratio of the angles of the wedges occupied by conducting and insulating material be n_1/n_2, and $n_1+n_2=1$, we shall have, if ρ be the specific resistance of the conductor,

$$\rho_1=n_1\rho,$$

the specific resistance of the compound core becoming somewhat reduced. And, if μ_1 and μ_2 be the magnetic permeabilities of the conducting and dielectric parts of the core, we have

$$\mu=n_1\mu_1+n_2\mu_2,$$

giving the value of μ to be used in equation (12) and in (14a) just given. Thus the permeability of the compound core, if the conducting part be of iron, is somewhat reduced.

Lastly, if c be the electrostatic capacity per unit volume of the dielectric only, that of the compound core is

$$c_1=c/n_2.$$

The time constant ρ_1c_1 which appears in the characteristic equation (14a) is thus given by

$$\rho_1c_1=\rho cn_1/n_2,$$

where ρ and c belong to the metal and dielectric separately, ρ_1 and c_1 to the compound. The value of this time constant is the same whether there are 20 or 20,000 wedges, alternately metal and dielectric, provided the ratio n_1/n_2 of the spaces they occupy, which appears in the last equation, is kept the same.

Digitized by Google

But this time interval must in general be extremely small. For c the electrostatic capacity of unit volume of the dielectric is $K/4\pi$ in electrostatic measure, K being the dielectric constant, and, in the electro-magnetic measure here required, we must further divide by V^2, where V is the velocity of light, $= 3 \times 10^{10}$. Thus we have

$$\rho_1 c_1 = \rho K n_1 / 4\pi V^2 n_2 ;$$

and K being a small number, and also $\rho = 10,000$ for iron, whilst V^2 is very large, $\rho_1 c_1$ must be very small, unless we make n_1/n_2 extravagantly large—*i.e.*, reduce the thickness of the dielectric wedges greatly, compared with that of the conducting wedges, which of course has the effect of increasing the capacity of the condensers. If this impracticable thinness of dielectric could be carried out with proper insulation, we should, with an oscillatory current in the coil, make the induced currents in the core less by as little as we pleased from what they would be in a solid conducting core, and the heating of the compound core similarly approach that of the solid one.

The influence of increased speed may also be noticed. Consider a single closed circuit of conductors and condensers in series, such as we obtain by confining ourselves to the portion of core contained between the cylinders of radii r and $r+1$. If we further take only the unit length parallel to the axis, the section of the circuit has the unit area. R being the resistance of the circuit, viz., the sum of the resistances of the conducting portions; and C its capacity, viz., the reciprocal of the sum of the reciprocals of the capacities of the single condensers, we have

$$E = R\gamma + Q/C,$$

similarly to (55), E being the total impressed force in the circuit, γ the current, and Q the common charge of each condenser. Also $\gamma = \dot{Q}$, whence

$$C\dot{E} = RC\dot{\gamma} + \gamma.$$

Now let the E.M.F. be of the simple harmonic type E sin nt, where E is constant; the solution for the current is then

$$\gamma = \frac{nCE}{\{1 + (nCR)^2\}^{\frac{1}{2}}} \cos(nt - \tan^{-1} nCR),$$

and the heat developed per second in the conducting part of the circuit is

$$\frac{\frac{1}{2}R(nCE)^2}{1 + (nCR)^2} = \frac{1}{2}\frac{E^2}{R}\left\{ 1 + (nCR)^{-2} \right\}^{-1}.$$

Here $\frac{1}{2}E^2/R$ is what the heating would be if the condensers were short circuited; so, from the value of nCR we can easily see how much it is reduced by the insertion of the condensers. The value of RC is the same as that of $\rho_1 c_1$ before given; also $n = 2\pi v$, v being the wave frequency. By sufficiently increasing the speed we may make the heating approach as nearly as we like to $\frac{1}{2}E^2/R$ without necessarily making the dielectric portions of the circuit excessively thin; but it may be readily seen that for the heating in the closed circuit of condensers to be comparable with what it would be were they short circuited, or the dielectric removed and conducting matter substituted, the frequency v must, on account of the presence of V^2 in the expression for RC, be itself comparable with the frequency of light vibrations. If, then, a properly divided iron core with oscillatory currents, or with such super-imposed on a steady current passing in a coil surrounding it, should become sensibly heated, such heating cannot have arisen from the Joule effect of the induced currents.

Transmission of Energy into a Conducting Core.

The magnetic energy per unit volume being $\mu H^2/8\pi$, where H is the magnetic force as before, if we suppose the magnetisation to be wholly induced, the magnetic energy per unit length of core of radius r is given by

$$\frac{\mu}{8\pi}\int 2\pi r dr . H^2 = \frac{\mu}{4}\int H^2 r dr \quad . \quad . \quad . \quad (58)$$

Also the rate of dissipation of energy in the same portion, being $\rho\gamma^2$ per unit volume, is given by

$$2\pi\rho\int \gamma^2 r dr = \frac{\rho}{8\pi}\int H'^2 r dr \quad . \quad . \quad . \quad . \quad (59)$$

since $\gamma = -H'/4\pi$. Now, energy can only enter the portion of core considered across its boundary, and, after having entered, is either stored up temporarily as magnetic energy, or is dissipated as heat through induced currents. Hence the rate of passage of energy into the space from outside equals the sum of the rate of increase of magnetic energy and of the rate of dissipation within the space. Thus, if by W we denote the amount of energy entering the core per second per unit area of its bounding surface, we obtain, by (58) and (59),

$$2\pi r W = \frac{\mu}{2}\int H\dot{H} r dr + \frac{\rho}{8\pi}\int H'^2 r dr$$

Here, by equation (14),

$$\dot{H} = \frac{\rho}{4\pi\mu r}\frac{d}{dr}(rH').$$

Making the substitution and integrating, we get

$$W = \frac{\rho}{4\pi\mu}\frac{dT}{dr} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (60)$$

where $T = \mu H^2/8\pi$, the magnetic energy per unit volume. From this we see that the transmission of energy takes place from places of greater to places of less force irrespective of sign, and that the rate of transference per second is proportional to the rate of decrease of the density of the magnetic energy in the direction of transference.

This remarkably simple property, which applies to every part of the core at every moment, according to which the transmission of magnetic energy whilst induced currents are lasting is determined solely by the space variation of its density, is not a general property of induction in conductors. If we inquire what the corresponding property is in general, by examining the rate at which energy is entering any given portion of a conductor through the imagined surface separating it from the rest, such being equal to the sum of the rate of increase of the magnetic energy and of the rate of dissipation as heat by induced currents within the portion considered, using the general relations

$$\text{curl } H = 4\pi\gamma, \text{ and } V^2 H + 4\pi\mu\dot{H}/\rho = 0,$$

we find that W_s, the rate of passage of energy at any point across the surface whose normal has any direction s per unit areas, or, briefly, the rate of transference in the direction s equals $\rho/4\pi$ times the component along s of the vector product of the current density and the magnetic force at the point. Or

$$W_s = \frac{\rho}{4\pi} V\gamma H$$

in the brief quaternion form. The direction of maximum transference is therefore perpendicular to the plane containing the magnetic force and the current directions, and its amount per second proportional to the product of their strengths and to the sine of the angle between their directions.

Eliminating the current, and expressing the relation in terms of magnetic force only, we find

$$W_s = -\frac{\rho}{4\pi\gamma}\frac{dT}{ds} + \frac{\rho}{(4\pi)^2} H \frac{dH_s}{dh} \quad . \quad . \quad . \quad (61)$$

where T is, as before, the density of the magnetic energy, H_s the component of H in the direction s, and h the direction of H itself.

Now, if we confine H to a constant direction, so that it cannot vary in strength in that direction, its component in any other direction s also does not vary along h. Then (61) reduces to

$$W_s = -\frac{\rho}{4\pi\mu}\frac{dT}{ds},$$

of which (60) is a special case.

(TO BE CONTINUED.)

ELECTRICITY AND LIGHT.—III.

BY JOHN T. SPRAGUE.

(CONTINUED FROM PAGE 82.)

22. *Sounds are produced by energy* transmitted by undulations in the air or other substance, exactly as the energy is transferred by wave motion from the centre of a water pool; but the undulations are of a different order. There is no real difference, however. The fact is simply due to the different forces which resist the motion. The wave of water is a *vertical rise and fall*, because it is generated against the force of gravitation, and in a medium which has its weakest resistance on its surface. Therefore the motion of the molecules of water must needs occur in the line of least resistance and greatest force, and the energy is propagated at right angles to the undulation.

23. But sound being propagated in a uniform medium, as the air, which presents no direction of least resistance, and not against an active force, but against the elastic power of the medium itself, the result is a succession of pressures and reactions, which result in a series of spherical condensations and rarefactions—that is to say, undulations in the line of transmission. The conditions really resemble those of the line of billiard balls (Secs. 11 and 17). This involves no difference of principle, but merely a result of similar action under different conditions; and the pendulum, which as stated (Sec. 20) is the elementary type of all wave motion, presents both forms of undulation to the eye, as it shows true wave motion in its rise and fall, and the alternating form by its to and fro swing across its line of rest.

24. *The transmission of mechanical energy by sound* is easily exhibited. A single sound is of the nature of a blow such as would be transmitted by one rise and fall of the pendulum if allowed to strike another, or exactly like the motion of the last ball of the row (Sec. 11). Such a sound is illustrated by the stroke of a woodcutter's axe, which may be heard after the stroke itself is seen by a space of time dependent on the distance, sound travelling in air at the rate of 1,120 feet per second at ordinary temperature (62° F.), while light traverses some 185,000 miles per second. Now, if we have a room with two doors, one opening outwards, or with a hinged window, the sharp opening of one door will force the other open if not fastened; the elastic air in fact propagates the energy across the room just as a rigid bar would do. Again, if a stretched membrane, such as a tambourine, be supported on a stand, it will be found to vibrate to any sound, being literally struck by the waves of sound; the same also may be felt in a sheet of paper held in the hand.

25. *The perception of sound* is exactly of this nature. It is effected by a delicate organ of *touch* rather than of a special sense, for the ear consists really of the tambourine connected to a series of rods tuned to vibrate to their corresponding rates of wave motion, and so to transfer the mechanical energy carried in the portion of the waves which enter the ear into a succession of vibrations to be perceived by the special nerve arranged to transform those purely mechanical vibrations into mental perceptions. Of this stage we know nothing whatever; we can trace the transfer of energy up to the nerve, but how it is translated into perception we are utterly ignorant of, as of the process of all mental operations. But the point to which we have now come is the clear recognition that *sound itself has no existence*; in the air it is merely a motion of the particles of air, a transfer of radiant mechanical energy. This only *becomes sound in the ear itself* in the act of appreciation of the nature of the transmitting motion, and particularly of the rate of the undulations set up.

26. *Musical notes* are distinguished from other sounds as being caused by the continuation of a definite rate of undulation, the production of this being controlled by the conditions of the generator and the action and reaction of the force and resistance. The rate of swing of a pendulum is controlled by the length of the rod and the force of gravitation at the spot. We have seen that the swing of the pendulum is the type of all wave motion, and so also the length of the pendulum rod is the type of the production of musical sounds, that is of the wave length of notes. Thus a double length gives a double wave length or period of undulation, and notes which "harmonise" together and form "chords" agreeable to the ear are those whose rates are exactly proportioned to each other's intervals, while "discords" are produced by notes whose rates do not unite as definite proportionals. The length of a cord under a fixed strain, such as a piano wire, answers to the length of the pendulum, and produces the corresponding undulation in the air by vibration under a stress and the reacting elasticity of the cord.

27. *The musical scale* is a system of proportioned wave lengths or times so related as to please the sense of hearing, because based upon the mathematical relations of the intervals. It may be commenced upon any rate of vibration selected, but its intervals must hold the fixed relations. The number of vibrations which represents the note written on the second space, or the treble C or Do, is the "pitch," which varies from 424 to 440 per second; but whatever this is the relations among the several notes are—

Do	Re	Me	Fa	Sol	La	Si	Do
C	D	E	F	G	A	B	C
1	$\frac{9}{8}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{5}{3}$	$\frac{15}{8}$	2
440	495	550	$586\frac{2}{3}$	660	$733\frac{1}{3}$	825	880

Thus a musical *octave* represents the interval in which the rate of vibration is doubled, each note having its rate doubled in the next higher octave.

The lowest sound recognised by the ear as a definite musical note has a rate of 27 per second, and the highest about 3,520. These are the ranges of a 7-octave piano, though *sounds* may be heard of lower rate and up to about 24,000.

28. *Notes are absorbed and reproduced by agencies which can produce them.* Thus, each glass tumbler or lamp-shade has a note proper to itself, as a bell has; and they will sound this note when an instrument or singer produces it. So also the wires of a piano will take up and sound each its own notes. They will also be sounded by their harmonics, though not so strongly. So powerful is this faculty for absorption, that it is quite possible to split a glass by singing its proper note strongly. It is this faculty of taking up a sounding body's specific vibration that was utilised in the harmonic telegraphs of Gray, La Cour, and others whose experiments preceded, and ultimately led to the invention of, the telephone. All of these depended on the intermission of currents produced by musical sounders, such as tuning forks, each producing its own rate of intermission. The receivers consisted of similar musical sounders under the influence of electro-magnets actuated by the current, so that only those would sound which corresponded to those which acted as transmitters.

29. *Interference* is the mutual action of two wave systems. In the pond of water (Secs. 17 and 21), the waves are reflected from the edges in circles which cross the original ones, or two distinct systems may be originated by two stones. It will be seen that however numerous the wave circles may be, they do not interfere with each other in the ordinary sense of the word; that is they do not interrupt each other's course, or in the least degree modify each other's form. But where they cross, the particles of water are compelled to take part in two or many distinct motions, and the result may be that at the point of intersection the wave may rise or sink to the sum of the two waves if they coincide; or if they are opposed the water level may be normal and motionless while transmitting a rising and a falling wave in different directions. This is what is called *interference*, and the result is that in the case of sound two loud notes may result in silent intervals, and in the case of light two strong lights may produce darkness.

Both these effects are easily observed; the *beats* in musical sounds are due to interference. They may be heard in a double-wire piano if badly tuned, and very strongly in a concertina with what is called the *voix celeste*, which is produced by two reeds with a small difference, resulting in a rising and falling sound. Any door will exhibit the same effect in light, for if opened so that a beam of light passes through the

Digitized by Google

narrow opening at the back an apparent grating will be seen on the floor in the form of radial lines of light and shade. These are *diffraction* lines caused by the *interference* of the two rays of light reflected angularly through the slit from the two sides of the opening.

30. *Light reproduces all the phenomena,* and we are thus enabled to rise to the more occult principles of the generation and distribution of light by the study of sound, and the rough mechanical effects to be observed in pools of water, in stretched ropes, and in billiard balls. These enable us to see distinctly actions which unquestionably occur in the agents which produce and transmit light, but which cannot themselves be seen.

Light, like sound, has no specific existence; it is an undulatory action of energy set up in its generators and propagated, like sound, in rays and spherical waves, which in space are not light, nor even luminous; they only become light when transformed into a specific sensation in suitable organs—that is to say, *light is not a thing, but a perception of an action of energy.* The recognition of this is of great importance, because it involves the recognition of a fact by no means generally known, that *light can have no mechanical equivalent,* though the energy which produces the effect of light has such an equivalent. For this reason the same equivalent of energy expended by two sources of light, and delivering equal energy even to the very eye itself, may yet produce wholly different light effects, and therefore differ greatly in economy of light production.

MOSELEY'S IMPROVEMENTS ON BLAKE TRANSMITTERS.

It is well known that Blake's improvement on Edison's transmitter is the most approved of all telephone transmitters. It is not so widely known that there are three weak points in it which have hitherto been regarded as so inseparable from the Blake system that the most experienced telephone managers have for special purposes fallen back upon the original Edison and other instruments.

The reasons for this compulsory resort to anterior inventions are these:—

Firstly. There is no provision to exclude the fine dust incessantly floating about in every dry atmosphere, but which in all towns and cities is so profuse that it penetrates every cavity to which there is access through any crack or crevice, however fine. The electric current attracts this dust between and around the point of contact on the carbon button until in a few weeks at the least the articulation of the voice becomes so muffled and broken up by the transmitters that after many annoyances and interruptions from this unknown and perhaps unsuspected cause the assistance of an official inspector is required to remove the impediment.

Secondly. In addition to the dust impediment there is a process of wear and tear that destroys the particles of carbon which make contact with the platinum point at the end of the slender spring. If the instrument is delicately adjusted so as to respond to faint or distant sounds—which for the moment show off to the greatest advantage the beauty of the Blake invention—the destruction of the carbon particles is correspondingly more rapid. Hence, although the exclusion of dust lessens the evil, the natural action of the instrument produces a dirty ash, which causes similar annoyance and obstruction.

Thirdly. In consequence of the action just described, it is impossible to employ more than one battery cell where a louder voice or its transmission to long distances is required.

A remedy for this latter defect has been devised and patented by Mr. Moseley.

To remedy the first defect by the exclusion of dust the microphone action is enclosed in an air-tight box G (Fig. 1), the opening of which is closed by the diaphragm.

To remedy the second defect the carbon electrode A (Fig. 2) is made of a short cylindrical form, supported on the end of a stout brass wire spring, B, which is attached to a screw terminating in the milled head E.

The platinum electrode *c* is a small platinum head on the end of the light silver wire spring support D, ending in the milled head F.

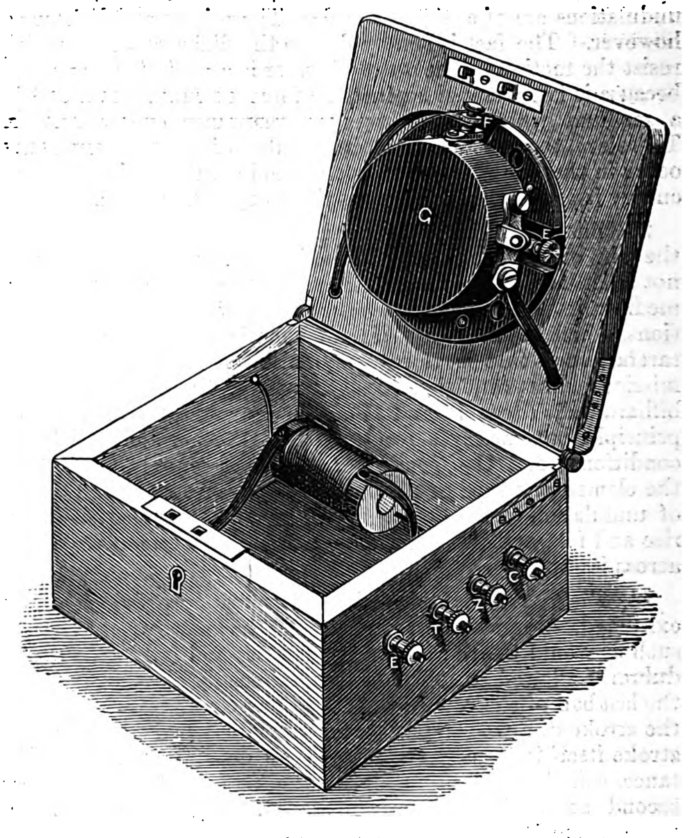

FIG. 1.—Moseley's Transmitter.

It will be seen, therefore, that when the transmitter produces any buzzing or confused sounds the terminals E and F may be instantly turned very slightly, which will at once present fresh material for the points of contact, and instead of keeping in order only one or two months, as alleged

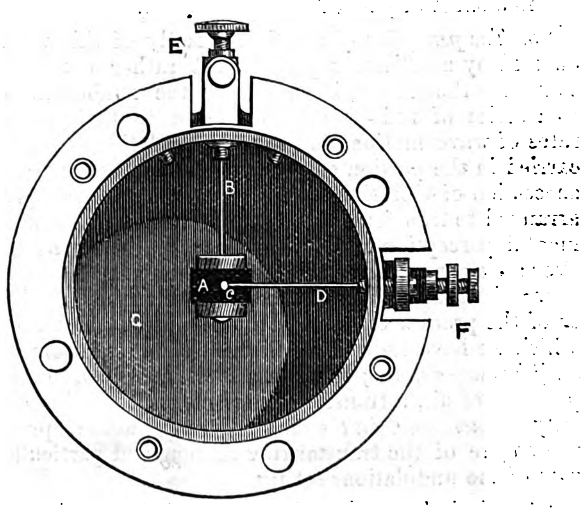

FIG. 2.—Moseley's Transmitter.

against the present instruments, there seems no reason why, with the improvements described, there should be any necessity for official attendance for ten or twenty years.

About seventeen years ago Mr. Moseley fitted up the Grand Hotel at Scarborough with nearly 400 electric bells and other apparatus.

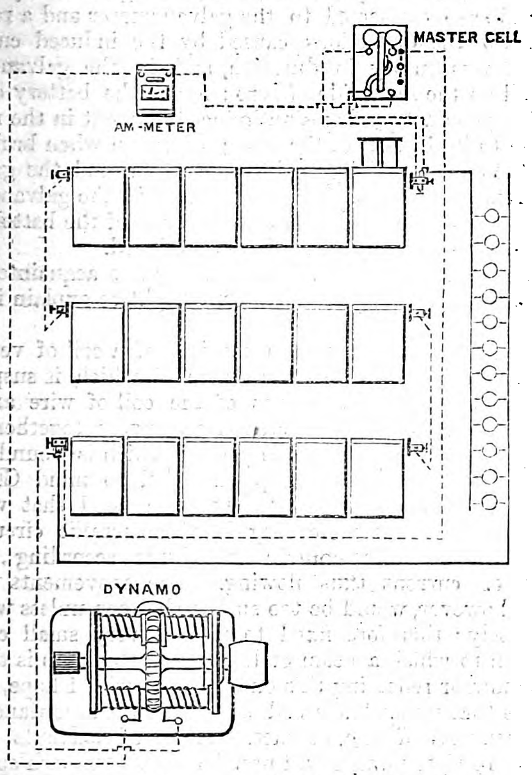
Digitized by Google

At that time he adopted various devices and precautions, which were, we believe, considered extreme and unnecessary; but we are not acquainted with such a large installation which has stood the test of time so successfully. This and many other important evidences of his conscientious foresight entitle any of his inventions to careful consideration.

As the invention above described is not patented in any other country than this, our readers abroad who are owners or licensees of the Blake transmitter patents are at liberty to adopt the ideas.

THE INSTALLATION AT COLCHESTER.

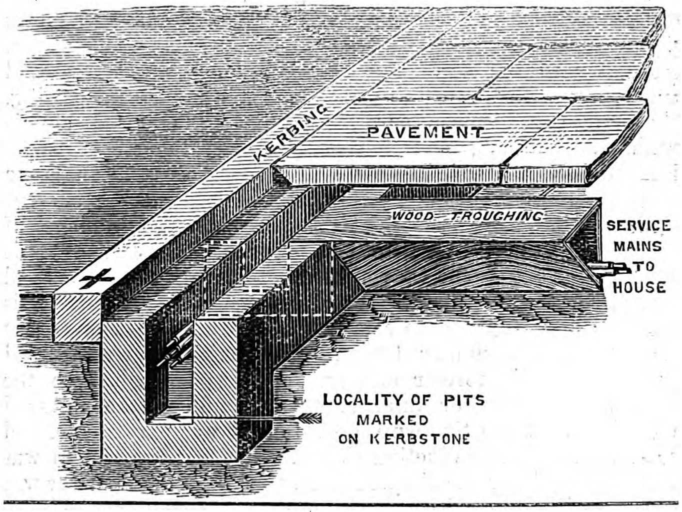
In the first portion of our report on the formal opening of this installation we referred to the meeting at the Town Hall and the reading of Mr. King's paper. At the conclusion of



Colchester Installation. Connections for charging the secondary batteries.

the paper the manager of the company, Mr. J. Offor, made a few remarks as to the estimated cost. Without entering into minute details, it is well known to electrical engineers that currents, where very great differences of potential exist, can be transmitted over comparatively small size wire. Mr. Offor pointed out that the system adopted at Colchester differed from the ordinary system used with incandescent lamps, inasmuch as the dynamos were high tension dynamos—Brush 40-lighters, in fact. The current generated by these dynamos was used to charge the secondary batteries in series, while the current was distributed from the secondary batteries in quantity. We must be somewhat emphatic in calling attention to this development of electric lighting industry, because such a strong opponent of secondary batteries as Mr. J. E. H. Gordon is compelled to admit that if secondary batteries can be made and so used they will be of great service. Now, at Colchester they are made and they are used. The charging mains from the dynamos, and the distributing mains from the lamps are placed in the same channels, easy of access, and so easy to inspect and test. We shall content ourselves just now, however, with describing the proceedings of the day, detailing the arrangements as we come to them. Mr. Offor went on to show that although the total cost of the batteries was roundly £4,000, and of the mains as used £1,500, there was a saving of from £2,000 to £3,000, for distributing the current to the 2,200 lamps would, with low tension current machines and lamps in multiple arc, have required mains that would have cost from £8,000 to £9,000. *The* one question in the minds and upon the tongues of many present was, what of the life of these batteries? If they have a fairly long life there can be no doubt as to the economy of such a system. This link in the chain can only be tested by time, and if we could venture to suggest a course to the company it would be that an exact history of these batteries be kept—that a rigid and continuous system of examination be maintained by men of repute unconnected with the company. It will pay the company to have these batteries watched with a keener watch than is kept upon the battlefield. After detailing the cost of plant, Mr. Offor referred to expenses and estimated receipts. The method of charging customers adopted at Colchester is ½d. per lamp per hour, and this is estimated to bring in a sufficient return to give a balance of between £1,000 and £2,000 on the right side, after paying all expenses and depreciating the plant.

A discussion was invited, and a number of questions were asked by the delegates from London, Brighton, Dudley, &c., present. The questions mostly related to expense and to



Colchester Installation. Street channelling with the mains.

length of life of plant. Our readers will have inferred that such questions could receive only general answers. Experience is absolutely necessary in order to obtain definite details as to lamps, batteries, &c.

At the end of the discussion the visitors went to the central station, and saw therein one of the battery rooms and the dynamo room. The paper of Mr. King has explained all this, but we may, perhaps, say that we understood that the Davey-Paxman (twenty horse-power nominal) engine had been constantly running for about two years without a hitch occurring at any time. The accompanying plan of the connection of the battery boxes will assist in explaining Mr. King's reference in the paper. The channels, a section of which is shown in the diagram, were opened for inspection—that is, a flagstone was raised, when it was seen that they were free from water, and there seems to be no doubt that the method adopted is satisfactory in this respect. All the charging and service mains we saw were lead-coated, upon the Berthaud-Borel system. One of the other battery stations was visited by many of the visitors, after which came luncheon. It is unnecessary for us to detail the speeches; they dealt with the special business of the day, the success of the lighting at Colchester, and generally with success to electric lighting. The company are certainly to be congratulated upon the arrangements at Colchester, and it is to be hoped that the future working will continue to prove that the somewhat sanguine estimate as to cost had not too roseate a hue.

VOLTA AND MAGNETO ELECTRIC INDUCTION.*

BY WILLOUGHBY SMITH, M.R.I.

The subject which I shall bring before your notice this evening is "Volta Electric and Magneto Electric Induction," and I propose to describe some of my experiments in connection with this phenomenon in electricity and magnetism, which was discovered, named, and for forty years fostered, within this very building, by our universally esteemed and beloved Michael Faraday.

It is now thirty years ago that Faraday gave me my first lesson in volta-electric induction, at the same time impressing upon me the fact that physical science must ever be progressive and corrective, and that he was always pleased to learn that his experiments had been repeated by others with a view to their verification or correction. In the remembrace of this I have felt encouraged in coming before you this evening.

Doubtless all present are familiar with the fact that about 1819 Professor Œrsted made a discovery which has done much to advance our knowledge with regard to electricity and magnetism. This discovery arose from a very simple experiment, but it is none the less valuable on that account. I will now repeat this experiment, as the result obtained will lead up to and enable you to better understand what I may show later on.

Here is a length of copper wire, from the top surface and centre of which projects a metal pin, having balanced on its point a magnet. The position of the steel is, as you perceive, parallel with the wire, and that position being north and south, it will thus remain until, by pressing down this spring, the length of copper wire is placed in metallic circuit with this battery; and you observe that the steel needle immediately has a tendency to place itself at right angles to the copper wire, remaining thus displaced until the current ceases to flow, when the needle again obeys the influence of terrestrial magnetism and returns to its former position. This was Œrsted's experiment which led to the discovery that all bodies possess the qualities of a magnet whilst a current is passing through them. From this fact Faraday conceived the idea that, if a similar length of copper wire were placed parallel with the former one, and close to it, each time the circuit was made or unmade there would be an induced current flowing in this wire, providing it was part of a closed metallic or other conducting circuit. The first experiment was not successful, for the simple reason that the galvanometer was not sufficiently sensitive to be visibly affected by the very small current induced in so short a length of wire as that with which he made the experiment; nor was he prepared to find that induced currents were of such momentary duration. But failures with Faraday were merely stepping stones to success; he repeated the experiments with spirals of insulated wire instead of wires parallel to each other and in a straight line, thus getting comparatively long lengths in close proximity; by these means he gained the object of his search, the result of which he called "Volta Electric Induction."

Through the kindness of Dr. Tyndall I have here the identical spirals which were made and used by Faraday on that memorable occasion. One of these Faraday connected in circuit with a galvanometer, and placed it on the top of the other spiral, through which intermittent currents from a battery were sent at fixed intervals. On making the battery circuit he noticed that the needle of the galvanometer was deflected in one direction, and on breaking the circuit the needle was again deflected, but in the opposite direction. Faraday saw in his mind's eye each particle of the circuit through which the current was passing acting as a centre of force emitting its lines far from it, yet each of these lines returning to its own source; he in consequence made a series of experiments by placing various substances in the path of the lines of force to ascertain whether they would in any way be affected or intercepted by the substances so placed. For instance, he found that they were sensibly affected by iron, but with copper no satisfactory effects were perceived, although he felt sure that copper did in some way influence them, but so imperceptibly that he was unable to detect it. It was this conviction and the doubt by Faraday of the result of his experiment with regard to copper which led me to experiment in this direction. My apparatus and its arrangements being somewhat different to Faraday's, I will more fully describe them. Here are two flat spirals of fine silk-covered copper wire, about twelve inches in diameter, suspended, spider web fashion, in separate frames; the two ends of each spiral being attached to terminals at the base of its own frame. These two spirals, which are marked respectively A and B, will now be placed a definite distance apart, and comparatively slow reversals from a battery of ten cells sent through spiral A. You will see the amount of the current induced in B by observing the deflection on the scale of the mirror reflecting galvanometer which is in circuit with that spiral. These inductive effects vary inversely as the square of the distance between the two spirals when parallel to each other; the induced current in B being proportional to the number of reversals of the battery current passing through spiral A, and also to the strength of the current passing. Spiral A is so connected that reversed currents from a battery can be passed through it at any desired speed; B is so connected to the galvanometer and a reverser as to show the deflections caused by the induced currents, which are momentary in duration, and in the galvanometer circuit all on the same side of zero; for, as the battery current on making contact produces an induced current in the reverse direction to itself, but in the same direction when broken, of course the one would neutralise the other, and the galvanometer remain unaffected. To obviate this, the galvanometer connections are reversed with each reversal of the battery current, and thus a steady deflection is produced.

Perhaps, for the information of those not acquainted with the construction of a galvanometer, I ought to explain it more fully.

The one I am about to use consists of a coil of very fine silk-covered copper wire, in the centre of which is suspended a very small magnet; the ends of the coil of wire and the ends of spiral B are connected respectively together, thus forming a metallic circuit, one part of which is wound into a coil and the other into this spiral. Call to mind Œrsted's experiment, and it will be readily understood that when a current of electricity is flowing in this metallic circuit the magnet will be influenced in magnitude according to the amount of current thus flowing. The movements of the magnet, however, would be too small to be seen unless watched very closely; therefore fixed to it is a very small concave mirror, on to which a beam of light from the lamp is thrown, and the mirror reflecting this on the scale will, I hope, enable all to see that somewhat broad beam move in accordance with the movements of the magnet. Reversed currents at the speed of 100 per minute will now be passed through spiral A, and you will observe that the induced currents in B give about 28 divisions on the scale of the galvanometer; we will note this on the black board. Now we place this plate of iron midway between the two spirals, and you observe the deflection on the scale is reduced to about one half, or in round numbers 15, showing clearly that the presence of the iron plate is in some way influencing the previous effects. We now remove the iron, when you see the deflection returns to its original amount, 28, and if I replace it by a similar sheet of copper the interposition does not alter the deflection. The results of this experiment are therefore as follows, viz:—

Speed	100 reversals per minute.
Induced current	28° deflection.
Iron interposed	15° "
Copper do.	28° "

I may here state that, up to this point, the results of my experiments confirm those of Faraday, that all dielectrics and diamagnetic metals appear in no way to interrupt or interfere with the lines of force.

Now let us repeat this experiment with the speed of the reversals increased ten times, or to 1,000 per minute; the spirals are in the same position as before, and the deflection is now about 86. I have already said that the current is in direct proportion to the speed of the reversals;

* Lecture delivered at the Royal Institution, June 6, 1884.

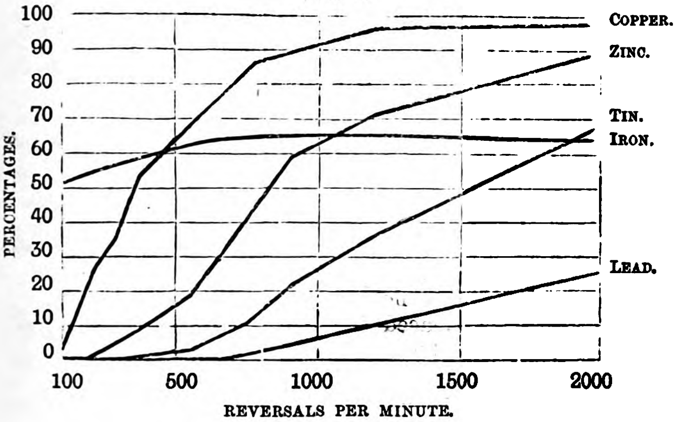
Digitized by Google

the battery and spirals remaining the same. It might therefore cause confusion were I not to explain that the deflection would be ten times as great as it was with the lower speed of reversals, but that the scale of the galvanometer not being sufficiently long to record this high deflection, we have what is termed "shunted" a part of the current; that is to say, between the two ends of the galvanometer coil we have inserted a length of copper wire, so that the current on arriving at one terminal of the coil divides, part going through the coil of the galvanometer, and the rest through the shunt; the two currents reunite at the other terminal of the galvanometer. By varying the resistance of the shunt, therefore, the desired amount of current can be sent through the galvanometer. In this case sufficient current passes to keep the beam of light just on the scale at about 86 divisions. We now interpose the sheet of iron as before, and you see the deflection falls again to about one half. We withdraw the iron and the deflection returns to its former amount, 86. We now interpose the copper, when the deflection, instead of remaining stationary, as in the former experiment, actually falls to 17. We now obtain the following results, viz. :—

Speed	1,000 reversals per minute.
Induced current...	86° deflections.
Iron interposed ...	40° „
Copper	17° „

Now the question arose, why does copper, at the low speed of the reversals, apparently have no effect, while at the higher speed it plays so important a part in intercepting the lines of

Fig. 1.



force? The only solution of the phenomenon which suggested itself to me was, that the lines of force have first to polarise the molecules of substances placed in their path before they can pass through them, and in this process time is a very important element to be considered. For instance, at the slow speed there is sufficient time between the reversals for the copper to polarise before the next reversal takes place; whereas at the high speed the copper plate is unable to fully polarise before the next reversal arrives, and then the two induced effects partly blend, and being opposite in direction tend to cancel each other. Now, if this really be the case, the higher the speed the less should be the proportional deflection when experimenting with copper. The time at our disposal this evening will not allow of accurate measurements, or of other substances being experimented upon, but careful and reliable measurements have been made, the results of which are shown (Fig. 1).

It will be seen by reference to these results that the percentage of inductive energy intercepted does not increase for different speeds of the reverser in the same rate with different metals, the increase with iron being very slight, whilst with copper the induced current set up is so long in duration that when the speed of the reverser is at all rapid, the current not having time to exhaust itself before the galvanometer is reversed, tends to produce a lower deflection. If the speed of the reverser is further increased, the induced current is received on the opposite terminal of the galvanometer, and thus a negative result is obtained.

My next object was to verify, if possible, by a different system of experiment, the correctness of this theory, and I could think of no better arrangements than those used by Faraday in some of his experiments on magneto-electric induction. I was not, however, encouraged to proceed in that direction; for, if my theory were correct, the results published by Faraday could not be so, and knowing what a careful experimenter he was I could not doubt but that he was right. After long and careful thought on the subject, I ventured, however, to repeat some of his experiments, and I will again repeat them before you presently.

About sixty years ago Arago made the discovery in electrical science that if a plate of copper be revolved close to a magnetic needle, or magnet suspended in such a way that the latter may rotate in a plane parallel to the former, the magnet tends to follow the motion of the plate; or, if the magnet be revolved, the plate tends to follow its motion. This simple apparatus will better illustrate the experiment. Here is a copper plate one-tenth of an inch thick and 7½in. in diameter, fixed to a vertical spindle, and enclosed in a wooden case having a glass cover; beneath the copper plate is a small grooved pulley, around which passes an endless band, the band also passing round this horizontal wheel, to which a handle is fixed, so that it may be conveniently revolved. A small brass disc is here provided, in the centre of which is fixed a pointed steel pin, and on this pin is balanced a steel magnet. I will place this on the glass cover over the centre of the copper plate. Now, if the copper plate be made to revolve, you will see that the magnet will revolve also, in the direction of the copper disc. There it goes! No doubt you observed how sluggish its movements were at first, and that it was some time before it followed the movement of the disc. This was owing to the attraction of the earth's magnetism on the magnet, which held it in bondage until the speed of the disc was sufficient to overcome its attraction; then, once released, how merrily it appeared to obey the influence of a superior power. The disc now being at rest, the needle has returned into bondage; but if I judiciously use the influence of this magnet to partially neutralise the influence of the earth's attraction, you will observe how much more quickly it obeys the influence of the mysterious power of the revolving disc. There it goes! Apparently more merrily than before. Were I lecturing on moral philosophy, I certainly should make use of the similes which might be drawn with advantage from experiments with this simple instrument. But my subject being of a different nature, I will resume without further digression.

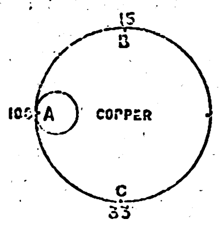
If the order were reversed and the magnet removed, the copper disc would act in the same way as the magnet has just done. This is the phenomenon discovered by Arago, who also asserted that the effect takes place, not only with all metals, but with all substances. On this latter point there has always been a difference of opinion between experimenters who have endeavoured to verify Arago's statement. As far as my experiments have gone, I have only obtained reliable results from good conductors of electricity; but I believe that, theoretically, Arago is right, for as all substances are, in a certain degree, conductors of electricity, it I think necessarily follows that we only want sufficiently sensitive instruments to develop the phenomenon, as Arago asserts, in every substance. It has been stated that all substances when subjected to a sufficiently strong magnetic force are found to give indications of polarity, and also, when magnetic force acts on any medium, whether magnetic, diamagnetic, or neutral, it produces within it a phenomenon called magneto-induction. If this be the case, it materially strengthens the correctness of Arago's assertion.

Arago's discovery that copper, a non-magnetic metal, was influenced by a rotating magnet, or that a magnet was in the same way affected by a rotating disc of copper, was looked upon at the time as a new and remarkable phenomenon in induced magnetism by philosophers both in England and other countries; but it was Faraday who, by the assistance of his knowledge of the evolution of electricity from magnetism, gave the true solution by proving it to be the effects of

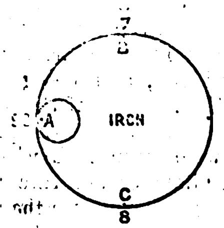
Digitized by Google

electrical currents induced in the disc on account of its motion in a magnetic field. He not only proved by simple experiments the correct interpretation of the phenomenon, but he saw the way to making the discovery of Arago a new source of electricity, not despairing by the aid of his knowledge of terrestrial magneto-induction of being able to construct a new magneto-electric machine. For this purpose he arranged an apparatus, similar to the one I have here, which is simply a permanent magnet so fixed that discs of metal or other substances can be rotated between its poles. Two wires leading one from each terminal of a galvanometer were applied to any desired part of the revolving disc, and the deflections on the galvanometer noted. The first experiments were made with a very large compound permanent magnet, and with what would now be termed a quantity astatic galvanometer. His discs of metal were 12in. in diameter, and about one-fifth of an inch in thickness, fixed upon a brass axis. He experienced difficulty in making contact between the terminals of the galvanometer and the edge and other parts of the revolving disc, as also in maintaining uniform velocity of rotation. With a much smaller magnet and a more sensitive galvanometer the results were more striking. Thus, with his accustomed simplicity, he demonstrated the production of a permanent current of electricity from an ordinary magnet, at the same time asserting that with powerful magnets and rapid rotation of a copper disc very strong currents would be produced. What a wonderful lesson this apparently simple machine teaches, for it is able to exert the power that has its origin within itself on external matter without in any way exhausting or diminishing that power!

The apparatus that I employed for my experiments is the same that I shall use this evening. On this stand is fixed an electro-magnet, the poles of which are so placed that the rim of the disc under experiment can be freely revolved between them. The cores of the electro-magnet are 1·75 inch in diameter, and are wound with twelve layers of silk-covered copper wire of high conductivity, ·028 of an inch in diameter, each layer having sixty-one turns; each core has 732 turns, making a total of 1,464 turns on the two poles. The total resistance of the wire is 13·75 ohms, and through this flows the current from twelve Leclanché cells. The same galvanometer is used as with the other experiments, being brought in circuit with the disc by means of the axis on which the disc revolves, and a metal brush which forms a rubbing contact on the rim of the disc. This, working on a fixed centre, can be readily shifted to any part of the circumference of the revolving disc. The disc is revolved by this cone-shaped pulley, worked lathe fashion, connected by an endless band to a small grooved pulley fixed on the same axis as the metal disc. We will now make a few experiments with the copper disc, which is now revolving at the speed of one thousand revolutions per minute, and the connections are so made that the current will be taken from the rim of the disc just as it passes between the poles of the magnet. On pressing this spring the circuit is complete, and you observe the effect of the current on the scale of the galvanometer; it is about 100 divisions. We will now remove the contact to about one fourth of the diameter of the disc or top position, so that the current will be taken at that distance from the poles of the magnet as the disc is approaching the poles; now, on completing the circuit, you observe the deflection is reduced to about fifteen divisions. The contact will now be removed to the opposite side, or bottom position of the disc, so that the current will be taken at the same distance from the poles, but after that part of the disc has just passed between them; on completing the circuit you see the deflection has increased to thirty-three divisions. Let us note these results as follows:—



We will now replace the copper disc with one of iron, and repeat precisely the same experiment. We find that the current from position A is so great that it is necessary to insert a resistance of 500 ohms in the circuit to bring the beam of light on to the galvanometer scale; as before shown, by means of inserted resistance we can obtain any desired deflection. It is now about 98 divisions, and that we will take as the right measure for position A. We take B or top side position, and you observe that the deflection is only 7 divisions; the connection is now placed at position C or bottom side, and we get but very little more current, as the deflection is only increased by one division. The results with iron may therefore be noted as follows:—



500 ohms in circuit.

If we compare the results of these experiments with those obtained with the same metals in volta-electric induction, we see that iron remains fairly uniform in its results in both cases, but that copper behaves differently. You must not, please, take the figures given as being absolutely correct, the experiments having been somewhat hurriedly made, and merely given with the view of enabling you to understand the results of carefully made experiments with various metals. These results are graphically shown in Fig. 2.

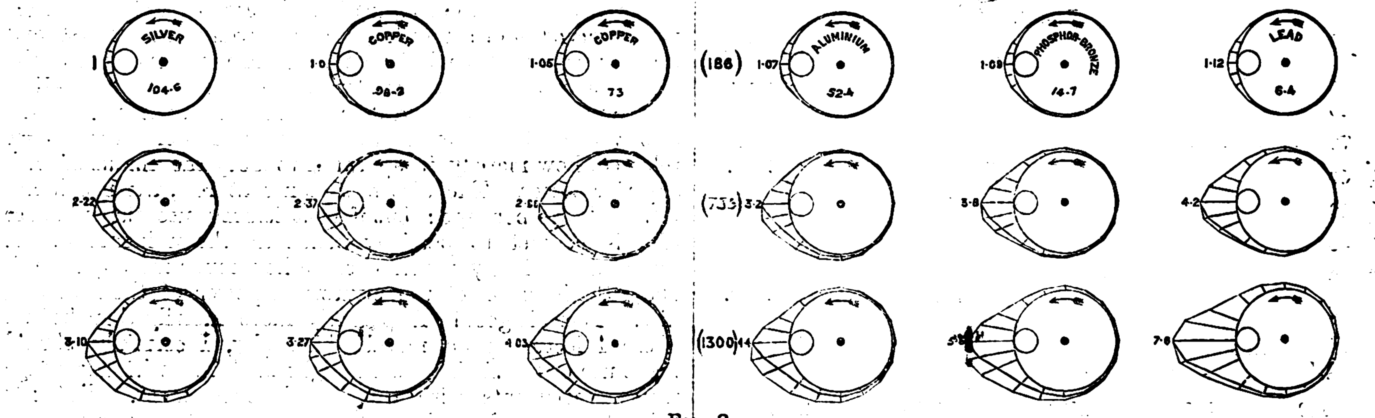


Fig. 2.

and, as the measurements are to scale, they can be directly compared with each other. The large circles represent the revolving discs, the small ones show the position of the poles

of the electro-magnet, and the arrows the direction of rotation. The boundary lines show the electromotive force at every point round the revolving disc; thus in every case the strongest point is, as might be expected, directly in front of the poles of the exciting magnet, the strength gradually fading from thence on either side. The blue portions show the excess of inductive effect there produced, relatively to a point equidistant from the magnetic poles, but on the other side. If the current set up in the metal simply depended upon the intensity of that part of the magnetic field through which the metal was passing, then equidistant points on either side of the magnetic poles should produce equal deflections, because the magnetic intensity is equal; on inspecting the diagrams, however, it appears as if a very sluggish inductive effect were produced in the diamagnetic metals of high conductivity, the sluggishness increasing with the conductivity of the metal, as though the atoms took a comparatively long time to accommodate themselves to the changes in the magnetic field through which they were passing. This, I think, confirms the theory I have ventured to advance with respect to copper while under the influence of induction.

is but very little of what I have termed "drag" in those metals. The consequence of this is that with iron the amount of current is nearly in direct proportion to the speed of the disc, whereas with copper the increase is very small, the current produced by the two metals being as 1 to 7, at a speed of about 1,300 revolutions per minute. The higher the specific conductivity of the diamagnetic metal the greater the "drag," and consequently the less the current at the poles, this being more manifest at the high speeds, which does not, however, agree with the results obtained by Faraday, for he found that the currents were proportionate in strength to the conducting power of the bodies experimented with; or, in other words, that the higher the conductivity the greater the current; whereas I find the reverse to be the case, as shown on the diagram before you.

Faraday also obtained much better results from copper than from iron, and thus he recommended copper for his new magneto-electric machine. Here, again, my results do not agree with his, for I find that iron gives much better results than copper, as shown on the diagram, and also that iron has the great advantage that the current increases almost in direct

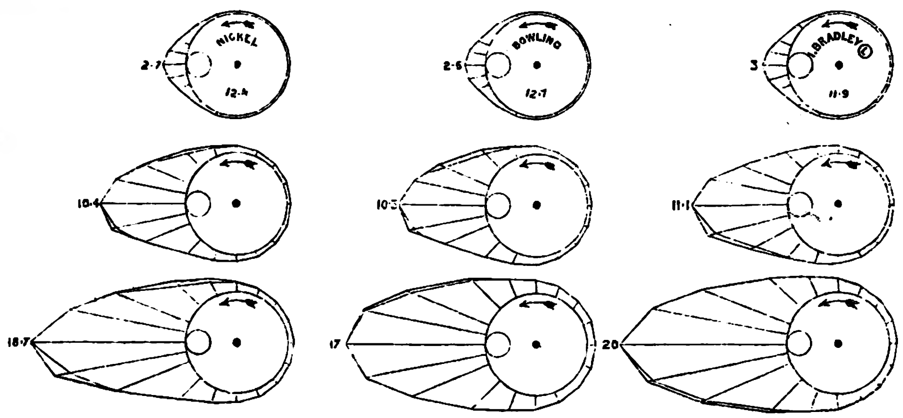

Fig. 3.

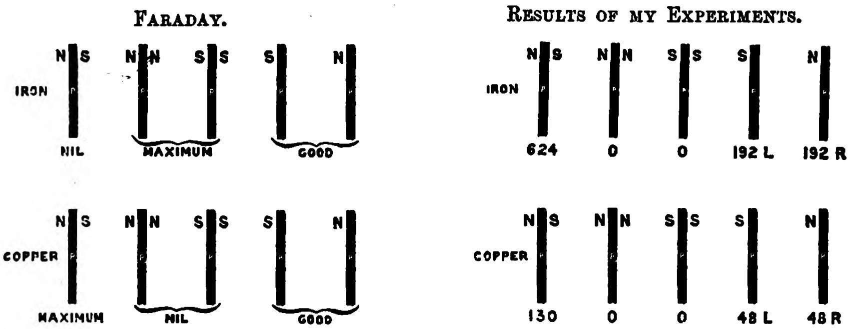

Fig. 4.

If, as in the case of volta-electric induction, the lines of force are generated too quickly, or, as in the case of magneto-electric induction, the diamagnetic body passes too quickly through the magnetic field, the atoms of the substance in each case have not time to polarise with sufficient rapidity to radiate in the same time or place as when influenced more slowly by this force. This would account for the apparent interruption of the lines of force by the copper plate in the volta-electric experiments, and also for the "drag" or retardation on the disc of the same metal as shown by the blue colour in the diagram whilst part of it is passing quickly through a magnetic field. That being the case, it is easy to perceive that a speed of the copper disc might be attained, when the current would be *nil*, through the atoms being unable to polarise in the allotted time. Not so with magnetic metals as iron or nickel, in each of which the atoms appear to be very susceptible to magnetic influences, and to polarise very quickly, as shown by the way in which part of the disc is affected just before entering between the poles, as shown in the blue colour in the diagram (Fig. 3).

The atoms must as quickly depolarise, as you perceive there

proportion to the speed, whereas copper does not; in fact, as already stated, a speed might be obtained at which copper would give *no* current.

Faraday in summing up the results of his experiments on Arago's phenomenon says, "Nothing can be more clear, therefore, than that with iron and bodies admitting of ordinary magnetic induction opposite poles on opposite sides of the edge of the plate neutralise each other's effects, while similar poles exalt the action. But with copper and substances not sensible to ordinary magnetic impressions *similar* poles on opposite sides of the plate neutralise each other, and opposite poles exalt the action." Perhaps you will more readily grasp the subject by reference to the diagram (Fig. 4), in which P represents the plates of metal, and the other letters the respective poles of the magnet and their position. Here again it will be seen that the results obtained by me are opposed to those given by Faraday. I have given the actual figures obtained in my experiments, and it will be seen that the only difference between the metals copper and iron is that iron gives the higher current of the two, as it has done in all my experiments.

Digitized by Google

I have no doubt but that we should be able to get approximately near for all practical purposes to the relative conductivity of metal by revolving discs of the metal under test in a magnetic field, and measuring the mount of current between the poles or the amount of "drag." The results given (Fig. 5) show how suitable the method also is for obtaining the saturation point of the cores of electro magnets, whether of different qualities of iron or other magnetic metals.

Very recently an Electrical Congress held in Paris agreed to a universal system of electrical units. I believe the value of some of the units to be adopted was determined by passing masses of metal at varying velocity through a magnetic field of uniform intensity and noting the amount of current so produced. I understand that the results obtained by different experimenters did not agree, and from what I have shown you this evening you will readily understand the reason of the discrepancy. To obtain accurate results the influence of what I have called "drag" must certainly be taken into the calculations as an important factor.

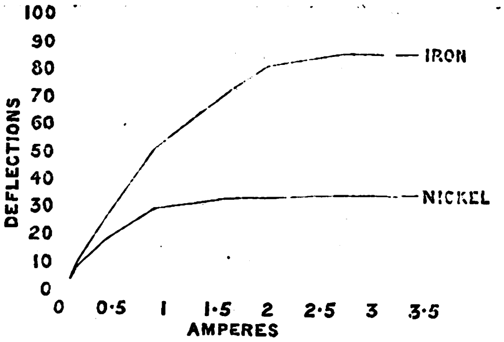

Fig. 5.

There are other matters to which I attach importance connected with the experiments I have endeavoured to make clear to you, especially with those on magneto-electric induction, which I publish for the first time this evening; but of the many good rules of this Institution there is one which does not allow me to tax your patience for more than one hour, and as I have already exhausted that time I must not detain you longer except to thank you, which I do most sincerely, for the kind attention you have given to my humble endeavours to advance our knowledge of "Volta-Electric and Magneto-Electric Induction."

LEGAL.

The Board of Works for the Wandsworth District v. the United Telephone Company (Limited).

This case came before the Master of the Rolls and Lords Justices Bowen and Fry, in the Court of Appeal, on the 12th and 13th inst. Mr. Webster, Q.C., Mr. Cozens-Hardy, Q.C., and Mr. Moulton were for the appellants; Mr. Philbrick, Q.C., Mr. T. L. Wilkinson, and Mr. Lane were for the respondents. It was an action by the Wandsworth Board of Works against the United Telephone Company for erecting telephone wires over the highways of that district, and the complaint was that the company had without the consent of the Board placed wires over, along, and across certain of the streets and highways for the purpose of telegraphic or telephonic communication, the same being alleged to be dangerous to persons using the streets, and the Board claimed an injunction against placing any wires over streets under their control without their consent. The company denied that the wires were dangerous to the public, and that was the real issue in the case. This was the first case which had come before the courts to raise the question whether a telephone company has a right against the will of the local authority to place wires across the streets. The case was tried on the 8th of May, before Mr. Justice Stephen without a jury, and the learned judge gave his decision against the company. The case for the Board was put on three grounds—first, they contended that the company were subject to the provisions of the Telegraph Act of 1863, and were as such forbidden to place a telegraph over or along or across a street or public road, except with the consent of the body having a control of it; secondly, that the Board, as owners of the soil, had an absolute right to prevent the company from suspending wires over their road, upon the principle that the air above the road was as much theirs as the road itself; and, thirdly, that the overhead wires were in fact dangerous to persons using the road, and therefore a nuisance. Upon the first point the argument was that, as it had been held in the Attorney-General *v.* the Edison Telephone Company that a telephonic message is a telegram, therefore the Telephone Company is a telegraph company within the Act of 1869, and therefore a company under the Act of 1863 and so within the 12th section of that Act. But the learned judge held that as the company were only licensed by the Postmaster-General to carry on the telephone business, from which otherwise they would be restrained by the Act of 1869, and had none of the powers of a company under the Act of 1863, therefore the argument for the Board on this first point failed. Then as to the second point, the learned judge referred to the case of Coverdale *v.* Charlton, which went to the Court of Appeal, and was recognised in a case of St. George's, Southwark, in the Rolls, in which it was held that the rights of the local authority extended not only to the surface of the highway, but to a reasonable depth below it—that is, to such an extent as necessary to its safety and stability, and he said, "It seems to me that the present case must be decided upon the principle there laid down. The case does not directly decide anything as to the extent of a street upwards; it only limits its extent downwards. It does it, however, upon grounds which seem to me to apply equally in each direction. If it can be shown that the management and care of the street require some degree of control over the air immediately above it, as well as over the ground immediately below it, it seems to follow that the vesting of the street itself in the District Board must involve property in part of the air above the surface of the street as well as property in part of the ground below it. Now, it is self-evident that in many cases the air immediately above the street may be dealt with in such a manner as to affect the safety and comfort of the street, as, for instance, if an electric wire passes across the street at such a height as to interfere with the traffic. Such a case might be dealt with as a nuisance at common law, but might it not, apart from the law of nuisance, be treated as a trespass to the property of the Board? So long as the wire is at a height which actually interferes with the traffic the question is of no practical importance, but when it is suspended at such a height and in such a manner that it does not interfere with the traffic of the street, except possibly in some extraordinary case, the question becomes one of great importance;" and in order to illustrate this the learned judge went on to give his opinion as to the third ground on which the Board based their claim. "This ground," he said, "is that the overhead wire is a nuisance to the highway, and that as such they are entitled to have it removed, apart from the question of property. This it was agreed was a pure question of fact. The evidence given on both sides appeared to me to show that the wire in question is nearly new, and that it was properly taken care of and had been lately examined and found to be in perfect condition, and likely to last for many, or, at all events, for several years, without becoming perceptibly weaker than it now is. It causes, and in the common course of things is likely to cause, no perceptible danger to the public, though it is no doubt possible that a violent storm might blow it down, just as it might blow down the chimneys to which it is in most places attached. There was, however, evidence that on two occasions wires of a similar character had, in violent storms, been blown down in such a manner as to become a source of some danger to persons or carriages passing along the highway. Upon the whole, though I cannot say that absolutely no danger arises from the position of the wire, I do not think that apart from the question of trespass it would form an indictable nuisance." That being so, the learned judge went on to say that in his view the question upon which the case must turn was whether the street vested in the Board extended to such a height above the ground that the suspension of the wire over it was a trespass which entitled them to an injunction. He was, he said, first of opinion that it was not so, but had come to the conclusion that it was. "Upon the best consideration," he said, "it seemed to him that Parliament intended to give to the District Board proprietary rights over the street, including in that a certain space upwards as well as downwards, in order that the Board might form a judgment as to the expediency on public grounds of permitting or refusing to permit various acts which, without being actual nuisances in such a sense as to be indictable, might, nevertheless, be regarded as undesirable innovations. (He put the case of a bridge connecting two houses on different sides of the street.) So with regard to telegraph or telephone wires, a single wire might be no nuisance, yet if no one had a definite right in the interest of the public to object to its erection such wires might be multiplied to any extent, and might collectively constitute a very appreciable nuisance." "I do not," said the learned judge, "suppose that the Legislature thought of this when the streets were vested in the District Boards, yet I think that the object of the enactment was to vest the Boards with the character of owners, in order that they might use for the public convenience rights which a prudent private owner would use in his own interest and in the interests of his tenants; and I am much strengthened in this view by the provisions of the Telegraph Act of 1863, for if private persons had at common law a right to suspend wires over the streets, subject only to the general law of nuisance, I do not see why the Legislature should in express words have authorised telegraph companies to do so, or why they should have required them to obtain the consent of the public body having control of the street. If they already possessed the power at common law there was no need to give it, though it might be necessary to qualify it." For these reasons the learned judge gave judgment in favour of the Board, though as he did not think the wire caused at present any appreciable danger to the public, and there was certain to be an appeal, he delayed granting the injunction. The company now appealed from that decision.

Mr. Webster, Q.C. (with Mr. Cozens-Hardy, Q.C., and Mr. Moulton) appeared on behalf of the company, and argued in support of the appeal. There were, he said, no posts in the street, and the wires were fixed up

Digitized by Google

overhead, 30ft. above the street, at such a height, as was admitted, as not to interfere with the traffic in the street, even in the case of a fire escape. [Lord Justice Fry: Any existing fire escape; future ones might be higher.] The more recent fire escapes are lower than the former ones. [Lord Justice Fry: The learned judge decided not upon the ground of nuisance, but upon the ground of a proprietary right in the column of air over the highways?] Yes. [Lord Justice Bowen: It may be that we may have to decide an intermediate point, not that the Board are absolute owners of the column of air over the street, but that they are so far the owners, or are the owners to such an extent as may be necessary to secure the safety of the passengers or prevent danger to them.] That is not denied; but it is submitted that the point does not here practically arise, because there was nothing in the wires to cause nuisance or danger to the public. [Lord Justice Bowen: The Board have the soil vested in them to such a depth beneath the street as necessary to protect the safety of the road, and so they may have a similar right in the air over the street.] That is not disputed; but it is submitted that the wires here cause no danger to the public. [Lord Justice Fry: But it appeared that there was a possible danger from which the public ought to be protected.] That might be sufficient, and it is admitted that the Board are so far owners as to be entitled to protect the public from danger at any height above the streets, and would have sufficient powers to protect all street traffic, and prevent anything which if it were to occur would be a nuisance or a danger to the public. This is freely admitted, but it is submitted that the question here does not arise, as there is no possible reasonable apprehension of danger to the public from the use of these wires at such a height overhead. As to the doctrine *cujus est solum ejus est usque ad cœlum*, that whoever is the owner of the soil is the owner of the air over it up to the heavens, that legal maxim has no application here, because the Board are not absolute owners of the soil and have no rights either over or under the ground, except so far as necessary for the safety and the interests of the public. [The Master of the Rolls: They do not claim to be absolute owners.] No; if they had alleged it it would have been denied and disproved. They have only such rights as pertain to them as guardians of the highways. The wires are so high overhead, being fixed to the houses, never less than 30ft. above the streets, as to cause no danger to the public. [Lord Justice Bowen: That is a question of fact.] It is so, and it was virtually decided by the learned judge in favour of the company. [The Master of the Rolls: The others are questions of law.] They are so, and they are to be argued, and he proceeded to argue them accordingly, reading the judgment and commenting upon it, and reading the passages as to the right of the Board to the soil beneath the street so far as necessary for the safety of the highway. [Lord Justice Fry asked whether he would admit that this would entitle them to prevent excavations at any depth which would endanger the highway?] No. [Lord Justice Fry: Why not? Is there not a right to the extent necessary to protect the highway?] The soil beneath the street is not absolutely vested in the Board, but only the street, and the Board have only a right to protect it. [Lord Justice Fry: The Metropolitan Local Management Act vests the streets in the Boards.] Not the soil, only the street and the pavements and materials of the roadways; it does not mean any right of ownership in the soil. The Act expressly enumerates pavements, stones, &c. [Lord Justice Bowen: That merely does not convey the soil.] It surely rather excludes it. [Lord Justice Fry: No, for it means loose stones, &c.] And that is all it is intended to vest in the Board. That being so they have no right of property in the soil, and have only a power to protect the highway from actual danger. Here there is no such danger, and so they have no right to interfere. [The Master of the Rolls: The Act does more than give the Boards powers of control, it vests the streets and highways in the Boards, that is to the depth ordinarily necessary for the safety of the highways.] It is submitted that it is not so, and that the soil of the street is not vested in the Boards. The Boards had only power to prevent danger to the public, and here the learned judge himself had found that there was no danger. Yet in his judgment he had very much mixed up the right of property with the power to prevent danger. [Lord Justice Bowen: If there is a right of property in the air over the street it is not material whether there is a danger it is desirable to prevent.] Yet the learned judge rather mixes them up in the end of his judgment. [Lord Justice Fry: He a little departs from the ground of property, no doubt, but is there not a basis of good sense in the argument in favour of some power in the public body to prevent danger?] No doubt, where any danger arises, but here there is none. [The Master of the Rolls: The learned judge puts the case of a bridge over a street, but a bridge over a highway, as the Rialto at Venice over the canal, may endure for ages; only the learned judge says if one man is allowed to put a bridge between two houses then some one else may make another, and so turn a street into a covered way or tunnel.] Here, however, in the conclusion of his judgment, the learned judge declared that there was no "appreciable actual danger" in the wires, and so it is clear that his judgment, at least on his reasoning, can only be supported on the ground of property in the air overhead, and that, it is submitted, is not sustainable. [Lord Justice Bowen: Is there not a proprietary interest in the Board so far as necessary for the public welfare?] That need not be disputed. [Lord Justice Fry: If so, does it not conclude this case?] No, for there is no present actual danger. [Lord Justice Fry: But if there is such a proprietary interest, surely it would extend not only to such wires as cause actual present danger but also to such possible dangers as may be apprehended?] It is not admitted to that extent; nor did the cases cited go to that extent.

Mr. Cozens-Hardy, Q.C., followed on the same side, entering into the authorities, and arguing that they had not gone to the extent of vesting in the Boards any property in the soil under the streets. With reference to the theory of the right of an owner of land to a column of air over it there was much curious discussion, and as a test the case of a balloon was put, whether its going in the air over a man's land was a trespass, and conflicting *dicta* were cited about it.

Mr. Wilkinson (with Mr. Philbrick, Q.C., and Mr. Lane) appeared for the Board, and argued in support of the judgment, contending that they had a right in the soil of the street and the air over it, which was infringed by the fixing up of the telephone wires.

The case was here adjourned to the following day, the 13th inst., when their lordships gave judgment, allowing the appeal.

Judgment.

The Master of the Rolls said that the solution of the question depended upon the construction of the Act of Parliament which gave powers to the Local Board. Whatever those powers might be, there could be no doubt that if it had been shown that the wire was a nuisance and interfered with the proper uses of the street as a street, then the plaintiffs would be entitled to an injunction, whether the wire was within the street or not. But the learned judge had found that there was no appreciable danger from the wire. It could not be said that the wire interfered with the traffic of the street, the word "street" being used in its ordinary acceptation as to the width between houses; and therefore there was no ground on which the claim for an injunction could be maintained, unless the mere fact of putting up the wire was a trespass upon the property of the Local Board. His lordship understood the learned judge to have decided upon the ground that there was such a trespass, and that the plaintiffs were entitled to an injunction whether they were injured or not. The Local Board had no rights except under the Metropolis Management Act, 1855. That Act had been considered in Rolls *v.* the Vestry of St. George the Martyr, Southwark, ("Law Reports," 14 Ch. D., p. 785). The Act says that all "streets" shall "vest in and be under the management and control of the District Board." The same question arose in that case as in the one in question as to the meaning of the words "vest" and "street." The meaning of these words had been considered by the Court of Appeal in the case of Coverdale *v.* Charlton. His lordship's view in that case was that the word "vest" passed the property in whatever was the subject matter to be dealt with, so as to enable any one other than the public was concerned, *i.e.*, without infringing their duty to keep the street as a street. It was not necessary in that case to decide as to the duration of the right, but in a subsequent case the Court of Appeal decided that the right only existed as long as the thing was a street. Agreeing absolutely with that, it seemed to his lordship that his opinion in the case of Coverdale *v.* Charlton was that property in a street passed to the Local Board, and that if the thing ceases to be a street the property ceased also. The question then arose in that case as to the meaning of the word "street." It was suggested that the word only meant a right of way, or the mere surface. But the Court went further than that, and held that the street went below the real surface. In his lordship's opinion that was the basis of the judgment. The judgment of Lord Bramwell seemed to show that with regard to depth, the property passed in what Lord Justice Fry had called "the area of ordinary user," that is such user as is needed for the ordinary works done in a street. The judgments of Lord Justice Cotton and himself did not differ, and the groundwork of the judgment of the Court, as to depth at all events, was that in the statute in question, in which the word "street" is used, and the word "land" was not used, you must give to the word "street" the meaning popular at the date of the Act, and that as regarded depth, "street" meant that which contains the area of ordinary user existing at the date of the Act. That judgment gave the principle to be applied in the present case, where it was to be applied to something above the surface. He was not going to question that which had been laid down by Lord Coke, that when a man has conveyed "land" in terms, every right is passed which is covered by that land down to the centre of the earth, and *usque ad cœlum*. That was by the common law of England. But it does not follow that the same would be conveyed where the grant is by the word "street." Supposing it did, yet the question was as to what was the meaning in the statute in question, which dealt with "streets," of which the public had the use, and with people who, for the benefit of the public, had the property in and the guardianship of these streets. It seemed to his lordship logically to follow that those who came to the conclusion that in this statute the word "street" included that which below the surface is within the ordinary area of user of the street, must also hold that the same rule applies to that which is above the surface, and that it includes that area of air which is the area of ordinary user of the street as a street. His lordship doubted very much whether the height was confined to the present height of a fire escape, and he would not give a measure of height. Applying that rule to the wires in question, it could not be said that to walk along the tops of the chimneys to which the wires were affixed was an ordinary user of the street as a street. The statute did not pass property over the street, but only in the street. Therefore, no property passed in that part of the air in which the wires were placed, which, in ordinary language, were wires placed over and not in a street. Mr. Justice Stephen had construed the word "street" too largely, and could not grant an injunction on the mere ground that there was a trespass. As to the argument that the wire could not be put up without the leave of the Board, it was an endeavour to apply the interpretation of a particular phrase in a statute to a different phrase in another statute which was incorporated with the first. His lordship was of opinion that the case was within the principle laid down in Coverdale *v.* Charlton, and that the wires were not placed upon property of the plaintiffs so as to enable an injunction to be granted on the ground of trespass.

Lord Justice Bowen gave judgment to the same effect.

Lord Justice Fry said that Mr. Justice Stephen, although he had proceeded upon right lines, had erred in applying the case of Coverdale *v.* Charlton, and intending to follow the case, extended the area vested in the Board so as to make it include the area of possible interference.

COMPANIES' MEETINGS.

The Faure Electric Accumulator Company (Limited).

An extraordinary general meeting of the shareholders of the above Company was held at the City Terminus Hotel, Cannon-street, on Thursday last, Mr. Harcourt-Turner in the chair.

The SECRETARY having read the notice calling the meeting,

The CHAIRMAN said that before proceeding to the business calling the shareholders together they would naturally expect to hear something from the Committee of Inquiry as to what they had done since the last meeting. First and foremost, he had to tell the meeting that they had changed the solicitors of the Company. They took that step because it was felt that as the inquiry went on questions might be raised as to the validity of some of the contracts, of which there had been many, that had been entered into, and that it might be necessary to take steps against M. Philippart; and a respectable firm like Messrs. Campbell and Co., who had drawn up those contracts, and who represented M. Philippart as well, could not be asked to blow hot and cold with the same breath. It was therefore thought better for all parties concerned that those gentlemen should relinquish the post, and that others should be appointed in their place. It was a subject of most anxious consideration with the Board for some time, they having the names of several eminent firms of solicitors before them; but ultimately it was decided to appoint Mr. Snell, of the firm of Messrs. Snell, Son, and Greenip, a step which he trusted would meet with the approval of the shareholders. Another thing the committee had had to do was this, they had had certain claims made upon them, and, as the meeting knew, there was no money to meet them, and rather than call the shareholders together to give them power to make a call to pay those claims, and so wash their dirty linen in public, they had put their hands into their own pockets and made the payments, and thus kept the affair going. He need not tell the meeting that they had not to took very far into the affairs of the company before they found that M. Philippart was certainly a very great debtor to the Company. They at once wrote to the syndic at Paris who was managing his bankrupt affairs, informed him what claims the Company had, and after doing that they placed their affairs in the hands of an *avoué* in France. He informed them that as a committee they had no power to take legal proceedings as in England, and if they wanted to recover anything in the bankruptcy they must at once get somebody appointed who would stand in a legal position as the representative of the Company. That was one of the reasons why they had taken the step they had done for presenting a petition for winding up compulsorily. Another reason was that they had letters from different creditors which left no doubt in his mind or in that of the majority of the committee that if they had not presented the petition themselves some of the creditors would have done so, and the liquidation would have fallen into hands which he for one would have been very sorry to see. They therefore felt that the only course open to them was to present a petition for voluntary liquidation, getting a provisional liquidator appointed who would be in a position to carry on the affairs of the Company, and having done so they would have breathing time, so to speak, to look round and place before the shareholders the true state of matters, and take their opinion as to whether they should go on with the compulsory liquidation, or whether they should have a voluntary one. He need hardly say that if they went into a voluntary one an immense amount of expenditure was saved. Every step taken with regard to a compulsory liquidation was taken, so to speak, under an order of the Court, which could not be got under several guineas, whereas if they had a voluntary liquidation the liquidator had simply to act on his own responsibility, and whenever he was in any difficulty to go to the shareholders, and if they could not determine what to do he could fall back on the Court and get its orders. Under these circumstances he thought it would be best to pass the resolutions contained in the notice convening the meeting.

A brief and unimportant discussion ensued, in the course of which the advantages of the voluntary system of liquidation were duly set forth by Mr. L. A. Solomon and others.

The following resolutions were finally adopted, with but very few dissentients:—"That Messrs. Harcourt-Turner, Wm. D'Oyly, and Edward Ponsonby be and they are hereby appointed directors of the Company."—"That a sum of 80 guineas be given to the directors as a remuneration, it being understood that this amount should be divided among the committee as well as among the directors," and "that the Faure Electric Accumulator Company (Limited) be wound up voluntarily under the provisions of Section 129 Sub-section 2 of the Companies Act, 1862."

A vote of thanks to the chairman and the committee having been passed the proceedings terminated.

AN ELECTRICAL POCKET BOOK

OF RULES AND TABLES FOR THE USE OF ELECTRICIANS AND ENGINEERS.

By JOHN MUNRO, C.E., and A. JAMIESON, C.E., F.R.S.E., M.S.T.E.

GENERAL CONTENTS: Units of Measurement—Measures—Testing - Conductors—Dielectrics—Submarine Cables—Telegraphy—Electro-Chemistry and Metallurgy—Batteries—Dynamos and Motors—Electric Lighting—Miscellaneous.

London: Charles Griffin and Company, Exeter Street, Strand.

Digitized by Google

NOTES.

AN EXHIBITION AT BOSTON, U.S.—There is to be an Electrical Exhibition at Boston this winter.

THE KINETIC ENGINEERING COMPANY.—This company have removed to 37, Brooke-street, Holborn, E.C.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 20th inst. were £2,786.

CABLES REPAIRED.—The cable between Chorillos and Mollendo and that between Pernambuco and Ceara is now repaired.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 20th instant amounted to £3,516.

EARTHQUAKE IN INDIA.—News from India says that a sharp shock of earthquake was felt in Darjeeling and neighbourhood about 10:17 a.m. on May 18.

PROVISIONAL ORDERS.—Electric Lighting Provisional Order Bill, No. 3, passed through Committee, and was reported to the House of Lords on Tuesday.

FRENCH ACADEMY OF SCIENCES.—M. Jamin this week assumed the post of perpetual secretary to this academy, to which he was elected a few days since.

TELEGRAPH REVENUE.—The receipts from the Post Office Telegraphs from 1st April to 24th June were £355,000, compared with £350,000 for the same period of last year.

THE GAS ENGINE.—According to Prof. Dewar, a gas engine of 2 or 3 horse-power is more economical than a steam engine of the same power; but for higher powers this is not the case.

GILCHRIST ENGINEERING SCHOLARSHIP.—At University College on Wednesday, the Gilchrist Engineering Scholarship, £35 per annum for two years, was awarded to R. F. Hayward, of Harrow.

GALICIA.—Owing to heavy floods, telegraphic communication between Cracow and Lemberg and other towns in Galicia and Moravia was interrupted last week, and we believe still remains so.

ELECTRIC ASSOCIATION.—A general meeting of this company is to be held at Hatton-court, Threadneedle-street, E.C., on the 25th proximo, to receive the liquidator's account of the winding up.

EASTERN EXTENSION TELEGRAPH COMPANY.—The directors of this company have declared an interim dividend for the quarter ended March 31 last of 2s. 6d. per share, free of income-tax.

THE J. B. ROGERS COMPANY.—Creditors of this company are requested to send their claims, &c., to Mr. F. G. Painter, 2, Moorgate-street-buildings, E.C., the official liquidator, before the 14th proximo.

POSTAL TELEGRAPHS.—According to the Civil Service Commissioners' Report for 1883, just issued be it noted, there were 1,848 candidates for 160 vacancies among male and female telegraph learners.

ELECTRIC LIGHTING IN LEIPZIG.—The gas company at Leipzig intends, says a contemporary, to ask the Municipal Council of that town for a concession for lighting the streets and houses by electric light.

THE NEW ATLANTIC CABLE.—A message from Lloyd's states that the steamer "Faraday," from London for Halifax, passed the Lizard at 2:10 p.m. on Wednesday, to complete the laying of the new Atlantic cable.

SOUTH KENSINGTON MUTUAL ELECTRIC LIGHTING COMPANY.—Mr. Justice Kay has fixed 12 o'clock on Wednesday next, at the Royal Courts of Justice, for the appointment of an official liquidator of this company.

HYGIENIC AND ELECTRIC ASSOCIATION.—At a meeting of this association, held at 285, Lake-road, Landport, on the 7th inst., it was resolved to wind up voluntarily. Mr. H. R. Viggers has been appointed liquidator.

TELEPHONE WIRES IN CHICAGO.—There are 500 miles of wire in use in this city. The authorities are beginning to have them put underground. Sixty miles will be laid this year under the superintendence of Professor Barrett.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The coupons due on Monday next on the debentures of this company will be paid by Messrs. Barclay, Bevan and Co. The coupons must be left three clear days for examination.

ELECTRIC LIGHTING IN THEATRES.—There are 2,862 lamps in the Edison installation in the Teatro della Scala, at Milan, this being perhaps the largest installation of its kind in existence. It has been running since last winter without the slightest hitch.

THE FORTH CABLE.—On Tuesday telegraphic communication was all but stopped by the breakdown of the Forth telegraphic cable, supposed to have been caused by the anchor of some vessel having come in contact with it. Partial communication was restored at a late hour.

INTERNATIONAL PATENTS.—According to a statement recently made by Mr. Chamberlain, efforts will be made to complete the necessary formalities for enabling the terms of the International Convention for the Protection of Patents to take effect on July 7th.

"FREE COMPETITION!"—We are informed on very good authority that the United Telephone Company have bought up the London and Globe Telephone Company, an arrangement which we need hardly say will result in a practical monopoly over a very considerable telephone area.

ELECTRIC LIGHTING IN MALVERN.—The establishment of Messrs. H. and F. Davis, art screen manufacturers, Waterloo House, Malvern, is now lighted by Swan incandescent lamps. A Ferranti dynamo, excited by a small Siemens machine, supplies the current. Messrs. Davis are agents for the Hammond Company.

THE PARIS FIRE BRIGADE.—According to a recent report of the French Prefect of Police relating to the organisation of the Paris Fire Brigade, there are 190 stations in telegraphic communication with the chief offices and where the alarm of fire may be given, the telegraphic wires in use extending to a total length of 350 kilometres (about 220 miles).

QUICK WORK.—A somewhat remarkable example of the use of the telegraph was witnessed on Monday night in the House of Commons. While Mr. Gladstone was delivering his speech, says the *Standard*, many of the members were in possession of a summary of M. Ferry's statement delivered two hours before, and were able to compare it with Mr. Gladstone's.

WEATHER REPORTS AND THE HARVEST.—It appears that farmers who wish to have telegraphic weather reports from the Meteorological Office during harvest time can do so by paying a shilling for each telegram. If copies of the same telegram are

Digitized by Google

taken by other farmers in the same delivery district the cost of each additional copy will only be threepence.

SOCIETY OF ARTS.—The council of this society have awarded a silver medal to the authors of the following papers read during the last session:—Professor Fleeming Jenkin, F.R.S., for his paper on "Telpherage;" Mr. I. Probert, for his on "Primary Batteries for Electric Lighting;" Professor Silvanus P. Thompson for his on "Recent Progress in Dynamo-Electric Machinery."

ELECTRIC LIGHTING IN STUTTGART THEATRE.—The plant in this installation consists of 4 boilers and 2 engines capable of working up to 100 horse-power and making 130 revolutions per minute. The latter drive four Edison K dynamos, whilst an E dynamo is driven by a separate and smaller engine. The total number of lamps, 32, 16, and 10 candle-power, distributed throughout the theatre is about 880.

QUICKSILVER MINES.—According to Mr. J. B. Randol, of San Francisco, there were about thirty mines in California producing quicksilver in 1876. Many of these were only experiments. The locators were unable to make any money out of the business, and so suspended operations. Out of the twenty-seven mines that have produced quicksilver in the last eight years only five are known to be in operation now.

DONATIONS TO THE CITY AND GUILDS INSTITUTE.—The following additional donations to tne equipment fund of the Central Institution have been voted in response to the appeal of his Royal Highness the Prince of Wales:—The Goldsmiths' Company, £4,000 (subject to confirmation); the Salters' Company, £525; the Cordwainers, £250; and the Plasterers have increased their annual subscription from fifty guineas to £100.

UNITED TELEPHONE COMPANY.—The directors of this company have decided, subject to audit, and after making provision for depreciation, &c., to recommend at the forthcoming annual general meeting a dividend for the second half year ending April 30, 1884, at the rate of 5s. 6d. per fully paid share, part paid shares receiving in proportion, making, with the interim distribution in January, a total dividend for the twelvemonths ending April 30 last of 8 per cent. per annum.

A SHIP STRUCK BY LIGHTNING.—A despatch from Derry, dated 22nd inst., says:—"Captain M'Cann, master of the Derry barque 'Village Bell,' arrived in port this evening from Baltimore. He reports having eight sailors on board belonging to the Spanish ship 'Angeleta,' from New Orleans to Barcelona, which was struck by lightning and set on fire." The message states that the whole of the crew were rescued, and makes no mention of any casualty amongst them. The ship appears to have been burnt to the water's edge.

CASSELL AND CO.'S PUBLICATIONS. — *Cassell's Technical Educator* contains articles on "The Electric Telegraph," "Technical Drawing," "Applied Mechanics," &c. *Cassell's Family Magazine* for this month has an article on "Our Earthquake Experiences," which refers to the recent earthquake in Essex, besides the usual excellent miscellaneous articles and serial stories. "The Gatherer" columns of the same magazine contain notes on "A Watch Demagnetiser," "Electric Light Conductors," "A Cheap Lightning Rod," "New Applications of the Electric Light," &c.

MUIRHEAD'S DUPLEX SYSTEM.—A report of the case of Muirhead *v.* the Direct United States Cable Company, in which the plaintiff sued the defendants for arrears of royalty for the use of plaintiff's duplex system, will be found in another column. A fault was discovered in the cable some time since, which rendered duplex working impossible, though simplex working could be continued. The defendants therefore refused to pay the plaintiff's royalty. The whole question turned on the construction to be placed upon the words "operate satisfactorily" contained in an agreement between the parties. The judge gave judgment for the plaintiff, but stayed execution.

THE ROYAL ACADEMY.—The President and Council of the Royal Academy of Arts held their annual *conversazione* on Wednesday night in the galleries at Burlington House. Perhaps, says *The Times*, from a chivalrous regard on the part of the council for those artistically compounded complexions which Mr. Malcolm Morris has so severely criticised, the yellowish-red flare of gas was not replaced by the pure white glow of the incandescent electric light, so that since it was impossible under such conditions to look at the pictures with any pleasure, it follows, as of course, that the people who thronged the rooms were the chief attraction of the evening.

CABLE BETWEEN JAPAN AND THE KOREA.—The following notice to mariners has been issued by the Admiralty:—"A cable has been laid in Korea Strait from Kotomura (lat. 33° 32¾′ N., long. 129° 55½′ E.), north-west coast of Kiusiu, Japan, to Tsau-liang-hai (Fusan or Chosan Harbour), south-east coast of the Korea. The cable is landed at intermediate stations on Iki Sima and Tsu-sima. From Kotomura it is laid between Kagara Sima and Oögawa Sima to the eastern shore of Go no Ura (Gonolbra), Iki Sima; thence to Itsuhara Harbour, on the east coast of Tsu-sima; and finally from Komada (Komotamura), on the west coast of Tsu-sima, to the Japanese Station at Fusan. In the inner part of Fusan Harbour the cable is marked by buoys."

THE SUNDA STRAITS DISASTER.—Mr. R. D. M. Verbeck, a mining engineer in the service of the Netherlands Indian Government, who was commissioned in October last to inquire into the recent volcanic disturbances in the Sunda Straits, is of opinion that the volcanic character of Krakatau and the country in its neighbourhood arises from the fact that a cleft exists in the earth's surface at that point which admits of the admission of water into the interior of the earth. The water coming in contact with molten matter generates steam, which he thinks is the prime mover in most if not all volcanic eruptions. Mr. Verbeck estimates that a circle described from Krakatau with a radius of thirty degrees, or 2,080 miles, would pass through the farthest places where the tremendous reports which accompanied the eruptions were heard.

EARTHQUAKES IN ENGLAND.—In a recent paper read before the North of England Institute of Mining and Mechanical Engineers by Professor Lebour, the author dealt with the series of earthquakes which have been felt in Sunderland from December, 1883, to the present time. He thinks that falls of cavern roofs at moderate depths in the magnesian limestone, which is much fissured and hollowed out by the action of water, are sufficient to account for the shocks felt. Another paper by Mr. M. W. Brown endeavoured to show the connection between earth tremors and sudden outbursts of fire-damp in mines. He thinks that there are many cavities in the earth's crust filled with gas, which escapes when an earth tremor occurs through fissures opened by this means, and that if this happens in the neighbourhood of a mine the result is an outburst of gas into the latter.

THE TELEPHONE AND THE POST OFFICE.—In consequence of the attitude assumed by the Government towards the proprietors of telephones, says the *Daily Telegraph* of Saturday last, Mr. Jacob Bright intends, when the vote for Post Office

Digitized by Google

telegraphs comes before the House, to move: "That the telephone having become indispensable for purposes of public business the public interest requires that the telephone companies should, after paying a reasonable royalty to the Post Office Department, be absolutely free in the conduct of their business, it being understood that communication must be by conversation and not by messages in the place of the telegraph." From another note in this week's issue it will be seen that Mr. Fawcett has expressed his willingness to consider any suggestions that may be made by the telephone companies.

TELEPHONE COMPANIES.—In the House of Commons, on Tuesday, Mr. Fawcett, in reply to Mr. Slagg, said:—I am frequently asked by the various telephone companies to modify in different respects the existing terms on which they carry on business. I am therefore about to propose that the telephone companies should meet and endeavour to come to an agreement as to the modifications of those terms which in their opinion would meet the public requirements. Should they act upon this suggestion and communicate the result to me in writing, their proposals shall at once be carefully considered, with every desire to allow the greatest freedom possible to telephonic communication which is compatible with due protection of the interests of the revenue. In answer to Mr. Gray, the right hon. gentleman added that should he receive from the telephone companies such a communication as he referred to he would do his best to come to a decision upon it as soon as possible.

ELECTRIC LIGHTING OF THE HOUSE OF LORDS.—In the House of Lords, on Thursday, the 19th inst., Lord Greville asked whether any steps were about to be taken as to the lighting of the House by the electric light; also, having in view the great importance of obtaining the best and most economical results, whether Her Majesty's Government would ask the leading companies in Great Britain to tender for the same. Lord Sudeley: In reply to the noble lord, I am unable to say exactly when the House and the libraries will be lighted by the electric light, but the First Commissioner of Works has at present the lighting of both Houses under his consideration. As a considerable amount of money will have to be expended, the plans connected with it naturally require most careful looking into; and as a portion of the work has been carried out by one company, the First Commissioner is unable to say to what extent it will be possible to invite public competition, but he hopes he may be able to do so.

GAS AND ELECTRICITY IN FRANCE.—The eleventh annual Congress of the Société Technique de l'Industrie du Gaz was held at Paris on the 17th and 18th of June, under the presidency of M. Marché. Four medals were conferred on the authors of communications relating to gas and electricity, and amongst the recipients were M. Delahaye, for his paper on "L'Industrie de l'éclairage electrique en 1883," and M. Monnier for four papers on "Photometrical Standards," "The Napoli Photometer," "The 8 Horse-power Otto Motor," and the "Siemens Electrical Pyrometer." The expenses of maintaining M. Monnier's electrical laboratory are, says the *Révue Industrielle*, defrayed by certain gas companies. In the course of his presidential address, M. Marché paid a tribute to the late M. Dumas, and proposed that his name should be given to the photometric standard adopted by the International Conference of Electricians. "Gas engineers are," he said, "labouring to become electricians, they acquire from the latter whatever of the practical there is in their discoveries, and the result will be that gas will come out of the struggle more powerful than ever."

THE PLATINUM STANDARD.—In the course of a recent lecture at the Royal Institution, Professor Dewar made some remarks relative to the new photometrical standard recently adopted at Paris. He stated that as platinum grows hotter the relative proportions of red and green rays emitted by it vary, the following being the results obtained from some experimental researches of his own on the light radiation of the metal:—

Temperature. Deg. cent.	Luminous intensity. Red rays.	Green rays.
954	1·00	1·00
1045	3·27	3·64
1500	154·00	219·00
1775	507·00	809·00

He added that the object of the platinum standard is not, as erroneously supposed sometimes, that every man who indulges in photometrical experiments shall carry about a quantity of melted platinum with him, but that this more perfect standard shall be one with which the standard, but imperfect, candles and lamps at present used in photometric work may be compared. The French Carcel lamp, he added, is decidedly a more perfect instrument for measuring luminous intensity than the English standard candle. The last temperature given in the foregoing table, 1,775 centigrade, is close upon the melting point of platinum, and in measuring the intensity of light, mean white light is chosen, not individual rays.

EXHIBITION AT ANTWERP.—The committee for organising the electrical section of the proposed Universal Exhibition at Antwerp in 1885 has been definitely constituted. Amongst the members we notice the names of MM. Banneux, chief engineer of Belgian Telegraphs; De Cazenove, chief of the Technical Department of the Belgian Bell Telephone Company; Gérard, of Liege University; Jaspar, electrical engineer of Liege; Melsens, member of the Brussels Academy of Sciences; Mourlon, Nothomb, Rousseau, Somzée, Van Rysselberghe, and Wybauw, of Brussels, all well known names in connection with electrical science. The committee has been divided into four sections. The first section, presided over by M. Rousseau, will deal with the study and teaching of electrical science. Section 2, with M. Delarge presiding, will concern itself with the transmission of signals and words by means of electricity. The third section, of which M. Somzée is president, will concern itself with the production of electric currents and electric lighting; and the fourth section, presided over by M. Melsens, will deal with general mechanics, electric conductors, and the application of currents. It is proposed to light the principal portions of the exhibition by means of the electric light, and to provide for the telephonic transmission of music and theatrical performances from Brussels, Ghent, Liege, or perhaps Verviers, to the exhibition at Antwerp. The scheme also includes the trial of electric launches in the Scheldt, and the propulsion of tramcars in Antwerp by electrical means.

A NEW DYNAMO.—At a meeting of the Paris Academy of Sciences on the 9th inst. a note by MM. A. Damoiseau and G. Petitpont was read, in which the authors described a new dynamo. They propose to make such modifications in the armature as shall permit of a higher E.M.F. being obtained for a given length of wire traversed by the current. The suggested improvement can be applied to machines of the Pacinotti type, the Gramme, Hefner-Alteneck, and Siemens. The expansions of the inducing poles are suppressed, and these poles approached the one to the other in such a manner as only to influence one portion of the ring, a fourth or eighth part for instance. The current is collected at three points of

Digitized by Google

the collector, one practically at the centre of the part corresponding to the portion of the ring influenced, the other two on either side of each pole. The authors have constructed a model, of which the ring in the shape of a disc carries 3·2 kilograms of 1·2mm. wire, and the electro-magnets 18 kilograms of 1·6mm wire. The pole surfaces are only 56cq. for each pole, and influence the ring on both faces. The length of wire between the two brushes is only 45m. With the electro-magnets connected in pairs, a current of 11·7 amperes and an E.M.F. of 64·5 volts is obtained at the terminals at a speed of 690 revolutions. At 1,854 revolutions they get 207 volts with an open circuit, and at 1,900 revolutions 180 volts at the terminals and a current of 23·5 amperes, with a resistance of about 7·5 ohms. The electrical duty under these conditions is ·763, when the machine gives more than 200 watts per kilogram of wire, which is nearly double the work given by present machines.

Electricity in the Lecture Room.—A correspondent of the *Scientific American* writes to that journal as follows:—"Having occasion to illustrate in a lecture some of the phenomena of atmospheric electricity, I desired to obtain as long strokes as possible. With the apparatus at hand the longest stroke I could obtain in air was 4¼in. I tried iron filings sprinkled on varnished glass, paper, and wood, but the results were not satisfactory. After several experiments I hit upon the following exceedingly successful method: I fastened dry boards together to make a plane surface, 4ft. long and 3ft. wide. One side of this I varnished, and before it was dry pressed over its entire surface sheets of tin foil. After letting it stand over night to dry slightly, with a ruler I passed a sharp knife across the foil in lines about ⅛in. to ¼in. apart. Allowing it to dry a short time, I passed the knife across it right angles to the former lines, thus cutting the foil into squares, separated by very short distances—only the thickness of the knife edge. Connecting the poles of my coil to opposite ends of the board, a phenomenon of dazzling beauty was produced. Every time the circuit broke, from 6 to 20 streaks of lightning zigzagged from one end of the board to the other. These were exceedingly brilliant in the dark, when the circuit was broken only about 180 to 200 times a minute. Judging from the resistance of vacuum tubes placed in the circuit at the same time, I believe I can obtain strokes from 15ft. to 20ft. in length by this method, if the foil be placed in a narrow strip along a pole of that length. The drying mentioned above is necessary, as it is very slow under the foil, and the strips will be pulled out of their places in the second cutting."

Electric Lighting at Wimbledon.—The experiments conducted by Mr. Preece at Wimbledon have now been concluded. The results are briefly as follow, according to the *Daily News* of Saturday last:—Taking 10 candles as the average effective illumination given by five cubic feet of gas in a street lamp, the cost works out to ¼d. per lamp per hour for incandescent lighting. The most efficient mode of distributing light in a street appears to be to hang a 50 candle-power lamp about 20ft. above the centre of the road at every 100ft. For reflecting purposes a polished nickel-plated iron surface of a slightly convex form and Trotter's dioptric system gave the best results. Our contemporary gave some information as to the lighting of Mr. Preece's house which is interesting:—"The motive power is derived from a gas engine of two horse-power; and one of the chief features is a very low electromotive force, by which danger to person from shocks is entirely eliminated. The pressure is only 25 volts, which is imperceptible; so that the wires and machines can be freely handled. Another important feature is the use of Planté's secondary cells as a regulator to the gas engine. By this absolute steadiness of light is ensured. Thirdly, there have been introduced the employment of movable fixtures, so that the electric light becomes as portable as candles or oil lamps. The lamps used are little (Woodhouse and Rawson) 10-candle lamps of extreme brilliancy. The effects are quite fascinating. Mr. Preece has carried the system so far as to illuminate his little daughter's doll's house with four 'fairy' lamps, while Taylor-Smith's portable lamps enable him to examine his greenhouses or his garden at night as by day."

The Electro-Deposition of Iridium.—In the course of a recent paper before the Boston U.S. Society of Arts, Mr. John M. Batchelder says:—"While engaged in some details relative to the engraving and printing of the charts issued by the Coast Survey in 1857, it occurred to me that engraved copper plates might be improved by the electro-deposition of a metal harder than the copper upon the surface of the plate, the object being the protection of the surface from oxide, greater durability, ease of wiping, and a retouching of the lines. I could hardly hope that the process would be applicable to the very fine intaglio lines, but it was found that they were uninjured, the deposit taking place first upon the prominent edges or borders of the lines, and not in the cut. The metal selected for this purpose was iridium, which was procured from the United States Mint. The solution for the bath is prepared as follows: Iridium and osmium, which have been separated from other ores, are fused with about three times their weight of nitrate of potass for about one hour, at a bright red heat, and the contents of the crucible poured upon an iron plate. After cooling, the mass is broken into small pieces, which are then to be treated with nitric acid in a glass retort having a condenser, by which the osmium is separated in the form of osmic acid; the iridium remaining in the retort is to be treated with hydro-chloric acid after removing the nitrate of potass by crystallization, and we then have the chloride of iridium. The solution should contain about one-eighth of an ounce of iridium to a gallon of water, to which about one-quarter pound of sulphuric acid should be added. The plate, when immersed in solution, is connected with the battery in the usual manner. On its removal from the solution it is found coated with iridium in the metallic state, and closely resembling the common steel plates."

Spectra of Silicon Fluoride and Hydride.—In a recent number of *Wiedemann's Annalen*, Herr K. Wesendonck had an article on this subject, the following abstract of which appears in the *Jour. Chem. Soc.* for June:—"As the author observed in a bought Geissler tube containing silicon fluoride the spectrum of carbonic oxide, he examined the result with especial reference to the spectra of silicon compounds, and the cause of the presence of that of carbonic oxide. Silicon fluoride was prepared in the usual way in an apparatus made entirely of glass, and fitted with stopcocks; this was connected with a Geissler tube. The apparatus was first exhausted, then the acid allowed to come in contact with a mixture of pure glass and fluorspar, and the apparatus again frequently exhausted until gas present was in all probability pure. However, with all this care the spectrum of carbonic oxide was always visible, and mixed with that of silicon fluoride. At comparatively high pressures, when the discharge gave a continuous cylinder of light, there was observed a more or less continuous carbonic oxide spectrum with the characteristic eight blue bands of silicon tetrafluoride; with decrease of pressure, the spectrum varied precisely in the same manner as that of carbonic oxide, the eight blue bands became clearer,

Digitized by Google

and bands in the violet appeared. With the introduction of a Leyden jar in the circuit, Swan's carbon spectrum became visible. In another form of apparatus, in which the stopcocks and all lubricating material were avoided, the same phenomenon was observed. As the cause was proved not to be due to the action of the gas on the electrode, its probable explanation lies in the great avidity of silicon tetrafluoride for water. If by the contact of the gas with water a little oxygen were set free, the latter would possibly oxidise immediately any trace of carbon containing substances, such as dust, which might be present. The spectrum of a mixture of silicon hydride and hydrogen (formed by Wöhler's process) gave in narrow tubes only the spectra of carbonic oxide and hydrogen; in broad tubes under high pressure a number of lines which were observed in the silicon fluoride spectrum were visible, although the characteristic blue bands were absent; possibly the latter are peculiar to silicon fluoride."

City and Guilds Central Institute.—The Central Institution of the City and Guilds of London Institute was opened on Wednesday by H.R.H. the Prince of Wales, president of the institute. His Royal Highness was received by the Lord Chancellor, Sir Frederick Bramwell, and Sir Sydney Waterlow (the vice-presidents), Sir Philip Cunliffe Owen, Mr. Birkbeck, M.P.; Mr. B. Samuelson, M.P.; Professor Armstrong, Professor Ayrton, Professor Henrici, Professor Unwin, Mr. Philip Magnus, and others. In addressing the Prince the Lord Chancellor referred to the setting of the first column of the building by His Royal Highness on July 18, 1881. He stated that nothing was now wanting for its completion but some internal fittings, towards the provision of which the City and many of the London livery companies had in response to His Royal Highness's request contributed nearly £17,000. The total cost of the building when completed, would, he said, amount to nearly £100,000, and the council confidently trusted in receiving the balance still needed. In 1881 he had said that the number of candidates for the technological examinations was 1,563, as compared with 816 in the previous year; he was now able to state that the number examined in May of this year was 3,628, as compared with 2,322 in 1883. Referring to the work of the Royal Commission on Technical Instruction and their visit to the Continent, he said that they were able to report after three years' labour that no organisation like the City and Guilds Institute existed on the Continent, and that the opportunities afforded to workmen in this country to obtain by means of evening classes sound technical instruction compared favourably with those enjoyed by the same classes abroad. His Royal Highness in reply assured his hearers of the pleasure it gave him to be present, and his warm interest in the work of the Institute. Other speeches having been delivered, and thanks voted to the City and Livery companies, the officials and professors were presented to his Royal Highness, and the proceedings closed. We have received a copy of a pamphlet written by Professor Ayrton, entitled "A Short Notice of the City and Guilds of London Institute for the Advancement of Technical Education," written on the occasion of the opening of the Central Institution. It contains a short history of the foundation of the institute, its objects, some details of the instruction imparted and the methods of teaching employed, and other information of interest in this connection.

Electric Lighting on Ships.—The following extracts from a Government report made by Lieut. Seaton Schroeder, U.S.N., on the electric light on the U.S. Fish Commission steamer "Albatross," will be read with interest:—There are 136 Edison incandescent lamps on board; of that number, under ordinary circumstances, 40 to 45 are generally in operation the greater part of every evening, beginning at dark and ending at about 11 p.m. During the quarter ending March 31, 1883, 18 lamps have been disabled, as follows:—10 broken in handling, 4 burned out, 1 burned out by short circuiting of two branch wires, 1 gradually unscrewed from socket owing to vibration of hull, and fell on deck, breaking the glass and filament; 1 carbon filament broken by caulking the deck above, 1 carbon filament broken while experimenting. The invoice price of each lamp being 1 dol., the additional cost of illumination on account of breakage of lamps has been 18.00 dols. over and above first cost of plant. During the quarter the dynamo machine has run 540 hours. Of the 136 lamps in position 34 have been in operation the whole time, or 540 hours each = 18,360 hours in all; of the remainder, the hours of incandescence have been as follows:—

2—440 hours each	....	=	880	hours.
4—410 " "	....	=	1,640	"
22—340 " "	....	=	7,480	"
8—100 " "	....	=	800	"
20— 50 " "	....	=	1,000	"
18— 10 " "	....	=	180	"
		=	11,980	
34—540 " "	....	=	18,360	"
Total	....	=	30,340	"

The running expense in lamps has therefore been $\frac{18 \text{ dols.}}{30,340}$ = 59 one-thousandths of a cent per lamp in operation per hour. For illuminating the entire vessel the running expense in lamps has been $\frac{18 \text{ dols.}}{540} = 3\frac{1}{3}$c. per hour. The life of the lamps that have burned out has been as follows:—No. 49 (8 candle-power), 92 hours; No. 90 (8 candle-power), 369 hours; No. 68 (16 candle-power), 195 hours; No. 41 (8 candle-power), 99 hours. A mean of these would obviously be a very unfair showing of the average life of the Edison lamp. The imperfect ones give way first, and a correct average, of course, can only be had by waiting to consider the best as well as the poorest. It is only fair also to add that the breakage by accident has been greater than will probably continue to be the case, the crew being extremely raw, green, and unthinking. In handling the lamps—frequently without authority—they have apparently used more force, as a rule, and less dexterity than the occasion required, simple as their manipulation is. Familiarity with the light will doubtless decrease this source of expense. Furthermore, the lamp that was disabled by caulking over head was purposely left in place to test its safety under those conditions, it being attached to the deck that was being caulked. The burning of one by short circuiting occurred before the installation of the system was completed, and resulted from the loose ends of two branch wires coming in contact. The destruction of a third occurred during, and was apparently caused by, some experiments, which proved an abnormal condition for an incandescent system of illumination. As shown above, only four of the eighteen have burned out, which would reduce the legitimate running expense to $\frac{4 \text{ dols.}}{30,340} = 13$ one thousandths of a cent. per lamp in operation per hour, or $\frac{4 \text{ dols.}}{570} = 74$ one-hundredths of a cent. per hour, for lighting the vessel. Some of the globes have begun to be discoloured by the wasting of the filaments—Crooke's effect—but not sufficiently to affect sensibly the amount of light given out. Apart from questions of economy, the light commends itself strongly for use on shipboard.

ELECTRO-CHEMISTRY.—Inorganic.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 126.)

Separation of Aluminium.—Al. Electro-chemical equivalent $= \frac{27 \cdot 5}{3} = 9 \cdot 16$. A triad cation. Magnesium by simple immersion in solutions of aluminium salts produces aluminic hydrate (S. Kern, *Chem. News*, Vol. XXXIII., p. 236). Magnesium does not deposit aluminium as metal from its solutions (Roussin, *Chem. News*, Vol. XIV., p. 27). An amalgam of aluminium is formed by contact of the metal with sodium amalgam and water (Watts's "Dictionary of Chemistry," Vol. III., p. 886).

Various persons have stated that aluminium cannot be deposited by the aid of a separate electric current. "The electrolytic reduction of aluminium may be performed either in the wet or in the dry way. The reduction from the fused chloride of aluminium and sodium was first effected by Bunsen in 1854. The salt is introduced in a fused state into a red hot porcelain crucible, divided into two parts by a porous earthenware diaphragm, and the extremities of the poles of a Bunsen battery of ten elements are introduced into the two halves of the fused mass. The metal is then reduced at the cathode, and if the temperature is sufficiently high the metal is melted into globules" (Watts's "Dictionary of Chemistry," Vol. I., p. 152).

M. H. St. Claire Deville says:—"It appeared to me impossible to obtain aluminium by the battery in aqueous liquids. I should believe this to be an impossibility if the brilliant experiments of M. Bunsen on the production of barium did not shake my conviction. Still, I may say that all processes of this description which have recently been published for the preparation of aluminium have failed to give me good results. It is of the double chloride of aluminium and sodium, of which I have already spoken, that this decomposition is effected. The bath is composed of two parts by weight of chloride of aluminium, with the addition of one part of dry and pulverised common salt; the whole is mixed in a porcelain crucible, and heated. The combination is effected with disengagement of heat, and a liquid is obtained which is very fluid at 392°F., and fixes at that temperature. It is introduced into a vessel of glazed porcelain, which is to be kept at a temperature of about 392F. The cathode is a plate of platinum on which the aluminium (mixed with common salt) is deposited in the form of a greyish crust. The anode is formed of a cylinder of charcoal, placed in a perfectly dry porous vessel, containing melted chloride of aluminium and sodium. (The densest charcoal rapidly disintegrates in the bath, and becomes pulverulent, hence the necessity of the porous vessel.) The chlorine is thus removed with a little chloride of aluminium proceeding from the decomposition of the double salt. This chloride would volatilise and be entirely lost if some common salt were not in the porous vessel. The double chloride becomes fixed, and the vapours cease. A small number of voltaic elements (two are all that are absolutely necessary) will suffice for the decomposition of the double chloride, which presents but little resistance to the electricity. The platinum plate is removed when it is sufficiently charged with the metallic deposit. It is suffered to cool, the saline mass is rapidly broken off, and the plate replaced" (*The Chemist*, New Series, No. XIII., October, 1854, p. 12). By the electrolysis of fused sodic aluminic chloride the aluminium deposited contains silicium derived from the charcoal electrodes (Deville, Watts's "Dictionary of Chemistry," Vol. I., p. 152, and Vol. V., p. 267).

According to A. Bertrand, by means of a separate current aluminium is deposited on a copper plate in granules from aluminium ammonium chloride, whilst chlorine is evolved at the anode (*Jour. Chem. Soc.*, 1877, Part I., p. 161. *Chem. News*, Vol. XXXIV., p. 227). M. Corbelli deposits the metal by electrolysing a mixture of rock alum, or sulphate of aluminium, and the chlorides of calcium or of sodium, the anode being formed of iron wire coated with an insulating material, and dipping into mercury placed at the bottom of the solution, and the cathode of zinc immersed in the solution. Aluminium is then deposited upon the zinc, and the chlorine which is eliminated at the anode unites with the mercury and forms calomel (Watts's "Dictionary of Chemistry," Vol. I., p. 152).

Thomas and Tilley state that they deposit aluminium from a solution composed of freshly precipitated alumina dissolved in boiling water containing cyanide of potassium; also from a solution of calcined alum in aqueous cyanide of potassium, and from several other liquids. They also state that they have deposited alloys of aluminium and silver, aluminium, silver, and copper; aluminium and tin; aluminium, silver, and tin; aluminium and copper; aluminium and nickel; aluminium and iron, &c. J. B. Thompson says that he has for more than two years been depositing aluminium on iron, steel, and other metals, at a temperature of about 500 F., and also depositing aluminium bronze of various tints from the palest yellow to the richest gold colour (*Chem. News*, Vol. XXIV., p. 194). Jeancon deposits the metal from an aqueous solution of a double salt of aluminium and potassium of specific gravity 1·161, at a temperature of 140° F., by means of a current from three Bunsen's cells (*Telegraphic Journal*, Vol. I., p. 308). T. Ball also deposits it from the double chloride of aluminium and potassium (*Chem. News*, Vol. V., p. 153).

I electrolysed a strong solution of aqueous fluoride of aluminium, containing free hydrofluoric acid, with large sheet platinum electrodes and a strong current. Gas was evolved freely from the anode, and the liquid became heated.

Aluminium used as an anode in dilute sulphuric acid largely stops the current, probably by becoming coated with a layer of insulating oxide; but if employed only as a cathode it is not thus affected (*Chem. News*, Vol. XXXI., p. 99; *Telegraphic Journal*, Vol. III., p. 59).

It may be superficially coated with mercury by being made the cathode in contact with mercury in acidulated water (Cailletet, *Comptes Rendus*, XLIV., p. 1,250; also Watts's "Dictionary of Chemistry," Vol. VII., p. 54).

Aluminium, like magnesium, has great power in reducing metallic solutions and depositing their metals by simple immersion process; it reduces those of silver, mercury, copper, lead, thallium, and zinc (*see* A. Cossa, Watts's "Dictionary of Chemistry," Vol. VII., p. 54).

For the use of electrolysis in the metallurgy of aluminium, *see* F. Fischer, *Jour. Chem. Soc.*, Vol. XLIV., 1883, p. 399. For the electrolytic analysis of compounds of aluminium, *see* V. Francken, *Chem. News*, Vol. XLVI., p. 106; also *Jour. Chem. Soc.*, Vol. XLII., 1882, p. 132; and A. Claessen, *ibid*, p. 896.

Separation of Glucinum.—Gl. Atomic weight = 9·3. A cation. Nilson and Petterson were unable to separate this metal by the separate current method (*Chem. News*, Vol. XXXVII., p. 195). Becquerel deposited the pure metal from a concentrated solution of its chloride by means of a current from twenty voltaic cells. It was in the form of brilliant, steel grey crystalline laminæ (Gmelin, "Handbook of Chemistry," Vol. III., p. 293).

For the electrolytic analysis of its compounds, *see* A. Claessen, *Jour. Chem. Soc.*, Vol. XLII., 1882, p. 896.

Separation of Calcium.—Ca. Atomic weight = 40. According to Klauer, calcium amalgam may be formed either by simple immersion of sodium amalgam in solutions of calcium salts, or by passing a strong electric current from those liquids into mercury. Herschel observed that during the electrolysis of a solution of calcic chloride by means of a separate current, the cathode evolved gas and became coated with caustic lime.

This metal was first separated by an electric current during the year 1808 by Sir H. Davy, who obtained it as an amalgam by employing a cathode of mercury. Fremy subsequently electrolysed pure calcic fluoride in a fused state in a platinum crucible. Brisk effervescence occurred in the mass, a gas was set free at the anode, metallic calcium was deposited upon the cathode and became converted into lime by the oxygen of the air. It was difficult to make the observations, and the crucible was soon alloyed and perforated by the action (*The Chemist*, New Series, Vol. II., p. 548).

Digitized by Google

Matthiessen electrolysed a fused mixture of two molecules of calcic and one of strontic chloride with a small amount of sal-ammoniac in a porcelain crucible. The anode was of gas carbon, and the cathode was formed by winding a thin iron wire round a thicker one and dipping its end only just into the liquid. The calcium was set free as metallic globules upon the thin wire. He states that the metal deposited upon the cathode by a separate current in a fused mixture of chloride of calcium and the chlorides of potassium or sodium is not calcium (Watts's "Dictionary of Chemistry," Vol. I., p. 715).

Bunsen deposited calcium in a similar manner to that employed for manganese (*see* paragraph on "Separation of Manganese"), except that he used a greater density of current. He acidulated a concentrated and boiling hot solution of the chloride with hydrochloric acid, poured the boiling liquid into the porous cell, and employed as a cathode an amalgamated platinum wire. The calcium was deposited as a grey layer upon the amalgamated surface. The process is difficult, because the calcium quickly oxidizes to a layer of lime, which covers the cathode and stops the current. The deposit must be frequently removed, and the wire freshly amalgamated each time before re-immersion; and even then but a small amount of the metal is obtained (*The Chemist*, New Series, Vol. I., Part 2, p. 686, August, 1854).

INCANDESCENT LIGHTING.

BY T. H. SEYMOUR HAWKER.

As the electric light is placed more and more fully on a commercial basis as an illuminant it becomes very necessary to formulate and conventionalise a systematic method of installing the necessary conductors and apparatus.

The present incandescent lamps are undoubtedly as yet very far from perfection, being in fact merely in a transitionary stage, but we can safely leave their development to the usual process of evolution, stimulated by competition.

The great adaptability of electrical generators to any required conditions of supply enables us to foresee that the mere question of the best method of installing will remain practically the same, no matter what improvements may take place in the lamps or the energy-source.

We have indeed already seen in the many systems which have come before the public nearly every possible arrangement of lamps in combinations of series and parallel connections to suit machines of different types.

These varied permutations must be regarded more in the light of concessions to the weaknesses of their respective systems than as indicating difference of opinion as to which method of installation possesses the greatest advantages.

It is only to be expected, for instance, that the advocates of a machine best suited to high tension work, failing to obtain single lamps of suitable resistance, should unwillingly consent to adopt an arrangement involving series coupling.

The disadvantages attending any system of series connections are obvious.

All the lamps in a series are mutually dependent, and in the absence of any compact form of high resistance shunt one cannot be switched off without extinguishing the others.

The danger of accidental extinction can be, to a certain extent, obviated by duplicating the lamps, and using an automatic switch in the holder, which cuts in a new lamp on the breaking of either of those in a series.

This has many objections other than mere expense and unsightliness, and is, in fact, quite inadmissible in any system claiming to be adequate to the exigencies of public supply.

There is, moreover, no reason other than the present undeveloped condition of electrical industries (which, by the way, needs only the stimulus of greater national commercial prosperity) why any machine with a *reasonably* high tension should not be used with a logical and coherent system of lamps of suitable resistance connected *all in parallel.*

The complete independence of all lamps in a parallel circuit, together with the ease with which a circuit can be systematically wired and distributed to give very low resistance with any desired arrangement of lamps, makes this system ideally perfect. It is assuredly the parallel circuit which will be prevalent in the future, and I will therefore principally consider the principles involved in the practice of incandescent lighting on this system.

The chief desiderata to be kept in view are good circuit efficiency, equality of E.M.F. at the terminals of all the lamps, economy of copper so far as is consistent with high efficiency, and general simplicity of details, combined with solid workmanship.

The first mentioned electrical attributes depend principally on the amount of copper which economical considerations can afford for the cabling, and the judicious planning of the circuit so as to subdivide the resistance in as many parallels as possible. By looping or joining *both* ends of a pair of branches to the mains, its resistance is halved, and current carrying capacity doubled. In house lighting this device can be very often used with advantage, especially when a large number of lamps are run in a single pair of parallels, as the distribution of E.M.F. is rendered very much more equable.

The general idea of any parallel circuit is that of two metallic extensions of the machine terminals, with ramifications extending in those directions which they would supply the greatest number of lamps, which are simply connected by each terminal to one of the polar extensions.

The conception of this is very similar to the physiological theory of blood circulation. The dynamo corresponds to the heart, and the positive polar extensions to the arteries. The lamps are the nerves supplied by the flow, and the negative polar extension the circuit completing veins.

When this idea is once grasped, the planning of a circuit depends almost solely on the architectural exigencies of the installation, and only very general rules can be laid down for guidance.

Of the greatest importance, especially when the commercial value of a lighting system depends on the economy of power, is the *efficiency* of the circuit. This is the ratio of the energy utilised in the circuit to the total energy supplied by the generator, and is in practice equivalent to *the ratio of the aggregate lamp resistance to the total circuit resistance*, including the generator.

In parallel connection the greater the number of lamps the less their resistance and the larger the current. With a sensible resistance of leads the increase of current will be rather less than directly as the increase of number of lamps, and the energy expenditure on a circuit of constant resistance being as the square of the current will vary nearly as the square of the number of lamps. If, therefore, we wish to have an equal efficiency with a doubled number of lamps we must employ leads equivalent to nearly four times the sectional area.

It should be remembered that each microhm of resistance between the generator and the lamps involves a loss of E.M.F., which increases directly with the number of lamps supplied thereby. Moreover, the generator itself must have an extremely low internal resistance, or the circuit efficiency will be much decreased and the energy wasted thereon will in addition injuriously heat the machine.

When using large currents, in fact, resistance must *everywhere* be minimised, as it in all cases means waste of energy, and by heating the conductors still further increases their resistance, possibly raising them to a temperature which, if permitted, might endanger not only the circuit but any inflammable materials in proximity.

To impress these principles more deeply let us take a practical example. Let us suppose that a building is lighted with 300 incandescence lamps of 20 candle-power, and working with a current of ·63 ampere at 100 volts. The resistance *hot* per lamp will be about 160 ohms, making an aggregate resistance in parallel of ·53 ohm. In order to have a circuit efficiency of 90 per cent., which is the least usually admissible, the total resistance of generator and mains must not be greater than ·06 ohm therefor.

Digitized by Google

The internal resistance of a generator of the Ferranti type will be about ·02 ohm, and as this factor cannot be further reduced without involving the construction of a special machine, it becomes necessary to select the conductors, and so plan the circuit that the remaining ·04 ohm may not be exceeded.

It is well to notice here that any resistance added in series to each of the individual lamps would have but little effect on the economy of energy. We can therefore use very small leads to the lamps themselves, so long as a safe limit of temperature is observed, but must keep the mains or those branches leading to groups of lights of ample size.

I have talked of the effects of *current* on resistance, my reason for doing so being that the heating effect is proportioned to the square of the current. Current, however, necessitates expenditure of E.M.F., and it will now be more convenient to consider resistance as expending E.M.F.

In order that all the lamps in a circuit shall burn at equal brilliancy, it is necessary to have either a constant E.M.F. at their terminals, or to grade the resistances of the lamps so that those which, by reason of the resistance of the leads between them and the generator, have a reduced E.M.F. shall make up for the deficiency by carrying an increased current.

It need hardly be said that on any very extended scale the former is the only practicable system, and we therefore see that care must be taken so to place the circuit as to attain uniform conditions at the lamps.

As an illustration let us consider the case of a long row of 100 lamps in simple parallel between the same pair of mains, which, in order to exaggerate the fault, we will take to be composed of single No. 12 B. G. wires. These will of course get very hot, but we will neglect this. Let us suppose the first lamp is 100 feet from the generator, which gives at its terminals a difference of potential equivalent to 61·5 volts. The resistance to the first lamp would only be ·096 ohm, but this will absorb the odd 11·5 volts. If the lamps were of such a resistance as to burn at full candle-power with the current due to 50 volts, the first lamp would then burn well, but the resistance as well as the current will fall off towards the end of the row, till the last lamp will have a very insufficient current. If the lamps be in groups of 10, and the common interval between the groups be 10 yards, the E.M.F. at each succeeding group will be less by the amount of the product of the intermediate resistance into the remaining current. We therefore get the following E.M.F. at the successive groups :—

No.	1	2	3	4	5	6	7	8	9	10
E.M.F.	50	43	39·2	35	32	29·5	27·3	25·3	23·7	22
Current per lamp	1·2	1·19	·94	·85	·775	·71	·659	·61	·57	·537

There are several ways of rectifying this inequality, which seems primarily dependent on the nature of the conductors and their arrangement, but, however, is greatly attributable to the lamps themselves using too much current and too little E.M.F., that is to say, being of too low resistance.

As we increase the E.M.F. in use, any slight variation of value due to lead resistance bears a less ratio to the whole than while driving a similar current previously. The effect on the lamps is therefore much less, other conditions equal; but as the high E.M.F. lamps require less current we have also a saving in the energy expenditure necessitated to drive a current through resistance. We may expect, therefore, to get much better results under the conditions previously stated with 100-volt lamps, which take only ·63 ampere each. The leads from generator to lamps only absorb six volts, and we can thus work with a margin of only 106 volts at the machine, which will give at the respective groups the following values :—

No.	1	2	3	4	5	6	7	8	9	10
E.M.F.	100	96·5	93·3	90	87·4	84·7	82	80	77·5	75·3
Current per lamp	·63	·61	·587	·567	·548	·53	·517	·5	·486	·475

We can decrease the defect indefinitely, therefore, by simply increasing the resistance of the lamps.

High resistances, however, at present mean very thin and weak filaments, although in the recent Bernstein and Cruto lamps there is an attempt to improve this, and we are therefore constrained to rely on a manipulation of the conductors to attain equality by reducing the resistance.

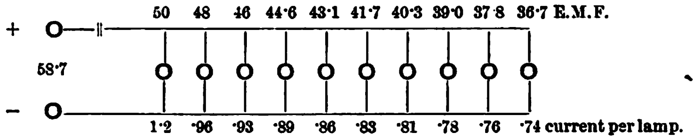
This can of course be done by increasing their weight, but a great deal can be done by subdividing the resistances so as to throw them into multiple arc.

This operation also includes the so called "looping" of circuits, which simply means the joining of a row of lamps to the mains by opposite ends of their leads.

To illustrate this, Fig. 1 gives a plan of the leads for 10 lamps in simple parallel. Fig. 2 shows the same lamps and leads subdivided, and Fig. 3 with the ends looped. The latter can be varied by what may be termed "double looping," in which both ends of each of the lamp leads are carried to the mains, as shown in Fig. 4.

It will be advantageous to analyse these typical elementary circuits, and to compare as a "figure of merit" the ratio borne by the minimum to the maximum E.M.F.'s in the several cases.

Fig. 1.



Single Parallel.

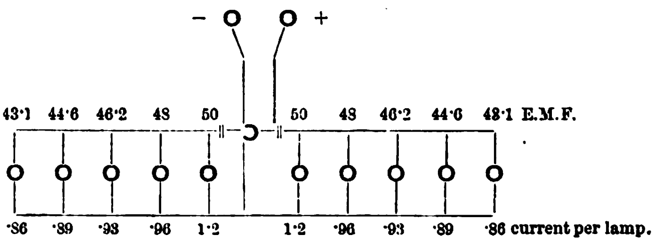
We will take the intermediate resistances for the sake of simplicity as equal, and equal to unity, and the current per lamp as unity also with an E.M.F. of 50 volts ideal. The resistance between the generator and lamps will be assumed at one ohm in each case.

It must be borne in mind, however, that these examples are merely exaggerations of the defects actually met with in practice.

To drive the 10 amperes through the 1 ohm leads will use up 10 volts ; so to get 50 volts at the lamps we must have 60 volts at the generator. The E.M.F. will then be distributed as shown in the diagram.

To give a general formula, let c = necessary current per lamp, r = resistance per lamp, a, b, c, d, e, &c. = the resistance of leads from lamp to lamp. E = E.M.F. of first lamp, n = number of lamps, η = E.M.F. of lamps, and ρ = resistance of leads from generator to first lamps.

Fig. 2.



Divided Parallel.

Then the current will be

$$C = E \cdot \Sigma\left(\frac{1}{r} + \frac{1}{r+2a} + \frac{1}{r+2(a+b)} + \frac{1}{r+2(a+b+c)} \cdot \cdot \cdot \cdot \right)$$

The E.M.F. at any lamp separated from the 50-volt point by a resistance $\beta = a+b+c$ . . . . *in both leads* will be $\eta = E - \left(\frac{E}{r+2\beta} \cdot 2\beta\right)$, and the E.M.F. which the generator must supply $= \epsilon = c\,\rho + E$.

The idea underlying these formulæ is capable of great extension and very general application to calculations of fall of potentials and currents.

Suppose a number of lamps be so arranged along a pair of conductors of resistance $\beta = a+b+c$, &c., so that the resistance to the first lamp being 0, that to the second will be a, the third $a+b$, the fourth $a+b+c$, and so on. Then the current for each lamp will have to pass through these respective

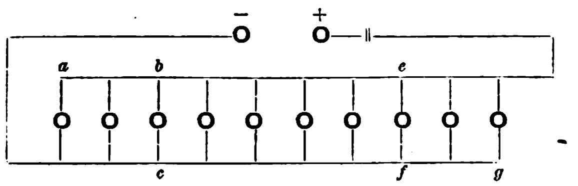
Digitized by Google

resistances, which will absorb proportionate E.M.F.'s. *The E.M.F. at any lamp is then the E.M.F. at the first lamp, minus the product of the leads resistance into the quotient of the E.M.F. by the total resistance of the circuit through and including the lamp.* We must imagine the total current to be divided into n parts, each equal to $\frac{E}{\Sigma(a+b+c \ldots \&c.)+r}$, and traversing different lengths of conductor to the respective lamps involving a loss of E.M.F. $= c\,(a+b+c.\,\&c.)$.

The simple parallel connection is plainly shown, therefore, to be unsuited to long rows of lamps, and renders a large section of conductor essential if uniformity of illumination is required without graling the lamps.

This uniformity, it should be remembered, is not merely a matter of abstract good appearances, but is vitally connected with the economy of working. If the E.M.F. in a circuit be very unevenly distributed, it will be generally necessary to

Fig. 3.



Single Loop.

burn some of the lamps at too high a candle-power, in order that those further off may give a decent light, and the excess of current simply melts away the lamps affected, shortening their "lives" alarmingly.

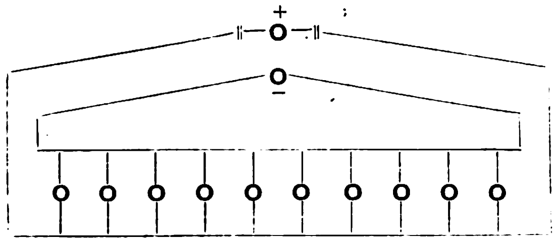
The same sizes of conductor can, however, be arranged for a much better effect, and in a way which is generally more convenient in practice.

In the circuit shown at Fig. 2 the mains are connected to the middle of the row of lamps, and the resistances of the leads are thrown into parallel arc as well as the lamps. The total current, however, still passes through the mains, and the absorption of E.M.F. therein remains as before.

Of course in practice this part of the circuit would be made of large section, so as to reduce the loss.

The range of variation of E.M.F. at the lamps is much less than in the preceding example, and the distribution generally much more convenient.

Fig. 4.



Double Loop.

By placing safety fuses at the points marked ||, this arrangement is also safer than the last, as only half the lights will go out in the event of a short circuit in one of the branches; but more of fuses anon.

The advantages accruing from thus subdividing the leads are so great that it should be a maxim in circuit planning to run "short parallels and many of them."

It is often possible, with a little ingenuity, to attain in this manner an equipotential and low resistance circuit without any further expenditure of copper on the conductors than would be necessary with long parallels and bad E.M.F. distribution. In any case, however, the equality and homogeneiety, if I may use the term, of the lighting should be before all other considerations, and it is therefore better to spend a few additional pounds in doing the cabling well.

It will be obvious that the previous formula can be applied to the calculation of current and E.M.F. at any lamp in this case also, if we take either of the two middle lamps as our starting point, and work outwards,

The single-looped current shown in Fig. 3 is not generally so easy of application as the former, but it has many advantages. We have here the mains connected one to each end of the row of lamps, and there is a tendency to equalise the E.M.F. by the compensation of the resistances of the leads—one increasing as the other diminishes.

The current supplying any lamp has to traverse a length of positive lead *to* the lamp and negative from the lamp, which have a constant sum when added together. Thus, if the mains be equal, the current for $b\ c$ traverses the length $a\ b+c\ g$, which is equal to the distance $a\ e$, $f\ g$, traversed by the current for the lamp $e\,f$, and so on.

The circuit is therefore perfectly equipotential, but it has the disadvantage that the current has to traverse a resistance equal to that to the farthest lamp of the row in every case. A deal of E.M.F., and consequently energy, is therefore lost, if the row be long.

If γ be the resistance of the lead to one end of the row, δ to that of the other, and ϕ the resistance of one of the leads running from first to last lamp, then if a current of c amperes is needed per lamp the generator must have an E.M.F. of $E=c\,(\phi+r+\delta+\gamma)$, and the total current simply $=nc$; while an uniform E.M.F. $= E-c\,(\gamma+\delta+\phi)$ is maintained at all the lamps.

In order to reduce the wastefulness of the leads in this method the system of "double-looping," shown in Fig. 4, may sometimes be employed with advantage when the circumstances connected with architectural design and distribution of lights will permit.

The writer has used the method advantageously in wiring the lights round the front of the balconies and circles of theatres where the ends of the parallel of lamps are not far apart. When, however, this is not the case the extra expense of mains may render its adoption unadvisable.

The leads are here duplicated and their resistance halved, but by so doing we have a falling off of E.M.F. towards the centre.

(To be continued.)

CORRESPONDENCE.

THE NATURE OF ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your last issue (p. 131) Professor Tait says:—"We now *know* that electricity is not a substance," and the statement is emphasized by the italics here reproduced. I am at a loss to imagine whom the "we" can refer to, for I am not aware that any discovery has been made to alter the aspect of the question as to the nature of electricity since Clerk-Maxwell observed that "we do not know whether positive electricity, or negative, or both, should be called a substance or the absence of a substance." It is well known that Faraday declared his inability to offer any opinion on the question. In regard to what used to be termed "the three imponderable elements," it may safely be stated that neither heat nor light is a substance or mode of matter. I grant that we *know* this. But, in regard to electricity, there are many scientific considerations which point to the possibility of its being a kind of matter, imponderable—though perhaps the cause of gravitation—and certainly *sui generis*, but as undestructible and inconvertible as common matter. I have gone further than this conclusion, and have ventured to maintain that electricity is most probably of a material nature. I use the term *electricity* in its original signification of electrical *quantity*, or that which, when a charged conductor is brought into contact with a similar uncharged conductor (the two conductors being under similar conditions), becomes equally divided between the two conductors, without being either diminished or increased. This value (Q)—electricity or electrical quantity—is measured by

Digitized by Google

current into time ($C\theta$), or by the ratio of potential difference to electrostatic resistance $\left(\frac{E}{R^i}\right)$. It is not *force* (pressure or pull), because we *know* that electrical force varies as Q^2 or E^2* (for a given surface), and that this value (as well as potential difference and the resistance in the electrostatic circuit) becomes halved when the above-mentioned conductors are brought into contact. Nor is it *energy*, for we *know* that electrical energy varies as Q E, and that this value also becomes halved—the remaining half becoming converted into *heat*—when the conductors are brought into contact, or connected by a conductor which may be supposed to have no charging capacity.

In electrical phenomena force and energy are continually varying, undergoing transformations and conversions. Electricity remains electricity; a coulomb of electricity cannot be converted into anything else, cannot be transformed into any mode of energy. It is as unalterable as a grain mass of hydrogen or aqueous vapour. The variations in the energy of which they are the vehicle cause the electricity, the gas, and the vapour to produce very different effects at different times; but electricity can no more be converted into heat than can a rifle bullet when its motion is arrested. But if electricity be neither force nor energy, and if it be absolutely inconvertible, is it not most probably a kind of matter analogues to which may hereafter be discovered?—Yours, &c.,

DESMOND G. FITZGERALD.

* $\text{Force} = \frac{Q^2}{S} = \frac{E^2}{R^2 S} = \frac{E^2 S}{l^2}$, S being surface and l reduced length of dielectric.

$\text{Energy} = Q\ E = \frac{E^2}{R^i} = \frac{E_i S}{l}$

THE COST OF ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I quite agree with the expression of opinion contained in Mr. Martin's letter in your last issue to the effect that the enormous price of the plant necessary for an installation of electric light is prohibitory to its introduction to mills and factories, where its advantages would tend so much to the comfort and heath of the *employés*. So long as interest and a moderate percentage for depreciation and repairs on plant amount to nearly as much as the price of gas per annum, so long will it be found extremely difficult to induce people to adopt this method of illumination.

Like your correspondent, I have prepared many estimates for electric light installations during the past couple of years, and have been usually met with the objection that the first cost was too great. Why cannot manufacturers offer dynamos at a reasonable price, leaving sufficient margin for profit? and especially why cannot incandescent lamps be sold at a more reduced price than five shillings? Surely the manufacturers of electric light apparatus are standing in their own light by continuing to demand fancy prices. With reasonable charges there would be a larger business, and consequently increased profits, to those engaged in the supply of electrical appliances.—Yours, &c.,

J. ANGELO FAHIE, M.S.T.E. and E.

10, Leinster-street, Dublin,
21st June, 1884.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent, Mr. Martin, has contributed some very interesting figures to prove that the mere interest and depreciation charges on an electric lighting plant of 520 incandescent lamps will equal the total cost of the gas lighting for a public works using 500 gas jets.

Mr. Martin has, however, omitted to debit the gas lighting with anything but the cost of the gas itself. In all fairness he should have added to it the interest and depreciation of the meter, pipes, and gas fittings fixed throughout the buildings. He should have also pointed out that his estimate for electric lighting plant provides for a light collectively equal to 10,200 candles, whereas the gas plant, on the supposition that one burner equals 12 candles, would collectively equal 6,000 candles. But, after these corrections have been made, the fact still remains that in this case the heavy interest and depreciation charges would so out-weigh the advantages afforded by the electric light that it is extremely unlikely that it will be largely used by Dundee manufacturers.

Your correspondent appears to think that the remedy lies in the cheapening of the electrical apparatus, but I think that your correspondent's figures merely prove that Dundee mill owners use their artificial light for such a small number of hours per annum; namely, taking 500 gas jets, costing £100 per annum, using 5ft. burners, and gas at 2s. 6d. per thousand, equal to using 322 hours only, the conditions are as unfavourable as possible for providing detached installations such as the proposed one.

If such short hours of use of artificial light is the rule in Dundee, it would be interesting to know whether it does not in some degree affect the price of gas itself, as the interest and depreciation charges incident to the manufacture and distribution of gas are annual charges, and having to be divided over a similar number of hours must be proportionately heavy.

The same rule applies to the electric light to a still greater degree, on account of the want of storage. Fortunately, in many towns artificial light is used in workshops and manufactories for very long hours, sometimes amounting to 2,000 hours per annum. In these cases the electric light can be used by the manufacturer himself at an equal, and in some cases even at a lower price, than that of the town gas; therefore, the longer the hours of work the more favourable to the electric light.—Yours, &c.,

R. E. CROMPTON.

London, E.C., June 25th, 1884.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have much pleasure in acceding to the request of your correspondent, Mr. W. C. Martin, that I should give the figures on which my statement was based, that the cost of electric lighting in a mill in which the necessary power can be taken from existing engines is very approximately the same as the cost of gas lighting. I took the general case of a mill requiring a light equivalent to 500 20 candle-power burners, and as the basis of the calculation I assumed (as was fully stated in my lecture) that the lights would be required during 500 hours in the year.

The prime cost was then estimated as follows:—

	£	s.	d.
Dynamo and fittings	£550	0	0
Lamps, 500 at 4s.	100	0	0
Wiring, including holders, cut-outs, switches, and labour	250	0	0
	£900	0	0

As I had no particular case in mind the item for wiring was necessarily little more than a guess. I am glad to find, however, that it agrees well with the corresponding part of the estimate Mr. Martin quotes as having been calculated by him for an actual mill using 500 burners.

For the annual cost we have:—

	£	s.	d.
Interest on £900 at 4½ per cent.	£40	10	0
Depreciation of the dynamo, at 8 per cent. (on £550)	44	0	0
Depreciation of the wiring, at 4 per cent. (on £250)	10	0	0
Renewal of lamps, 250 at 4s.	50	0	0
Coal:—60 h.-p. for 500 hours, requiring 3lb. of coal per h.-p. per hour, with coal at 8s. per ton	16	0	0
Oil and attendance, say	6	0	0
	£166	10	0

Now to get an equal amount of light from Dundee gas we must burn 4 cubic feet per hour in each burner, or $4 \times 500 \times 500 = 1{,}000{,}000$ cubic feet in the year. This, at 3s. 6d. per 1,000 cubic feet costs £175, which the Gas Com-

missioners' discount of 5 per cent. for prompt payment reduces to £166 5s. If my figures are right, gas and electricity, in the circumstances we have here, cost the same.

I do not think that serious exception can be taken to the items given above for the prime and current cost of the electric installation. For the prime cost my figures agree substantially with Mr. Martin's, except as regards the dynamo. He estimates for three machines, and puts their cost at £700. I should prefer a single 500-light machine, not only on the grounds of economy and simplicity, but because it does away with the necessity of high speed driving. For a well-built dynamo running at five or six hundred revolutions per minute, and in the charge of a skilled engine-driver, a depreciation rate of 8 per cent. is surely liberal; and the item for attendance has to cover nothing more than part of the time of a boy who replaces broken lamps.

Mr. Martin tells us that the yearly gas bill of the mill he refers to is only £100. I know the mill in question. It is one which, on account of both its position and its construction, requires exceptionally little artificial light. Besides, there can be little doubt that the 520 lamps in Mr. Martin's estimate would give a total illumination considerably greater than that given by the existing 500 gas burners.

The only important part of my estimate which I can regard with mistrust is the assumption of 500 hours as the time during which artificial light is wanted throughout the year in an average mill. If the actual number of hours is less than 500, the cost of gas will be reduced more than the cost of electricity, since the items for interest and depreciation remain unchanged.

Precise statistics of the number of hours per annum during which gas is burnt in the Dundee mills are not easily obtained, but it appears certain that the number is, in ordinary cases, over 400.

If we assume 400 hours instead of 500, the cost of gas is reduced (by one-fifth of £166 5s.) to £133. The cost of electric lighting is reduced (by one-fifth of £72) to £152. In that case, then, electricity will be somewhat dearer than gas, but the difference is too small to outweigh the many advantages of the new illuminant. And the assumption of no more than 400 hours' use per annum is the least favourable to electricity which, in these northern latitudes, it seems permissible to make.—Yours, &c., J. A. EWING.

University College, Dundee, June 24, 1884.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It would have added considerable value to Mr. Martin's remarks in his letter of this week's issue if he had given the price of gas at Dundee, and the average time of lighting per diem. Taking his figures, 500 gas jets for £100 per annum, obviously gives us the cost of one jet as 4s. a year, or roughly 1d. per week. Supposing the burner is lighted for six hours a day, consuming 5 cubic feet of gas per hour, this would make the price of gas at Dundee at 6½d. 1,000 cubic feet—an altogether incredible figure. Or taking it another way, assuming the price of gas to be 1s. 10d. per 1,000 cubic feet, the gas must be lighted for an average of only two hours a day.—Yours, &c., W. T. GOOLDEN.

21st June, 1884.

THE BARROW-IN-FURNESS INSTALLATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the report of an installation of electric light at the Criterion Restaurant, Barrow-in-Furness, published in your issue of 21st inst., you express an opinion that the "Phœnix" dynamo machine is identical with the "Lumley." Kindly allow us to point out to you that you have been misinformed. The machines are not alike either in outward appearance or internal construction. The special point claimed in the "Lumley" patent is that the interior projections of armature plates are provided to carry off the heat generated in armature. These are not found in the "Phœnix." This is one difference between the two machines, and there are many others. We shall be most happy to show you the two machines if you will favour us with a visit to our works, when you can judge for yourself. Trusting that you will find space for this in your next issue.—Yours, &c.,

PATERSON and COOPER.

St. Paul's Telegraph Works, 76, Little Britain,
London, E.C., June 24, 1884.

INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In M. Gallice's letter to *L'Electricien*, quoted in this week's *Electrician*, he mentions the appearance of a violet coloured glow in the lower part of the filament in a Gérard incandescent lamp; and speaks of such an appearance as a remarkable phenomenon, inferring that it indicates a better exhaustion of air than is found in other lamps. I do not think that such an appearance as he speaks of is a peculiar characteristic of the Gérard lamp. No doubt many electricians have witnessed this phenomenon with regard to other incandescent lamps. I can say this with some assurance, having seen this effect take place in a Lane-Fox lamp, which was being very severely tested. The lower part of the filament became of a bright violet colour, just as described by M. Gallice.—Yours, &c.,

A. T.

London, W., 20th June, 1884.

THE RISE IN TEMPERATURE OF ELECTRIC LIGHT LEADS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Taking the formula

$$t^0 = \frac{4\rho}{J h \pi^2} \cdot \frac{C^2}{d^3}$$

given in Munro and Jamieson's "Pocket Book," and substituting for the symbols in the left-hand portion of the formula the values given in this work, viz.,

$\rho = 1700$
$J = 4{\cdot}2 \times 10^7$
$h = 2 \times 10^{-4}$ (for bright copper)
and $\pi^2 = 9{\cdot}8696$,

I obtain the following expression:—

$$t^0 = \frac{C^2}{d^3 \times 12{\cdot}192} \text{ in degrees centigrade.}$$

The value d being taken in centimetres, this expression would appear to be altogether erroneous.

Perhaps the authors of the "Pocket Book," or others interested in the question, would kindly point out where the error resides?—Yours, &c., STUDENT.

TAKING OUT THE STAIN OF SULPHURIC ACID.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I would be much obliged if you could let me know through your correspondence column whether there is any way of getting the stain of sulphuric acid out of marble, as a small secondary battery has unfortunately been upset over a marble mantelpiece and stained it very badly.—Yours, &c.,

H. M. T.

CHLORIDE OF SILVER CELLS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am trying to make a chloride of silver battery, but do not know how to fuse the chloride round the rod of silver. Kindly state in next number of *The Electrician* how to get fused chloride of silver cast on a block of vulcanite which has silver foil rolled round it.—Yours, &c.,

THE COST OF ELECTRIC LIGHTING.

Figures, it is often said, may be employed to prove anything—except facts. The use of figures to prove certain foregone conclusions in electric light operations is no exception to this rule. A question frequently asked of late relating to the continued dulness in electric light work is now being partially answered in our "Correspondence" columns. Leaving for the moment this important discussion, let us attempt to put the case as it presents itself to us. The progress of science has introduced a new system of artificial lighting; but another and by no means a bad system of artificial lighting is in the field—in fact, holds possession of the ground. The work of the supporters of the new system is principally that of ousting the old system. Where no artificial light has ever been used, and where the surroundings do not lean to the one system rather than the other little difficulty is encountered in persuading the users to adopt that system which science and common sense pronounce to be best. Under ordinary circumstances, houses, mills, &c., come into the possession of the occupiers with the gas fittings almost or quite complete. A certain amount is paid for fixtures, which amount the householder or proprietor proceeds to forget as soon as paid. It is an incidental tax levied when there is a change of residence. The same remarks that hold in this case will hold whatever the new introduction proposed may be; and not only do they hold in the case of lighting, but in almost all cases of expenditure in ordinary life. Users of steam engines are not generally eager to throw out the engines in use in order to supply their places with other and, it may be, more economical engines. They prefer to wait till the existing apparatus must be replaced, and they replace it by the most modern type in the market. The same will hold good with gas and the electric light. There are times and places when the former must be replaced, and thus comes the chance of electricity. This we contend is the normal condition of affairs, and if no other condition existed, the introduction of anything new would be an almost impossible task. Two most important factors in human affairs are luxury and fashion. Indulgence herein means putting aside the hard and fast commercial considerations, which might otherwise be expected to regulate the human hive. In the case of artificial lighting, as in other things, that which is shown to comply best with the requirements of luxury is indulged in by the luxurious. Fashion follows in the wake of luxury and increases the demand. The increase in the demand leads to increased competition and diminution of first cost, putting the apparatus within the reach of a wider circle of users. We have not considered the case in which the circumstances are altogether in favour of the new introduction, because such cases are few in number and altogether exceptional.

Let us see how the theory agrees with the facts. A few years ago dynamos and lamps cost far more than at present. Manufacturers and patentees are not philanthropists. They work for a profit, and if the demand for their goods is small, a large sum must be added to the prime cost of each machine to make it worth while to make it at all. The increased demand leads to putting down new machinery, diminishing the prime cost, increasing the output, and lessening the price to the consumer. Lamps which a few years ago cost a pound a piece can now be bought for less than five shillings each, and we fancy the cost of dynamos is less than half what it was say at the time of the Paris Exhibition. It is quite evident that the manufacture of electrical apparatus is not the lucrative business that we are led by many to suppose; at any rate, the commercial standing of the companies is not altogether in favour of the lucrative view. Having thus briefly viewed the question from the manufacturer's standpoint, we will now discuss the interesting letters in our "Correspondence" columns. Comparisons are, we know, odious, and especially is it so between gas and electricity. If in such a comparison we keep entirely to figures, the result is very misleading, because electricity presents so many advantages that cannot then be brought into the comparison. It has become customary, however, to make such comparisons, and hence we may take them for what they are worth. The cost of gas per annum is not stated upon the gas bill. To the bare amount paid to the gas company must be added depreciation and interest upon fittings, depreciation upon decoration, and so on. If we have to consider an entirely new installation of gas or of electricity, we are prepared to submit that the cost of the fittings in the house and the cost of conduction from the point of generation to the point of usage are not more in the case of electricity than in the case of gas. Will any one be bold enough to say that the cost of a central electric light station is more than the cost of a central gas station? This brings us to the question of burning coal to produce electricity as against the burning of

Digitized by Google

coal to produce gas, and after all we maintain this is the crucial point.

An isolated installation is hardly a fair test of cost in any case. Mr. Crompton and Professor Ewing point out that the time during which the artificial light is required is a most important factor in the result. It matters little to a gas company whether 500 burners are in use 500 or 300 hours during the year. The average consumption of gas over the whole district is the standard by which their actions are guided. In the case of separate installations, however, whether of gas or of electricity, of 500 burners, the number of hours is of the greatest importance. A question raised by Professor Ewing needs elucidation, and a good deal of information might easily be given. What is the percentage of renewals of lamps? Fifty per cent. per annum seems enormous. Is this estimate founded upon practical work? We have again and again asked users as to the loss of lamps, but have always understood that the percentage of renewals was far below the estimate given by Professor Ewing when the number of hours of burning during the year do not exceed five or six hundred.

THE ELECTRIC LIGHT IN FLOUR MILLS.*

BY J. H. GREENHILL, OF BELFAST.

After explaining the difference between the electricity produced by friction machines and that produced by batteries, Mr. Greenhill proceeded to explain the construction of a battery and dynamo, interpolating a considerable amount of elementary matter for the benefit of his audience, with which we need not trouble our readers, though doubtless it was well appreciated at Stockton. In speaking of dynamos, Mr. Greenhill said :—I have constructed a machine specially for this meeting, which is the first of its kind, and I hope will do credit to its maker. It consists of magnets made up of an immense number of thin sheets of charcoal iron; upon these are placed coils of fine insulated copper wire, of which there is over half a mile. The rotating armature is joined to plates of brass termed a "commutator," from which the electricity is collected by brushes or strips of copper. The armature is driven by a belt from a large fly-wheel operated by means of two winch handles. This little machine is capable of supplying current for eight lamps of 20 candles each, or one small arc lamp; however, as we only can apply the power of two or three men, the utmost they can turn will supply currrent for five lamps of 20 candle-power each, as it requires slightly more than half of a horse-power (indicated) for this number, and even with these the men are not able to maintain the speed to keep the lamps to their full brilliancy. The incandescent lamps here exhibited are Swan's, Woodhouse and Rawson's, and Burnstein's. Having described the principles of arc and incandescent lighting, Mr. Greenhill said a few words on the storage of electrical energy, and then proceeded to give some details as to the cost of lighting mills, which we think will be of considerable interest to our readers at the present moment. He said :—With reference to the relative merits of the electric light compared to other means of artificial illumination, the main question is How does it compare with gas in cost? To answer this, various considerations have to be taken into account. First—What is the price of gas and its illuminating power? Further, what means are there for driving the electric light machine? Well, to arrive at perfectly unbiassed opinions, let us take gas at 2s. 6d. per 1,000ft. and of 17 candles illuminating power, and we will suppose the comparison has to be made as to relative cost in a flour mill with 100 lights of 20 candle-power each, or an aggregate light of 2,000 candles. To obtain this light by gas it will take 590ft. per hour, and to this must be added leakage during the day, or if the gas is turned off, the refilling of the pipes, which I think may be taken at 1 per cent., or say in round numbers 595ft. of gas per hour.

	s.	d.
Cost of which at 2s. 6d. per 1,000ft. =	1	5¾
Cost of repairs to pipes and renewal of burners £6 per annum = ¾d. per hour (2,000 hours)	0	0¾
Attendance 5s. per week = £13 per annum = 1½d. per hour	0	1½
Interest on first cost, say £50 at 5 per cent. = £2 10s.	0	0¼
Cost of gas per hour	1	8¼

Or for 2,000 hours £168 15s.

Electric light—100 lights of 20 candle-power each = 2,000 candles—

	s.	d.
Power required, say 11 indicated horse-power at 3lb. of coal = 33lb. at 10s. per ton	0	1¾
Renewal of lamps, taking average durability at 1,500 hours represents 1 lamp for every 15 hours to be renewed, costing 5s. = cost per hour	0	4
Attendance 5s. per week = £13 per annum = 1½d. per hour	0	1½
Oil and waste 3s. 6d	0	1
Interest on first cost, say £300 at 5 per cent. = £15. per annum	0	2
Repairs of machine, &c., and depreciation 5 per cent. on £130 = £6 10s	0	0¾
Cost of electric light per hour	0	11

or for 2,000 hours £91 13s. 4d., thus showing an annual saving over gas of £77 1s. 8d.

Now, lest it should be considered that this is too favourable an estimate for the electric light, I have obtained from Messrs. Furlong and Sons, of Lappsquay Mills, Cork, who were the first to permanently adopt electricity in Ireland, the result of their experience. The gas in Cork is 3s. 11d. per 1,000ft., and therefore it is considerably in favour of the electric light; but it will be observed that the saving is so great that, even if gas had been as low as 2s. 6d., the results would entirely have borne out my calculations. Messrs. Furlong's installation consists of 50 lights equal to 20 candles each, or just one half what I took as a basis for our calculations. Their gas bill was as follows :—

	£	s.	d.
In the year 1877	161	0	6
,, 1878	192	3	1
,, 1879	136	6	7
,, 1880	142	8	5
,, 1881	114	17	11

The illuminating power of the gas is 18 candles. It will be observed there was a great falling off in the cost between the years 1878 and 1879, arising from alterations in their gas arrangements, and the adoption of a gas regulator. The electric light was put in at the end of 1881, with the following result:

	£	s.	d.
Renewing lamps per annum	19	15	0
Repairing an accident to machine	7	0	0
Renewing brushes	1	5	0
Oil and waste	1	0	0
	£29	0	0
Paid for gas while mill was idle	12	10	0
	£41	10	0

Nothing was put down for interest and coals; but personally I am able to calculate these pretty clearly, and they amount to £20 8s., which added to £41 10s. = £61 18s.

Messrs. Furlong have not calculated the renewal of gas appliances, nor have they added cost of attendance in either case. Hence the saving to them has been considerably over £60 per annum. They run the machine now day and night.

I have also received reports from Messrs. Hall and Co., of Cork, who have used the electric light in their mills for about two and half years, in which they state that they now save about 70 per cent. of their original cost of gas; further, that the electric light has given complete satisfaction. However, in their report they do not estimate anything for power, as they consider it so trivial as not to be noticeable on their engine, but they add that they consider the electric light is an incalculable advantage to flour millers considering it minimises the risk of fire, and reduces the temperature of the mill very much. Messrs. Furlong and Sons, of Fermoy, have also written to me most favourably of the electric light, which they have had in

* Abstract of a paper read before the National Association of British and Irish Millers, at the Millers' Convention, at Stockton-on-Tees, 24th, 25th, and 26th June, 1884.

Digitized by Google

operation for about fifteen months, and the saving in their case compared to gas has been very great. They also report many of the lamps originally put up still in perfect condition after having worked 3,756 hours.

It will be observed that I took an average of 1,500 hours as the durability of the lamps; some would not last so long, while others would, and have far exceeded this period, and as the renewals of the lamps appear in my calculations the heaviest item, it follows that if they last longer, or become cheaper in cost, which we may reasonably expect, the expense for electric light in flour mills will be still further reduced.

There are many firms of flour millers now using the electric light throughout the country of whom I have not heard, but I have been favoured by Mr. Wilson Hartnell, of Park-row, Leeds, who is the agent in Yorkshire for Messrs. R. E. Crompton and Co., with the following list of installations erected by him, under the superintendence of Mr. Farrar:—

Messrs.	Reynolds and Haslegrave, Wakefield	50 lights
,,	Robinson and Hanley, Doncaster	50 ,,
,,	W. and J. Bairstow, Keighley	62 ,,

The following is a list of the installations which I have erected in flour mills in Ireland.

Messrs.	Furlong and Sons, Cork	50 lights.
,,	Hall and Co., Cork	50 ,,
,,	Furlong and Sons, Fermoy	64 ,,
,,	A. R. Walker, Newry	62 ,,
,,	D. and W. Carmichael, Belfast	64 ,,
,,	Bannatyne and Sons, Limerick	120 ,,

In conclusion, I have only to direct attention to the safety of electricity from fire with properly erected installations, compared to gas. Personally, I do not consider there is one-fourth the risk of fire from the electric light; matches and naked lights are not required, and besides these points, the air remains perfectly pure in the mill, thus adding to the health and activity of the workmen. With respect to danger to life by using electricity, there is practically no danger whatever in using direct current machines of low tension, such as are employed for incandescent lighting, nor is there much, if any, danger with arc light machines, presuming that it is not required to have too many arc lights driven off one machine.

HIS ELECTRIC FITTINGS.

BY MHO.

About four o'clock on a Wednesday afternoon of December, 1883, Mr. William Lightearnest was plodding his way along the West Strand, when he accidentally met, face to face, an old college chum of his, named John Doughty Thump.

"Well, upon my word, Thump, you were about the last man whose path I dreamt to cross at this precious moment. Whatever have you been doing with yourself during the year?"

"The question, my dear boy, is somewhat of a puzzle. Have been for a climb over the Alps, then for a walking tour through Brittany; and lastly to Madrid for the bull-fight season, whence I returned out of humour with myself and the world, fully determined to kill the rest of the year in riding, shooting, lawn tennis, and other health-giving and lawful pursuits. In this converted temper I followed the crowd to the Fisheries Exhibition, but failed to distinguish you in that wonderful collection. Still, presume you went there with the sum-totum of civilised peoples."

"Yes, several times, always finding it full of scientific interest. The ship models were very fine, and the fishing tackle, especially the delicate meshing in the Norwegian Court, splendid. Then, again, the vast number of curiosities related far and near to the fishing industry were extremely rare."

"Decidedly rare," echoed Thump; "and, to tell you the truth, I was more interested in the Fisheries than I am usually in such scientific displays, which, as you know, generally bore me to death. The constant staring inflames my eyes, the kaleidoscope of objects worries my brain, and the slow locomotion invariably gives me a wretched ache in the spine. But there was much at the Fisheries to compensate for all this martyrdom. There was that old craft of Grace Darling's, reminding one so forcibly of womanly pluck, and teaching us that men have no monopoly of the quality. Another thing which took my fancy was that Irish cockle-shell thing, comparable only to a wrecked and dissolved Christmas hamper But there, with my habitual selfishness, I am dilating upon my own doings and forgetting all about your sport. Come, what has kept *you* secluded for the whole year?"

"Unconsciously imitating your example, I have been on the Continent, visiting the exhibitions at Amsterdam, Munich, and Vienna."

"On some scientific hobby, I infer?"

"Yes, in search of the best forms of electric fittings."

"So you are bent upon fitting up your place of business with the new-fangled light."

"No, my private residence down at Chudleigh. *En passant* if you can run down next Monday afternoon I shall have much pleasure in showing you over the old place under a new light."

"Most willingly, my good friend, but first let me see if that fits in with my other engagements. To-morrow (Thursday) I go out practising with my volunteer corps; Friday I hope to run down and have a look at that Weston fellow on his long walk; Saturday I trundle over my customary thirty miles on my bicycle; Sunday, well I will not divulge what I ought to do on that day; but on Monday afternoon I will most certainly visit Chudleigh, and inspect your electric fittings."

"Thank you, and therefore agreed. My brougham and I will be in attendance on the four o'clock train, so for the present, *Auf wiedersehen, mein freund!*"

"A good bargain, so till we meet at Chudleigh, good bye!"

The above dialogue affords ample evidence that William Lightearnest and John Doughty Thump had cultivated decidedly opposite tastes; still, as often happens, they had become, in spite or more truly perhaps because of their dissimilarity of temper, very intimate friends.

Lightearnest was of a studious and scientific turn, a little pedantic in his ways, and fond, as you perceive, of spicing his conversation with quotations from other languages. John Doughty Thump was a full-blown, large-minded specimen of muscular christianity, whose style of conversation sufficiently betrays his character, and therefore relieves us of the onerous duty of describing his salient points.

The appointed Monday came, and as arranged Thump took his departure by the afternoon train for Chudleigh, where on arrival he entered his friend's brougham, and was immediately carried in the direction of Chudleigh House—a fine model of a suburban residence, surrounded by extensive acres of its own, and approached by a long straight drive, lined on each side by towering elms, which extending their huge arms in mutual embraces formed a green canopy between the road and heaven. A lodge stood at the opening of this avenue, and over the gateway was suspended a monster arc lamp, shedding its bright lustre over hedge and pasture, and clothing the vicinity in a soft moony glow.

As the brougham shot under this brilliant circle of light, Thump looked enquiringly into his friend's face, as if he would ask what all the illumination meant. But Lightearnest at once broke the spell.

"Do not perplex your mind, my dear good fellow, it's only the light of the arc lamp over the lodge gate."

"But what are all those illuminated hour-glasses on each side of the way?"

"Why, they are incandescence lamps, my dear friend. You must have seen lots of them at the Fisheries."

"Now you mention it, I remember I did. But I say, this electric light business must cost you a nice penny."

"Not at all, I find it quite as economical as gas, and for equal cost the light is three to five times as powerful."

"Is that really a fact? By the way, what kind of a light is this in the carriage, just above our heads?"

"If you turn you will see it is one of your little hour-glasses."

"Impossible! There is nothing to show how the light is produced. You don't mean to say it burns like a tallow candle?"

"I will explain it to you if I can. First we pass a current of electricity through the carbon filament, which under this

Digitized by Google

influence gradually becomes incandescent, with an illuminating power equal to twenty of your tallow candles, or, if you prefer the definition in terms of horseflesh, each lamp represents one-eighth the estimated strength of a horse.

"Yes, but where do you get the electricity from? I see no machinery about."

"No, you are sitting on it."

"On what?" And poor Thump involuntarily stood up and looked expectantly down upon the smooth carriage cushion.

"Oh pray sit down, my dear old boy, I only meant to tell you that the accumulator, or charged battery, is contained within the box under your seat. You needn't be alarmed; there is no danger of you receiving any violent shock to your system. Altogether there are three incandescent lamps to the brougham, one as you see inside and two side lights out."

At that instant the brougham drew up at the hall, and Thump, bent upon being polite, rose to open the carriage door.

"Allow me, my dear fellow," said Lightearnest.

"Pardon me, I would rather——"

"But be patient for one moment, and please keep your seat. Now, be kind enough to press that button facing you."

"Thump mechanically pressed the button, and the carriage door flew wide open."

However do you manage that?" exclaimed Thump.

"Oh, it's all done with the help of the accumulator, an electro-magnet, and a small iron armature, which, on pressing the button and setting the current going, is attracted by the poles of the magnet."

"But I see no current, nor magnet, nor furniture. What did you say the last thing was?"

"Do you see the handle of the door?"

"Yes."

"Well, that is the electro-magnet, and the armature is hidden out of sight near what looks like the keyhole of the door."

The two friends had by this time reached the hall door.

"I dare presume you will allow me to ring?" said Thump.

"Not the slightest necessity for that antiquated practice. Will you kindly press that button on your right?"

Thump obeyed, and the door opened as of its own accord.

"But I say, Lightearnest, what marvellous things these buttons of yours must be!"

Lightearnest laughed, and patronisingly patted his friend on the back.

Thump paused awhile on the door mat, mechanically rubbing the dirt off his boots, but his host assured him that this time-honoured and cleanly custom was quite out of fashion at Chudleigh.

"Just plant one of your feet on the mat."

Thump did so, and the mat at once began a to-and-fro movement across the floor, cleaning Thump's boot in a most masterly and shoeblack-like style.

"Now the other foot."

Thump silently acquiesced, and then looked down on both boots to find them spotlessly clean.

"I call that a most wonderful piece of trickery, and I should be happy to patronise the principle if I only understood the knack of it."

"Oh, you shall understand it all by and by. Meanwhile, content yourself with the reflection that the old-fashioned proceeding of 'rubbing one's shoes on the door mat' has seen its day, and here at least is considered to be a thing of the past. In future we are determined that the mat shall honour the shoe, just as the discovery of Galileo forced our pigmy earth to take a diurnal plunge in the light of the sun, forbidding this dignified luminary ever again to sweep out gigantic circles about our insignificant centre."

Lightearnest then led his friend to the smoking room, the door of which, as usual, flew open under the magic pressure of the thumb. The apartment was duskily lit up by a series of what the neo-scientific Thump characteristically termed "red marks." But as soon as his host turned a small switch standing on the table these "red marks" gradually changed into brilliantly white incandescent streaks of light. Thump, thunderstruck, mumbled to himself something inaudible about the colours of the setting and the splendour of the noonday sun.

"Allow me to offer you a cigar."

"Thanks, old boy. Now please give me a light, and if not inconvenient a new-fangled one."

Thump gave a farewell chuckle to this request, thinking that he had at length "set a poser."

"As you wish it so much I will try to arrange one for you," and Lightearnest drew forth a small tin match box, which he held close under Thump's eyes, asking him to look at it attentively. As Thump gazed at this contrivance there gradually arose before his astonished vision a coil of "dull red marks," which in turn became metamorphosed into a brilliant fold of light.

"There, my good friend, you can now tip the end of your weed with pure Promethean fire."

It need not be said that by this time poor Thump's mind was in a state of wild bewilderment. Sinking into an arm chair, he besought Lightearnest "just to let him into the particular go of this button business."

"Moreover, I should be extremely obliged to you if you would explain away a little of the mystery of all these puzzling phenomena, sedulously avoiding big words, scientific jaw-breakers, and those foreign tit-bits of yours, which will only bamboozle my mind the more."

"The task you set me is not so easy as it looks. But I may tell you that the amusing electric effects which you have so far seen are all due to one great physical fact, namely, that if you pass a current of electricity through a coiled magnet, and at the same instant place a piece of iron called an armature in front of the poles of the magnet, the latter will draw the armature towards itself, and hold it fast. As a boy you must have often played with a red magnet and a needle. Well, a coiled magnet under the influence of an electric current attracts the iron and lets it go again in precisely the same fashion. Now this current is set in motion or cut off by pressing or releasing the button. Imagine, then, the latch of the carriage door to be the needle or armature, and you will understand how the attractive power of the handle-magnet helps to withdraw the latch and open the door. In a similar way the to-and-fro motion of the door-mat was brought about by the making and breaking of contact of an electric circuit, which produced a corresponding reciprocating movement in an armature working in a rectangular hole or slot and attached to the under surface of the gutta-percha matting. This reciprocating motion of the mat is beautifully expressed in French as *un mouvement de va-et-vient*; in German by *eine hin und her bewegung*; and in Spanish by ——.

"Thank you very much," interrupted Thump; "the new light was just beginning to dawn upon me. So all this is derived from the red magnet and needle business. The times I have made that old red horseshoe run off with poor grandfather's steel nibs and mother's darning needles!"

"I'm glad I've made the matter so clear to your mind. Circular motion is obtained in a similar way. You have only to remember that if the poles of a magnet be opposite, or in other words, one north and the other south, they will attract each other; whereas if they be alike—that is, both north or both south—they will mutually repel each other. Hence, if you have a round armature enclosed between a number of alternately north and south poles, it follows that once the armature is started it will continue to revolve, because any part of it is constantly being repelled by one and attracted by the other pole.

"That's all done on the peg-top principle, I suppose," suggested Thump.

"No, not at all."

"Well, be that as it may, I remember that when we used to play at that juvenile game it was necessary to have a 'coil' of string and an iron spike, which I would modestly venture to match against your coiled magnet and iron armature."

"But, my dear good boy, peg-top velocity is due to a mechanically applied force, tangenial to the conoidal surface of the top; whereas the revolution of an armature depends upon the principle of alternate attraction and repulsion."

Thump stretched his long legs, protested against the attempt to floor him by big words, and gave expression to the gravest

Digitized by Google

fears that some kind of circular motion was at that moment going on within his own brain.

"Then perhaps you might find relief in a stroll round the garden."

The two friends at once rose and sauntered down the paths of the large garden. The subject of electricity gave place to more ordinary topics of conversation. Reminiscences of college days were exhumed and re-discussed with all the vehemence and enthusiasm of youth. Suddenly, however, Thump's attention was arrested by a draw-windlass over a well, which stood at the end of one of the walks. "By Jove, Lightearnest, the axle of that winch is turning round without the aid of man, or other agency."

"Yes, I see it is," said Lightearnest, but you know the old Latin philosopher insists upon it—'*Ex nihil fit nihil.*'"

"Then, may I ask, where the deuce is the man at the wheel?"

"He stands by your side."

"What you?"

"Yes."

Thump's thoughts reverted to the magic buttons, and after a minute search he discovered that a kind of lever was concealed, and being pressed under his friend's right foot.

"There, in that winch," said Lightearnest, "you have an example of circular motion produced by the action of an electric current."

Thump stared mutely at the contrivance, saw it lift and tip a bucket of water, and then solemnly adjudged it to be "quite a marvellous piece of mechanism"—after which scientific outburst the two friends returned to the house in obedience to the fingers of the tower magnetic clock, which marked the dinner hour.

Dinner over, Lightearnest invited his friend to a game of billiards, in which the marking was done by pressing any one of a series of buttons fitted into the flat edge of the table frame. Thump expressed no surprise at this clever adaptation, for he was now prepared to regard buttons as containing the latent solution of every conceivable problem. Therefore he applied his thumb with all the well-poised complacency of a *connoisseur*, declaring that he considered the new button a vast improvement upon the old finger-marker.

But now a cursory glance at his watch warned our guest that it was growing late. He had barely time left to catch his last train; so rushing down into the hall, he hurriedly cast on his overcoat and seized hold of his hat, which he discovered required a little trimming up.

"Could you, Lightearnest, as a last favour, oblige me with a hat brush?"

"Certainly, will you kindly insert your hat into that hollow cylinder thing?"

Thump obeyed, and the hollow brush began at once a series of revolutions, bringing out upon the hat a gloss which, enhanced by the reflected light of the arc lamp in the hall, fairly dazzled the wondering eyes of our departing friend.

"Well, I am loth to leave you and your fairy mansion, but it is so fated; good-by, and many thanks for the amusement your new fittings have afforded me."

"*Adios, amigo mio! Omne tulit punctum qui miscuit utile dulci.*"

John Doughty Thump then entered his friend's brougham, and was wheeled off to catch his train, vowing as he went that it would be a long time ere he forgot his marvellous experiences at Chudleigh House.

CURIOUS ACCIDENT BY LIGHTNING.—During a storm at Greenville, Rhode Island, U.S., on the 9th May, says an American paper, the lightning ran by the telephone wire to the Windsor Mill, where there is no telephone, but the wire is disconnected just outside the building. The lightning was led by the wire to the corner of the mule and weaving rooms, and entered the building under the jet. It followed the water pipe and set the sprinklers going, and at the same time fired the stock in the mules. By this singular provision of an active extinguishing agent at the moment the fire started serious loss was prevented, as the fire was soon drowned out.

CITY AND GUILDS OF LONDON INSTITUTE.

The following questions were set at the recent examinations:—

PAPER 22 B.—*Electric Lighting and Transmission of Power.*

ORDINARY GRADE.

[*Candidates are not to answer more than two out of the first three questions, and not more than seven questions altogether.*]

1. What is the difference between the electromotive force of a battery and the potential difference maintained at its terminals? Explain how it is that when a generator of electricity is employed to send currents through a number of parallel circuits, the current passing through any one of these circuits is practically independent of the currents passing through the remainder, if the resistance of the generator is small compared with that of the circuits.

2. Explain fully what is meant by saying that a body has a large electric capacity. The tendency of an electrified body to lose its charge can be increased by attaching a metallic point to it. Does this alter the capacity of the body? Give your reasons for your answer. What exactly do you understand by the statement that the joint resistance of two parallel wires is equal to the product of their resistances divided by their sum? Define an ohm, ampere, volt, coulomb, and farad.

3. How does the electricity produced by an electric machine differ from that produced by a battery, and how can a battery be made to produce the same results as an electric machine?

4. Thirty accumulators, each having an electromotive force of 2·1 volts and a resistance of 0·002 ohm are employed to feed incandescent lamps. If the lamps require 45 volts and 1·25 ampere each, what is the maximum number of lamps that can be employed?

5. What is meant by the characteristic curve of an electric generator? Draw the characteristic curve for a battery, a series dynamo, a separately excited dynamo, and for a shunt dynamo.

6. The speed of a dynamo is kept constant while the external resistance is gradually diminished. Explain how the electromotive force, and how the potential difference at the terminals vary:—1st, when a series dynamo; 2nd, when a shunt dynamo is employed.

7. Explain how it is that when a gas engine is used to work a *shunt* dynamo to charge accumulators the gas engine may be started by the current from the accumulators working the dynamo as a motor, and so that when the gas engine has got up speed the dynamo will now charge the accumulators; and show why this cannot be done with an ordinary series dynamo.

8. When lamps are fed in the ordinary method in parallel circuit, show how to calculate the falling off in potential difference as we proceed along the mains. Describe a method of arranging the mains so that the potential difference maintained between the terminals of a number of lamps in parallel may be the same throughout the whole circuit, and show how the gauges of wire that must be employed for the various portions of the main conductors may be calculated.

9. A room containing 60 lamps, each requiring 80 volts, is at a distance of 200 yards from the dynamo; what must be the diameter of the copper of the main leads so that the potential difference at the lamps is not less than the potential difference at the terminals of the dynamo by more than 1 per cent.—1st, when the lamps require 45 volts; 2nd, when they require 110 volts? One yard of commercial copper wire one square inch in section has 0·00002435 ohm resistance.

10. How can the direction of rotation of an electro-motor be reversed—1st, if it be a magneto motor; 2nd, a series motor; 3rd, a shunt motor? Give a drawing of a good speed-reducing gear to be used when a motor is required to drive slow-moving machinery.

11. Describe in detail the construction and use of a photometer suitable to be used with an incandescent light and a photometer for an arc light. What variation occurs in the

Digitized by Google

illuminating power—1st, of an incandescent light; 2nd, of an arc light when viewed through red and through green glass? How does the intensity vary for beams at different angles in the same vertical plane for arc lights and for incandescent lights—1st, when a continuous current; 2nd, when a reverse current is employed?

12. What is meant by the "lead" in the brushes of a dynamo and a motor? Show exactly when it is necessary to alter the lead for a series dynamo and for a shunt dynamo. Apply your answer to question 7, and consider whether the lead should be the same for the shunt dynamo when running as a motor and when subsequently charging accumulators.

---

22 C.—*Electrical Instrument Making.*

ORDINARY GRADE.

[*Candidates are not to answer more than two out of the first three questions, and not more than seven altogether.*]

Questions 1, 2, and 3 are the same as in the preceding paper, 22 B.

4. The deflection of the needle of a galvanometer is not as a rule proportional to the strength of the current. Describe in detail various methods of ascertaining experimentally the connection between different currents, and the deflections they respectively produce. Show clearly what is the least amount of apparatus you must employ for carrying out each method. In what way would it be best for a galvanometer maker to record, for the benefit of the purchaser, the law connecting deflection with current?

5. Give a drawing, with detailed description, showing the construction of a dead beat galvanometer, and of a galvanometer the readings on which are not affected by external magnetic charges. Describe generally the various ways in which a galvanometer can be made so that the deflections shall be directly proportional to the current.

6. How would you make a cheap resistance, the magnitude of which could be altered at will, to be used for strong currents? Give a drawing of the details, and a specification for the guidance of the maker.

7. A bobbin measuring 2in. between the end cheeks, and having an internal and external diameter respectively of ½ and 1½in., has to be wound. What length of wire, the diameter of which, including its insulating covering, is 0·012 of an inch, would be required to fill the bobbin?

8. A potential difference of 50 volts maintained at the terminals of a galvanometer wound with a resistance of 1,000 ohms produces a deflection of 45°. If the existing coil be replaced by another of exactly the same size and shape, what must be its resistance so that a potential difference of 120 volts may produce the same deflection with the same controlling magnetic field? Compare the heating of the bobbin in the two cases if the deflection of 45° be maintained for a considerable time.

9. Give a drawing of a charge and discharge key having high insulation, and write a specification such as should accompany your drawing if you were ordering such a key to be made.

10. What brand of steel is the best to be used for making permanent magnets? Describe *fully* how the steel should be hardened, and how magnetised, so as to produce—first, a very powerful magnet; secondly, a magnet whose strength would alter very little by time. In what way would the size of the magnet to be made modify your answer?

11. Describe fully the best method of joining together two thick pieces of gutta percha covered cable, so as to ensure good conductivity of the conductor, and good insulation of the gutta percha at the joint.

NUMBERS OF "THE ELECTRICIAN" OUT OF PRINT.—Vol. I., Nos. 3, 9, and 19; Vol. VII., 1, 4, 6, 8, 10, 12 to 18, 20, 21, 24, 25, 26; Vol. VIII., 1, 3, 6 to 26; Vol. IX., 2, 3, 4, 9, 17, 19, 24 to 26; Vol. X., 2, 13, 16, 19, 26; Vol. XI., 18; Vol. XII., 3, 8, and 10.

PRIMARY BATTERIES FOR ELECTRIC LIGHTING.*

BY ISAAC PROBERT.

It has been said that "history repeats itself," and this quotation was never more appropriate than to the subject that will engage our attention this evening.

All of us probably know that it was by a primary battery that the electric light was first produced. So far back as 1802 Sir Humphrey Davy, using a battery consisting of plates of copper and zinc dipping into dilute acid, obtained the electric arc between poles of carbon. In the *Journal of the Royal Institution* for that year, Davy, in describing some experiments on the spark yielded by the newly-invented galvanic battery, uses these words:—"When, instead of the metals, pieces of well-burned charcoal were employed, the spark was still larger, and of a vivid whiteness." He also pictures an apparatus for, as he says, "taking the galvano-electrical spark in fluids and aëriform substances." It consisted of a glass tube open at the top, and having a tubular outlet at the side through which a wire tipped with charcoal was introduced, another wire, also tipped with charcoal, being cemented in a vertical position through the bottom.

In the same year the electric light, sustained by voltaic action, was publicly shown in Paris by the citizen Robertson. Professor Sylvanus P. Thompson, in an interesting communication to *Nature*, has quoted a passage in the *Paris Journal* of March, 1802, from which it appears that the experimenter used a voltaic pile of 120 elements of zinc and silver, to each pole of which he attached a carbon. On bringing the carbons into contact a brilliant spark was obtained of extreme whiteness.

A few years later, Davy, with the large battery of 2,000 cells, which the munificence of some members of the Royal Institution had placed at his disposal, obtained an electric light of a power that has rarely been surpassed, even in our own day.

Thanks to the kind efforts of our chairman, one of Davy's original battery cells is on the table to-night. The complete battery, to use Davy's own words, consisted "of 200 instruments connected together in regular order, each composed of ten double plates arranged in cells of porcelain and containing in each plate 32 square inches. The battery, when the cells were filled with 60 parts of water, mixed with one part of nitric acid, and one part of sulphuric acid, afforded a series of brilliant and impressive effects. When pieces of charcoal about an inch long and one-sixth of an inch in diameter were brought near each other (within the thirtieth or fortieth part of an inch), a bright spark was produced, and more than half the volume of the charcoal became ignited to whiteness, and by withdrawing the points from each other a constant discharge took place through the heated air in a space equal to at least four inches, producing a most brilliant ascending arch of light, broad and conical in form in the middle."

The electrician, Children, constructed a battery of twenty cells, having huge double plates four feet by two, of which the whole surfaces were exposed, in a wooden trough, in cells covered with cement, to the action of diluted acids. It was the grandest combination ever then constructed for exhibiting the effects of extensive surface. To quote Davy's words:—"Points of charcoal ignited by it produced a light so vivid, that even the sunshine, compared with it, appeared feeble."

The light obtained by these experimenters was beautiful in the extreme, and naturally excited the admiration and the hopes of the public, or at least of that educated section of the public to whom the advances of science are not unknown; but it was in no way a practical light. The copper-zinc battery used in the experiments was crude, and quite incapable of sustaining a constant current, the carbon points employed for the arc to play between were mere sticks of wood charcoal, which gave an unsteady light and rapidly consumed, and the beautiful regulators with which we are familiar, for keeping the length of the arc constant, were then quite unknown.

It has just been said that the current obtained by the battery employed in those early experiments was not constant. This want of constancy is due to what is called the polarisation of

* Paper read before the Society of Arts, May 28, 1884.

Digitized by Google

the battery—that is, the deposition of hydrogen gas upon the copper plate. In the working of the battery, the zinc plate is oxidised and transformed into sulphate of zinc by the sulphuric acid in which the plates are immersed. At the same time, hydrogen gas is liberated on the surface of the copper plate, where it collects and forms a layer of appreciable thickness, which offers considerable resistance to the transmission of the electric current. It also gives rise to an electromotive force opposed in direction to that of the copper-zinc couple. The effect of the polarisation of the battery is, then, to considerably reduce the current flowing, and worse than this, any amount of deposited gas varies with time and other circumstances, and the current likewise varies. Such a battery, when used to produce the electric light, furnishes a light of constantly varying intensity, which is extremely painful to use, and possesses other drawbacks also.

It is evident, then, that a battery, to be of any use for practical electric lighting, must be capable of generating a constant current. It should also possess these other qualifications, viz., a high and constant electromotive force and a small and constant internal resistance. It should consume inexpensive materials, and should consume nothing when it is producing no current. It should be capable of being easily cleansed, and of being supplied with fresh materials. It should require no skilled attendance. Unfortunately, no battery hitherto invented possesses all the required qualifications.

So long as constant batteries were unknown, the electric light remained a scientific curiosity, but the invention by Grove, in 1836, of his nitric acid battery gave a fresh impetus to the subject. Of all the points enumerated, the power to furnish a constant current is the most important. As the want of constancy of a battery is due very largely, although not exclusively, to the deposition of hydrogen gas upon the copper plate, inventors naturally turned their attention to the devising of methods of ridding the battery of this objectionable feature. Mr. Alfred Smee was very early in the field; he found that by roughening the copper plate the disengagement of the bubbles of hydrogen from its surface was greatly facilitated. The gas, instead of forming a smooth layer upon the copper, collected upon the rough portions, and was discharged upwards through the liquid in streams.

On further investigating the subject, Smee found that it was not necessary that these roughenings of the surface should have appreciable size. In fact better results were obtained with a multitude of small points, from which the gas could be disengaged as quickly as it was liberated by the electrolytic action of the battery, than with a few points of large size, which, although capable of releasing big bubbles, yet permitted the gas to remain on the plate until the big bubbles had been formed by the aggregation of the tiny particles of gas which first appear. He therefore abandoned the copper plate, roughened mechanically, with which his earlier experiments were performed, in favour of a platinum plate, coated with a deposit of very finely divided platinum, obtained by exposing the plate to the action of solution of chloride of the metal, under the influence of the galvanic current. In our own day, platinised silver is often, through a false idea of economy, substituted for the platinised platinum.

This was a very great advance. The Smee battery was justly esteemed at the time for its great constancy as compared with the batteries previously in use. But its constancy, although great in comparison with that of the other batteries then known, was still very far from perfect.

Smee's method of eliminating the ill effects of the layer of hydrogen was but a method of removal, and the question naturally presented itself to the minds of inventors whether a method of prevention could not be devised. An answer in the affirmative was given by Professor J. F. Daniell, of King's College, who invented a battery which remains to this day unequalled in constancy. You may be interested to hear the description of this first constant battery worthy of the name, in its first form, in the inventor's own words. They are these:—

"A cell of this battery consists of a cylinder of copper three and a-half inches in diameter, which experience has proved to afford the most advantageous distance between the generating (that is the zinc) and conducting (that is the copper) surfaces, but which may vary in height according to the power which it is wished to obtain. A membranous tube, formed of the gullet of an ox, is hung in the centre by a collar and circular copper plate, resting upon a rim placed near the top of the cylinder, and in this is suspended, by a wooden cross bar, a cylindrical rod of amalgamated zinc, half an inch in diameter. The cell is charged with a mixture of eight parts of water and one of oil of vitriol, which has been saturated with sulphate of copper; and portions of the solid salt are placed upon the upper copper plate, which is perforated like a colander, for the purpose of keeping the solution always in a state of saturation. The internal tube is filled with the same acid mixture without the copper. A tube of porous earthenware may be substituted for the membrane with some little loss of power. A number of such cells admit of being connected together very readily into a compound circuit, and will sustain a perfectly equal and steady current for many hours together, with a power far beyond that which can be produced by any other arrangement of a similar quantity of the same metals.

"The surface of the conducting metal is thus perpetually renewed by the deposition of pure copper, and the counteraction of zinc or any other precipitated metal effectually prevented. The minor affinity of the copper for the acid, however, still remains, and such an opposition could only be effectually avoided by the employment of platinum plates, perpetually renewed by the decomposition in the circuit of chloride of platinum; such an arrangement would be perfect, but too costly for ordinary applications."

This battery, the prototype of all chemical depolarising batteries, is worthy of attentive study. In it the hydrogen, instead of being deposited upon the copper plate, is oxidised to water by the solution of copper sulphate, and metallic copper in place of hydrogen is thrown down upon the copper plate. Polarisation is thus entirely prevented.

If constancy of current were the sole requisite of a battery for electric lighting, the Daniell battery would be admirably suited to the purpose, but it will be remembered that a high electromotive force and a low internal resistance are also essential, and here the Daniell battery fails. The electromotive force of any copper zinc couple is low, and the internal resistance of the Daniell cell is high. The electromotive force might be raised by the device suggested by Daniell of employing platinum in place of copper, and solution of chloride of platinum in place of solution of sulphate of copper, but the expense would militate against the practical success of such an arrangement.

It was reserved for Grove—now the Hon. Sir W. R. Grove, one of her Majesty's judges, but then Professor of Chemistry at the London Institution—to overcome this difficulty, and to produce a chemical depolarising battery of high electromotive force, low internal resistance, and employing a comparatively cheap depolarising liquid. Daniell, as we have seen, had appreciated very clearly the advantage of a platinum plate, but his mind seemed so engrossed with his original idea of a metallic solution, as depolariser, which in decomposition deposits upon the plate dipping into it a layer of the same metal, that the possibility of finding a non-metallic depolariser does not appear to have suggested itself to him. Grove, however, saw this possibility, and by the substitution of strong nitric acid for the metallic solution achieved the success which Daniell had vainly sought for. For the first time the production of the electric light by the aid of a primary battery became possible on a practical scale; and the very year of Grove's invention the electric light was used for theatrical purposes at the Opera House in Paris.

Suggestions by Cooper, Walker, Bunsen, and Archereau quickly followed, and in the course of a few years the nitric acid battery had assumed its present convenient form.

It would be tedious to tell you of the many attempts to practically introduce the electric light which now rapidly succeeded one another. One of the most noteworthy instances of the employment of this battery is the electric lighting of the Cherbourg Docks, during their construction in 1858, whereby 1,800 men were enabled to work during the night, when work must otherwise have been suspended.

Digitized by Google

In 1831 Faraday made the important discovery that when a closed circuit of conducting material—a ring of copper, for example—is moved in the neighbourhood of a magnet, so that the conductor passes from a position of one magnetic intensity to a position of a different magnetic intensity, a current of electricity is generated in the conductor, and that when the conductor is moved, so that a current is generated in it, more mechanical work is done in producing the motion than when no current is generated. In effect, this great discovery was that by the intervention of a magnet and a coil of wire, mechanical energy—the energy of the arm or of the steam engine—can be transformed into electric energy. Out of this discovery have grown the huge dynamo-electric machines of to-day, which, as generators of electricity for lighting purposes, have almost driven voltaic batteries from the field of competition.

Why is this? Why is it that a dynamo-electric machine should be almost universally preferred to a voltaic battery for the production of the electric light? It is a question of cost—of the relative cost of the two methods of producing an electric current.

(TO BE CONTINUED.)

TELEGRAPH TARIFFS.*

BY COLONEL WEBBER, C.B., R.E.

[In accordance with the promise contained in the leading article in our issue of May 31, wherein we criticised Colonel Webber's proposals as stated in the following paper, we reprint this paper, despite the fact that it was read more than a month ago.—Ed. *E.*]

The subject which your council has requested me to bring before you this evening is one that would require far longer than the limited time at our disposal to permit of its being exhaustively dealt with in all its branches.

As the introduction of the sixpenny rate in our own telegraph service has been so long under discussion, in and out of Parliament, and as a resolution "that the time had arrived for a reduction" was adopted by the House of Commons in March, 1883, and as the Chancellor of the Exchequer has, since that date, been carefully considering the conditions under which the reduction to a sixpenny uniform rate can be brought into force, it is hoped that the public ventilation of the subject within these walls may have the effect of establishing a cheaper rate, in one form or another, at an *earlier date* than is anticipated by the latest official announcements on the subject.

I am in great hopes that officers of the Post Office now present will find themselves in a position to discuss, criticise, or overthrow in fair argument, if they can do so, the propositions which I, as an old brother officer who hopes he has kept up his knowledge of telegraphy and its traffic, am able to lay before you.

In the public interest I shall urge on all who may wish to speak to endeavour to confine their remarks to the very narrow issue which you will find in the outcome of this paper.

To assist the audience in dwelling on the subject, tables are given with some foreign inland rates, and the corresponding value in English money for thirty-two words. Practically our rate of one shilling includes an average of twelve words in the addresses. By the following comparison, the figures of which are only approximate, it will be seen that, with the exception of Belgium, Holland, Switzerland, and Italy, we get most for our money, when it is considered that our free delivery is for one mile, and theirs for one kilometre.

Inland Tariffs.

Account of the Nature of the Service Rendered by the Post Office in the Transmission of a Telegram.—The machinery of transmission may be classed as follows:—The offices; the *personnel;* the mechanical means; the electrical means; the porterage. The public does not probably realise the extent or nature of these means, nor the organisation that is necessary to set them in motion, to keep them at work, to provide supervision, and to utilise these means profitably.

The Office.—Each telegram must pass through two, the forwarding office and the receiving office; often through more than two, having, more frequently, to be *transmitted* at one or more intermediate offices. The forwarding office requires a counter where the sender writes his message, another where the clerk receives, passes, and prepares it, and a third where the telegraph clerk signals it to the next station on its route. For this operation the white paper Form A is used, and this, the original message, remains the property of the Postmaster-General. The tariff of this message, as is well known, includes free addresses, one shilling being paid for 20 words; but as this rate increases for every additional five words, the principle is that of a word rate; in fact, it is altogether an empirical tariff. The *postal* feature of it is, that encouragement is given to full addresses. The counter clerk is not saved the labour of counting the words if the message is not written clearly in the spaces provided on the form, or if the four lines are nearly or quite filled. Passing 21 words by accident for 20, and charging 1s. instead of 1s. 3d., would be visited on a clerk by the punishment of fining. If the sender's message is for a place beyond the United Kingdom, the counter clerk must also understand how to charge and deal with it.

The Instrument and its Clerk.—The instrument clerk, or the operator. His knowledge must not only include what may be called the language of telegraphy—meaning the various classifying code signals, which must be sent as well as the message itself—but also the actual art of signalling with the Morse code. Omitting reference to the use of telephones or alphabetical instruments for signalling purposes, I will only draw your attention to this art, in which the young alone can become really efficient. Few realise its difficulty, and the fact that no one can become a thorough Morse clerk without years of practice. I do not refer to those who are just efficient enough to spell out the words slowly, either in sending

* Paper read before the Society of Arts, May 21, 1884.

Digitized by Google

or receiving, or who, even when quick at sending, must resort to the use of the printed Morse slip of paper to read, and whose ears have not acquired the wonderful power of reading groups of signals as words, but to those to whom the whole operation of sending and receiving has become a language of the hand and ear.

The Mechanism.—Part of the mechanical means by which the message reaches its destination sometimes consists of a pneumatic tube from the counter to the instrument room, occasionally worked by a bellows. The well-known mechanism of the Morse printing key, by which the long and short electrical impulses are communicated to the conductor, the source of energy in the battery, and the insulated conductor starting from the instrument, at first covered with gutta percha, then crossing house-tops, roads, fields, and rivers, insulated by the air throughout its length, except where carried on insulators at the points of support, and so away to the distant station containing the receiving instrument, are too well known to need description. It is sufficient to give an idea of the value of such a line of communication 100 miles long to say that if the poles conveying it carry several wires besides, the cost of such a plant is, roughly, not less than £1,300.

The Intermediate and Terminal Offices.—But if the message has not completed its journey on reaching the station at the first 100 miles, the receiving clerk, who has been warned by a special prefix, selects a yellow coloured form (B) in place of a red one, and the message, when taken down, is passed to the clerk working the instrument on the line reaching to the office of destination. Again, similar means, physical, mechanical, and electrical, are brought into use, very slightly varying in operation according to distance, and the message eventually reaches its terminus, to be taken down on a red coloured or C Form, and duplicated by means of a second sheet with carbon paper between. The original is kept, and the manifold copy sent to the counter clerk in the public office, who, having recorded it, places it in an envelope, addresses it, marks outside the time of despatch, the charge of porterage beyond one mile, and despatches it by a telegraph messenger boy in waiting. The Post Office, it will be seen, preserves at least two, most frequently three, copies of each message that is carried. These copies are eventually brought together and checked in a clearing-house.

Approximate Cost.—The annual cost of the route for the transmission of the message described above may be very roughly computed as follows, excluding the value of administration, which it would be difficult for any one outside the Post Office to assess. Let us adopt, as an example, the case of three offices, containing on an average (what would give) five instruments per office; and a route not passing through a first-class central station, the conditions of which are more complicated. Let us also use the simple example of a wire carried on a road line of telegraph, not on a railway line, where the Post Office pays exceptionally high rates for way leave and maintenance.

It works out as follows:—Share of three offices at £20, £60; share of two counter clerks at salaries of £70, £30; three instrument clerks at £50, £150; one boy (less receipts for delivery beyond one mile), £14; share of office superintendence, £30. Cost of plant: Three instruments and batteries, £60; 200 miles of line, £2,600—£2,660. Interest and depreciation at 7 per cent., £186; maintenance of road line at 12s. a mile, £120; supervision and sundries, £30—total, £680.

This total, after striking off a few for Sundays, represents an average of forty-three shilling messages a day. At a low rate of speed this work would occupy two hours a day. Probably in practice it would be spread over three or four hours. Thus, taking this example as a mere indication for the guidance of my audience, there remains twenty-one hours out of the twenty-four for this route to earn a profit. As the conditions of no two routes are precisely similar, and as some vary widely from that which has been given you, there is no desire to quote these figures as the basis of any but the most general conclusions. The object in laying this example before you is to give as simply as possible a general idea of the nature and value of the service rendered.

The Distance Rate.—At the earliest establishment of the electric telegraph, every one connected with it seems to have thought of no other classification of rates except that governed by distance. This was rational enough, as the administration of those early lines was largely in the hands of people who were connected with railway traffic, who at once turned their attention to making each communication pay for itself. While there were comparatively few messages, and any speed greater than that of a railway train was worth paying for, no better mode of charging could be suggested. All the means were expensive, the manipulation, the instruments, and the line, and no acceleration was attempted which increased their cost; hence distance rates commended themselves at once. With three great companies competing before 1870, the mode of charging by distance lent itself effectively to competition. The United Kingdom Company, which started with a uniform shilling rate, was nearly stifled, and had to adopt the distance rate.

Sir James Anderson on the Effect of Reduced Tariffs on Telegraphy.—In 1872, this well-known telegraph manager published a pamphlet on telegraph tariffs. At the time he wrote (1872) it was still under discussion if private undertakings could afford to reduce rates, although the results in Switzerland, Belgium, and the United Kingdom gave ample proof that judicious reduction gives splendid results. His conclusion was that the highest return upon the capital invested is obtained from a high tariff, and that competition would always check the extension of unproductive facilities to the public. Hence he believed that a monopoly was essential to the creation of a system which would be self-supporting, for the benefit of the public. We know that Mr. Scudamore never shared that belief with the Government of the day which obtained it from the House of Commons, and we know how that monopoly acted fatally in checking the reduction of tariff in this country (long since overdue) by inflating the capital account of the business. Sir James Anderson goes carefully into the reports from Belgium, and shows how the conditions of the *international* differ from those of the *internal* traffic. He eliminates from actual returns the abnormal stimulus of increased facilities, and discovers a normal rate of progression in the fourteen years with which he deals of 12½ per cent., which being independent of increased plant is a measure of the clear natural increment. He then obtains a comparison between the rate of progression of expenses and that of the abnormal augmentation of correspondence. With each of these figures he endeavours to show the large amount of profit sacrificed by lowering the tariff. His contention that the results of the working of *international* service in Belgium, on which reductions of tariff to the same extent did not take place, at first covered a deficit on the *internal* traffic, seems to be proved, and makes us cautious in accepting the Belgium figures of those days in their entirety. There is one point which I wish you to consider, which is that Sir James's personal experience was more built on the service of great arterial communications than on a network system. From this point of view, a word rate, subject to distance, would be most rational. Cables have a different capacity. If there is but one communication, nothing can prevent delay on messages. For example, if the offices at both ends are clear of message work at 9 a.m., and messages at the rate of twenty an hour be handed in by the public up to 12 o'clock, and the cable can only carry ten an hour, it is plain that the message handed in just before noon cannot be sent on till 3 o'clock, bearing with it three hours' delay in comparison with the message handed in at 9 a.m. Acceleration, therefore, in the first instance, would have little effect on the calculations of a tariff for such a line. Competition, as between the United Kingdom and America, immediately gives rise to the obligation to accelerate by duplication of the cable. The rate founded on distance, or in other words, on outlay, then becomes subordinate to time, and the application of that coefficient becomes a source of expense, showing that acceleration raises working cost. The converse of this receives illustration in the *Proceedings* of the Select Committee of the House of Commons in 1868 on the Electric Telegraphs Bill.

In the Appendix to the Report, No. I., page 8, there is a quotation of the view then held in Belgium by the Director of Telegraphs. He points out "that in fixing lower rates the Government by no means assured the same facilities to the public." They were told that—"They must not consider the half-franc telegrams would assure them either speed or accuracy. The message at the reduced rate should be considered as one that would be conveyed at about the speed of a railway train. If the public require acceleration they must rely on the half-franc message. For extra speed, or preference, or an 'express message,' two higher rates must be used." No really important sacrifice of speed was contemplated, for in the same report he claims for Belgium, then, a higher mean speed than in any other country; in fact, he made the ordinary message third class, and accelerated messages, for which more was paid, as second and first class messages.

The Telegraph Circuit, and its Working Conditions.—The term circuit, as many of those present know, is a telegraphic expression, intended to describe the popularly understood path between the terminal offices of the electric current in the one direction by the wire, in the other or return direction through the earth. A completely equipped circuit must include the operators. The conditions under which a telegraphic circuit is worked vary considerably in one country, and between countries. Some of those conditions may be described briefly, for instance, as regards the services of operators. They may be highly skilled male clerks, able to work at high speed for many hours at a stretch, possessing great readiness of resource; equally skilled female clerks, but with less physical capacity for endurance, and less resource in difficulties; clerks who in addition understand the simple maintenance of the instruments and batteries; others who require more or less the assistance of skilled maintenance men; clerks who are mere learners, or who have only experience acquired on needle instruments; others in country post offices, who are members of the postmaster's family, and occasionally his aged wife or youthful

Digitized by Google

grandchild. In the United Kingdom there is a considerable variety of instruments in use, partly due to the original acquisition by the Post Office of the plant of various companies, and partly to the varying powers of the operators that have been mentioned. I am indebted to my friend Mr. Preece for an approximate list of the number of instruments of each kind in use in the postal telegraphs, exclusive of telephones :—Wheatstone A B C instruments, 4,183 ; needle instruments, 3,883 ; Morse recording instruments, 1,107 ; Morse sounder instruments, 1,712 ; Morse recording instrument, worked duplex, 283 ; Morse sounder instrument, worked duplex, 357 ; quadruplex, worked with sounders, 27 ; Wheatstone automatic, 173 ; Wheatstone automatic, worked duplex, 64.

Besides, there are conditions of speed of minor importance to the subject before us, and also conditions of maintenance of the lines due to weather, which are certainly different in a mild and moist, to those in a rigorous or dry climate. Lastly, there are conditions of supervision and superintendence, which are most evident to those who have been engaged in the operations of the service. It may be said that, in common with kindred operations, efficiency of service and remunerative results largely depend on these. A telegraph system such as ours is a huge machine, working day and night, stretching over a vast area, dependent on varying local circumstances, and yet subject to one general code of laws, rigid and yet elastic in their imposition. With nothing else that I know of can it be so well compared as the nervous system as described by Herbert Spencer. It is the most perfect example of centralisation, tempered by decentralisation, the balance between them being preserved exactly as the administrators are guided by the indications of demand and supply. And the more I have studied the subject the more it has struck me that only where the administrators have strained the application of natural laws there only has the service failed to extract the maximum of possible result. The superintendents of this beautiful machine must have an intimate acquaintance not only with the best possible work obtainable from the means used, both human and material, but also with the thousand militating occurrences to which every part of it is liable ; so that, while always striving for excellence, too much shall not be demanded, and waste arise in the opposite direction. That this supervision has been well guided experience proves. And I will endeavour to show you that the success of the ultimate objects for which it is contending, namely, producing efficiency of service for the public, must all turn on the proper understanding and use of one coefficient, namely, *time*; that the measure of cost and of accuracy must be subordinate to the expenditure of *time*. Those who have been engaged in this supervision, and who have had to investigate complaints about accuracy or delay, will be the first to acknowledge that the ultimate conclusion of their research had been chiefly governed by the condition of *time*; if any improvement in the future is to be reaped, it will be through tracing the fault, whether physical, mechanical, or electrical, home to its true cause.

The Capacity of a Circuit.—Like other machines, a telegraph circuit has a measurable capacity for work. As in the case of a line of railway, it can carry traffic continuously, subject to working conditions of speed and safety, service and maintenance. Railway managers could give you many examples of lines worked fully up to their maximum capacity, even verging on the insecure, and they would add that out of the needs of the public have arisen classifications of traffic, namely, into various speeds, that some lines have to be devoted entirely to high speed, other to slow speed traffic, and that from some lines the maximum result of capacity is obtained by working both, confining each to different periods of the 24 hours. We can all understand that in few cases will practice attain the theoretical capacity of a line worked with trains following one another, travelling at equal speeds, and with safe intervals, and equally we can understand that the best commercial result will be obtained by the manager who best adopts and dovetails all the means at his disposal to meet the demands of his customers. Again, we can all clearly appreciate that traffic itself is subject to classification in its varieties. Thus, with passenger traffic, it can be subdivided according as persons are ready, from various motives, to pay for various rates of speed. Similarly with the carriage of live animals and perishable and imperishable goods. But while the powers of the railway manager to meet these demands in equal variety are limited, it is undoubtedly the case that the first object is to do so, especially when under the pressure of competition.

Telegraph Traffic Commercially Worked.—Now, to a much smaller degree, telegraphic traffic is subject to the same influences, if its management is truly commercial in its instincts. In using the word "commercial," I ask my audience to admit that in whatever way we regard the service of the public by a department of the State, the word "commercial" equally applies whether the system is worked at a loss, or without loss, or at a profit. Whatever the result, "commercial" working will mean working on a basis ; first, of extending facilities to every point to which private undertakings would extend it under the influence of competition ; second, of working on sound economical principles. It is true that when the State first took over the telegraph companies' business, many of the early extensions were very uncommercial ; but this was a weakness from the effects of which fifteen years' working has long ago recovered, and which for many years has been counteracted by the exactions from localities of guarantees to cover at least working expenses before extensions are permitted. If true commercial instinct is to be exercised in the management of our telegraphy, it would appear that, somewhat in the way I am attempting to describe, every circuit should be used in such a way as to obtain from its use the maximum gross revenue. As for all other kinds of means of transport there is a market ; the commercial instinct seeks the market and develops it, which means organising a system which will extract from it all that can be gained. Thus Pickford, Chaplin and Horne, in England, and Bianconi in Ireland, created a business ; if the demand had not been latent, they could not have made it pay. A department of the State serving the public, if the object is not to pay, should obtain still better results. If it is seeking to bring revenue into the Exchequer, it ought to produce quite as good results, with several advantages which no private undertaking can have.

Development of the Postal Telegraphs.—Let us inquire for a moment how far the Post Office has developed the latent telegraph as business in the country. They carry, say, 26,000,000 of telegrams, as against 8,000,000 before 1870 carried by the companies. This marvellous result has been obtained working on almost precisely the same main lines as when the Government first took the telegraphs in hand. Those broad lines have been a maximum of speed at a nominally uniform charge ; and, without considering the lessening of speed due to the means which, for economy of working, have been adopted in circuits of least importance, doubtless the highest results possible under those conditions have been obtained. The question then remains—Has the rigid adherence of these main lines of procedure obscured their vision, and prevented their discovering outlying regions of profit waiting to be reaped, greatly to the advantage of the public, and to the increase of revenue on the lowering of rates ? Ought we, out of pure gratitude for what has been done, to shut our eyes to this inquiry, and decline to allow that the Post Office may err, or have its vision narrowed within the range of the great reservoir of custom, which it has not only tapped exhaustively, but also developed in size ? The Society of Arts, years ago in the van of the movement which led to the acquisition of the telegraphs by the State, and always ready to place its arena at the disposal of the public for discussion, ensures, by its countenance of such an investigation as this, that it will be treated in the fairest spirit, and that every question or objection shall have the most serious consideration.

Possible and Actual Capacity of Existing Circuits.—Let us look at the possible capacity of the instruments of which I have already given a list :—

	Messages per annum.
A Wheatstone A B C instrument has an hourly capacity for 34 word messages of 15, or in 12 hours of 180. This, for 2,092 instruments for 310 days, gives a total of	116,705,700
A needle instrument has an hourly capacity for 25 messages of 34 words each, or in 12 hours of 300 messages. This, for 1,942 instruments in use, gives for 310 days	180,559,500
	297,265,200

The figures are so enormous, and representative of nothing within the range of probability, that it is is only necessary to mention the gross receipts at a shilling a message would amount to £14,863,260. In actual practice these instruments, at a very low estimate, probably forward on an average—every 2 A B C instruments, 6 messages a day ; every 2 needle instruments, 10 messages a day.

	Per anum.
Representing—A B C....................	3,891,120
Needle	6,018,200
Total	9,909,320

Which, at one shilling, amounts to £495,466, or 1-29th of the possible capacity. The same calculation applied to the Morse recorders and sounders, allowing them a message of 34 words capacity of 30 and 35 respectively, gives a possible capacity representing £8,663,880 ; and this in actual practice, allowing 20 messages a day for recorders, and 25 for sounders, amounts to £513,440, or 1-17th of the possible capacity. These figures, however approximate in their accuracy, are sufficiently based on fact to convince you that there is a very large margin of time during each day when circuits are idle, and when the mechanical and electrical machinery is at a standstill.

Digitized by Google

Utilisation of Spare Capacity.—The question immediately arises how to utilise a portion of it. I have only dealt with twelve out of the twenty-four hours. The Post Office already utilises a proportion of the remainder of the twenty-four hours on many circuits by working them for press messages, at rates so unremunerative that it is doubtful if they pay for the actual manipulation. I have only dealt with twelve hours of the twenty-four, because all offices are already open during that time, and in offices with one instrument only a manipulator is always present. This manipulator, I have assumed, now deals with 6, 10, 20, or 25 messages a day, according to the class of office and instrument. If he worked away steadily for eight of the twelve hours he would deal with 120, 200, 240 and 280 messages. It is not straining this demand on his or her powers to expect that half those numbers could be dealt with without increasing the labour staff. Again, in offices with two or more instruments, periods occur daily when neither instruments nor clerks are fully occupied. The larger the offices, the fewer or less frequent are these periods, for the following reason :—Although an office may open at 7 a.m. and not close till 9 p.m., the time during which all the instruments are at work is probably limited to between 11 a.m. and 3 p.m., then all the clerks are hard at work. For about two hours before and after those hours but half the clerks need be present; probably early and late only one or two are wanted. Thus, by judicious dovetailing of the hours of work of each operator, the full time of each is fairly occupied throughout most of his working hours. In the largest offices this can be carried out with great perfection, but in the vast majority of medium-size offices there exists a margin of available labour which can only be adjusted by having too small an establishment of clerks. Its effect is a certain delay in every message during the busiest hours, and the accomplishment of work during times of slight abnormal pressure of business, by allowing the operators to work *overtime.*

High Standard of Time Aimed at in Postal Telegraphs.—Fortunately for the public, and the well-earned and maintained credit for speed won by our postal telegraphs, the department has always aimed at accomplishing what is highly creditable, and unequalled in most other countries, namely, that a message is considered to be delayed when the time taken to deal with it in any one office exceeds ten minutes. Now, this is a very high standard to aim at, and it can only be maintained, in all but the largest offices, by a redundancy of the manipulating staff, so that the very effort to serve the public will, in the matter of time, necessarily result in a margin of unutilised labour, as well as of mechanical and electrical means. I know that postmasters exercise great judgment in applying spare telegraphic labour to postal work, and *vice versâ*, but there must still remain hours during which some labour is still available to work the machinery lying idle under its hand. But where are the messages which will require transmission? My answer is, they will be forthcoming by a lowering of rates, when accepted on the understanding that they are to be sent during those periods that the machinery is now idle. The history of all telegraphs places it beyond discussion that every lowering of rates of any kind produces increased traffic of one kind or another. If the increase proves to be greater than can be dealt with by the margin of labour I claim to exist, then additional labour and working expenses at cost price must be added. I believe that 1½d. per message in each office which deals with it will amply suffice. If the demand exists for cheap telegraphy under conditions of speed less than those now aimed at by the Post Office, why not supply it? Why give the public a uniform speed on all messages? Is it not rational to suppose that there are messages which will fulfil their purpose equally well in the mind of the sender if delivered in three or four hours after being handed in? Does it not at once appear evident that the elimination of every fresh message, now sent in its code turn with the most pressing messages, will add to the punctuality of the latter? Whether we call the first messages express, or the slow-speed messages deferred, does not matter. Does not a classification of this kind coincide with the fundamental law of the government by time of all the conditions of telegraphic supply and demand? If we analyse the means used in telegraphy for increasing speed, we find that it is entirely a question of cost.

Cause of Delay.—If a message is handed in at an office between 11 and 11:5 with six others, including counter work, the first of the seven is completed in, say, three minutes, the next in three minutes more, and so on, the seventh message will have accumulated over sixteen minutes delay on reaching the transmitting stations. Here other delays may occur, and while the first is got through within ten or twelve minutes, the fifth is not ready for delivery for more than half an hour after receipt. All delays of such a kind can be lessened by increasing means, duplexing wires, doubling the operators, and so on. The greatest speed of a Wheatstone automatic circuit is achieved by costly apparatus and unlimited labour at each end of the wire. Increasing the wire accommodation may have to be resorted to to keep down delay when all other means fail. Is it not a much simpler experiment, to save expenditure and maintain speed, to offer the public inducements, by cheaper rates for less speed, to select of its own accord the slower route, when first-class speed is not essential? If the only gain were to reduce the work during the busiest hours of the day, and confine it to the supply of the demand for higher speed, the result would justify the change. When it also means the occupation of circuits, where otherwise they would be comparatively idle, by work eminently not suffering from such delay, through the selection of the customers, there would appear to be a large balance of evidence in its favour. But if, also, the cheaper rate taps a reserve of message-sending not now sounded, and if the increase of traffic of this character largely exceeds the loss on the messages for which the cheaper means have been selected by customers in preference to the old rate, surely this increased efficiency of the fast service, and the added facility to the public of the slower service, would alone more than prove the soundness of such a measure.

Dr. Playfair's Committee.—I will now refer my hearers to a paper laid by me in evidence before Sir Lyon Playfair's Committee of the House of Commons, in 1876, suggestive of a scheme of "deferred" or "second-class" messages, and descriptive of the means by which I proposed to bring it into force. This had been the result of several years of constant observance of the daily working of the system in the district of which I was the divisional engineer, and of careful inquiry amongst all the persons in that district upon whom would fall the labour of bringing it into force. I was not met by one dissentient as to the practicability of the proposal. If I ever encountered objections, they were derived from the experience of the great central stations, where slackness of work is never apparent. I claimed, in 1876, no novelty for the proposal except that its essential feature was its perfect adaptability to the postal telegraph system. It claimed to tap a new source of revenue without materially diverting existing channels, and to utilise existing spare means with little change. It designs to leave the 1s. message alone with its existing conditions and facilities, and that the Post Office should accept a new kind of *petite vitesse* message, and forward it under certain conditions for 6d. This message, if thought well, might be called "second-class" or "deferred," the main condition of transmission of the messages to be, that no second-class is forwarded while a first-class message is on hand. The effect of this would be :—1. That the 1s. message would remain as it is (subject to alterations as to payment of sender's address). 2. In practice, the second-class messages would only experience serious delay in busy offices, on busy lines, during busy hours. 3. Local telegraphing in country districts and towns would be developed; and circuits now only occupied with a dozen messages a day at 1s. would probably lose half these, but carry 20 or 30 at 6d. when it was found that on local traffic no real delay occurred by using the lower class. 4. It was suggested that this class of message should include only ten words, and that free delivery should be only for half a mile, and the second half mile be charged 3d.; but there is no reason why the delivery should not remain as it is for 1s. messages. 5. It was foreseen that the public might at first adopt more largely the use of second-class messages than the revenue could bear, and it was pointed out that as soon as those who did so found their messages suffer in speed they would revert to the shilling rate, with the greater satisfaction of obtaining a somewhat accelerated service for their money. The working was provided for by distinguishing second-class messages by forms of a different tint, or by strongly marked bands, or by large figures.

TABLE A.

First Class.				Second Class.			
Estimated words in address.	Words in message.	Total.	Charge	Estimated words in address.	Words in message.	Total.	Charge
			s. d.				s. d.
12	20	32	1 0	12	10	22	0 6
12	25	37	1 3	12	20	32	0 9
12	30	42	1 6	12	30	42	1 0
12	35	47	1 9	12	40	52	1 3
12	40	52	2 0	12	50	62	1 6
12	45	57	2 3	—	—	—	—
12	50	62	2 6	—	—	—	—

At the instrument it was proposed that second-class messages should be placed at the bottom of those lying before the operator, below the first-class ones, and as long as any of the latter were waiting to be sent to allow the former to accumulate. But immediately a clerk had "got off" all his first-class he was to go on with the second-class till a fresh first-class reached him.

A table is exhibited (Table A) showing the number of words that would be transmitted under the two rates. It will be seen, assuming

Digitized by Google

that a wire carries on an average 20 words a minute, it could earn 6d. a minute at the second rate.

The report of the House of Commons Committee referred to this in the following terms :—"The essence of this plan is that in small localities telegrams would be largely multiplied, and that wires which now remain comparatively idle for a considerable portion of the day would have fuller and more evenly distributed work. This proposal has the merit of not disturbing the ordinary 1s. messages, and offers cheaper rates for such as can be delayed with a minimum dislocation of the present system. There is no greater disturbance of uniformity in this plan than in the various changes of the postal system, in which higher rates are charged for greater facilities."

The Postmaster-General's Opinion on Deferred Messages.—On 23rd July, 1880, Mr. Fawcett expressed himself adverse to the proposal when replying to a deputation of this society in the following terms, thus :—"There has been another suggestion made which I think it well to refer to, as I believe it has been discussed in public, that you should have two rates of charge ; what are known as 'deferred' telegrams charged at cheaper rates. For instance, those persons who go to the City telegraph office and pay 1s. for a telegram should have it sent off at once ; those persons paying sixpence should have their telegrams sent off when all the shilling telegrams have been got rid of. So far as I am concerned, I never could sanction such a scheme as that. It seems to me to have this fatal blemish that it would always impress the public with a sense of unfairness, and every person who did not get his telegram sent off, or receive it so quickly as he expected, would think the delay was owing to a preference given to a more influential or wealthy sender. It seems to me a principle of cardinal importance to maintain that there should be no distinction of persons—no distinctions with regard to preference—but that, as regards the first person who goes into a telegraph office, that the office should send his message first. If any departure is made from this principle, I am afraid that all confidence in the fairness of the telegraph service would be removed."

It is with the greatest deference to his wisdom and position that I venture to ask the meeting to consider for one moment the Postmaster-General's objections to establishing two classes of speed, for two rates of payment, for the carriage of telegrams. How far his reply was satisfactory to the deputation from this society I cannot say, but you will not be surprised if I ask you all not to feel in any way satisfied with it. The Postmaster-General recognises none of the financial and commercial advantages of the plan ; he offers no objections to it on account of any difficulty in working ; he simply adopts what I may call an eminently postal view of it. When I call it by that name, I mean that it is one of the oldest forms of answer employed by the Post Office when pressed from the outside to make any changes not originating within its own walls, namely, to say that the public would not like any change. This well-known objection has been in its time used against the Post Office Savings Bank, Insurance, and Parcels Post, prior to the birth of each, and their greatest opponents dwelt within the walls of St. Martin's-le-Grand. However, like all sound schemes, after an interval in each case, the wisdom which predominates within that world-famed establishment weighed down the scale, and the boon was granted. I must say that I am too great a believer in the soundness of Mr. Fawcett's own teaching to believe that he really thinks the public will object to two kinds of telegrams, more than they object to two classes of railway carriages or trains. They do not object to the different speeds in book and parcel post. They are quite able to understand paying differently for different speeds, and when the payment and selection is in their own hands, where is the reasonable suspicion of preference or unfairness? Uniform rates possess a fascination for some people, but what has become of the uniform rates within the Post Office itself? Is not its uniformity subject to the coefficient of weight for letters, and number of words for telegrams? Why not try the time rate? It is true the British public has been educated by the postal telegraph system, on unsound principles, to know nothing about the costliness of speed in respect of telegrams, and they mostly believe that the value of the service rendered is measurable by the number of words. But is it ever too late to restore the British mind to a healthy state on any subject? In Belgium the value of acceleration in the transmission of letters is recognised as having a distinct value, and facilities are given by which letters can be sent from place to place in less time than is occupied by the ordinary post. By writing the word "express" conspicuously on the envelope, and attaching an additional stamp of the value of 25 centimes to a letter bearing a 10 centime stamp, the sender secures preference for his letter over others, and it is sent to its destination by the quickest means. For instance, an "express" letter is sent by the next train leaving the place of collection by the Post Office, and is delivered at the other end of its journey by a special messenger. We do not hear that the Belgians look upon this as conducive to unfairness, or as giving the rich a preference over the poor man. One word more about the uniformity of rate question. There is a good deal about it in the *Proceedings* of the House of Commons Committee, on the Electric Bill of 1868 ; and it is frequently alluded to in the examinations of the late Mr. Scudamore ; also of Messrs. Harrison and Patterson, and of Professor Jevons. I am led to think, by a careful perusal of their evidence, that the uniformity they were advocating was as against what they called the irregularity and even "injustice" of the old companies ; and that the uniformity to which there has since been a tendency to wed us is an exaggeration and distortion of their views. Mr. Scudamore speaks of the advantage of uniformity of rate as "permitting the use of stamps," and as "simplifying telegraphy." He evidently alludes to the complications of the existing distance tariff, for later on he approves of the twenty word message at 1s. and to the fifteen word message at 6d., with a 1d. added five words additional. Again, uniformity was advocated by several witnesses as a necessary consequence on obtaining from Parliament a monopoly for the Post Office ; but Professor W. S. Jevons considered that the "sounder" principle was to arrange rates so that each communication should more or less pay for itself, and he expressly stated that he did not advocate a monopoly, and would rather rearrange rates than protect the system in that way. All the witnesses referred to the success of the uniform rate for postage, and examples were given how, in some cases, the actual cost of the transport of letters to the Post Office was 2d. and 3d., in others only ½d., as a justification for doing away with the distance tariff, then in existence, of 1s. for 100 miles, 1s. 6d. 200 miles, and so on. Looking back on these records, it looks as if the dislike to the existing tariffs, more than a real similarity between telegraph and postal work, weighed most with the advocates of a uniform word-rate under all conditions (amongst whom Mr. Goschen was prominent). Lastly, all the witnesses who spoke on the subject had then had no practical experience of the working of telegraphs. The difficulties which influenced their minds have long since disappeared, and exceptional alterations in tariff have been introduced into the postal telegraph service without observation. The caution which is slow in adopting alterations as improvements cannot be too much admired ; but it is well-known that the backwardness of public departments in this respect is more due to the inertia which "rests and is thankful," to the instinct of heavily worked officials to retard the introduction of thankless reforms, and to the deadening effect of official routine, which nips in the bud the energy of most of the men who, in other walks, would be in the van of advancement.

The Indian Telegraph Department.—Although administered under several essentially different conditions, its working and procedure as regards tariffs will interest the audience. One or two great differences are worth bearing in mind. The telegraph in India is essentially a European service, and English is used ; it cannot yet be said to be in use by the millions of our fellow subjects in that country. It is much used by the State and by local governments, the numbers in 1882-3 of State messages to private having been as 247,000 to 1,103,688. The distances in India being very great, a telegram often takes the place of a letter. As regards a very large proportion of the traffic, time is of less importance than here, distance is a more influential condition. Founded on the experience of a far longer period of State control than this country has enjoyed, we find the Government of India expressing itself in November, 1881, as "willing and anxious to forward any scheme for developing and facilitating communication by telegraph, so far as this can be done without risk to the interest of the general tax-paying community ; but in the interest of that community it is essential that the telegraph service should be self-supporting." In pursuance of this object, we find that the Government approved on that date of a scheme for the "revision of the tariff, which, affording room for a very considerable future reduction in rates, will admit of a large expansion of the traffic without necessitating additional expenditure on increasing the number of the wires. The main feature of this scheme consists in the introduction of arrangements which will permit of the disposal of message traffic in order of urgency, instead of, as at present, in order of presentation of messages. The minute in Council recognises that in the case of commercial and State telegrams almost the whole are tendered for transmission during the business hours of the day, the result being a great pressure of work for a few hours, while for the rest of the day and night the wires are comparatively idle." As the "telegraph officials cannot be the judges of the comparative urgency of messages," it authorises the "Director-General to introduce, in addition to the 'ordinary' class of messages, two other classes, 'deferred' and 'urgent,'" the latter taking priority, and the former following the ordinary, when they have been worked out, the rates being :—Urgent, Rs. 2 ; ordinary, Rs. 1 ; deferred, Rs. ½, with free address. His Excellency the Governor-General in Council "believes that the introduction of the deferred message system . . . will prove a very great convenience to the public in improving the service for transmission of really urgent messages, and will enable a large reduction in

Digitized by Google

average cost of telegraphing to be made, owing to the facilities it would give for utilising the wires for a greater proportion of the twenty-four hours than is possible under the present system." The special suitability of the deferred system to the long distances in India is exemplified by the condition that the Department does not bind itself to deliver these messages at their destination before early the following morning. Although the nature of traffic thus provided for in India would largely be carried by the post in this country, it is vital evidence to the existence of unearned revenue and undeveloped public facility that the system of "deferred" messages has been adopted in our great dependency. The Departmental Report for 1882-83 gives the total percentage of each class of inland messages dealt with in the last two years as follows :—

STATE MESSAGES.	1881-82.	1882-83.	PRIVATE MESSAGES.	1881-82.	1882-83.
Local	0·65	1·04	Local	0·43	0·64
Deferred	62·70	56·06	Deferred	22·03	32·06
Ordinary	7·12	11·10	Ordinary	72·64	60·90
Urgent	29·53	31·80	Urgent	4·90	6·40

The large increase in the last year of private deferred messages over ordinary shows the popularity of the former class. The value of the inland traffic in the above two years, and in the previous two, before the new system was introduced, shows great encouragement, viz., under private messages.

	Number.	Value Rs.
1879-80	1,037,330	15,32,153
1880-81	1,044,107	14,08,582
1881-82	1,035,137	13,16,851
1882-83	1,189,437	13,86,630

The increase in wire mileage between the last two years was as 58,219 to 61,184.

LEGAL.

Muirhead v. the Direct United States Cable Company.

This case came before Baron Huddleston in the High Court of Justice on the 24th inst. Mr. Webster, Q.C., Mr. R. S. Wright, and Mr. Moulton were counsel for the plaintiff; Mr. Finlay, Q.C., and Mr. Hunter appeared for the defendants.

This was an action for the breach of an agreement by which the defendants acquired the right to use upon their telegraph cable between Ireland and America an invention known as the duplex system, of which the plaintiff was the patentee. The agreement was entered into in August, 1877, and it was provided, among other things, that while the duplex system should "operate satisfactorily" the defendants should pay for its use £2,000 a year, to be paid quarterly; and it was further provided by another article in the agreement that if a total interruption of telegraphic communication took place payment of this sum should cease during such interruption. In conformity with this agreement, the duplex system was applied to the defendants' cable in 1877, and it was admitted operated satisfactorily until April, 1882, when a fault was discovered in the cable, which rendered the duplex system useless. Messages, however, continued to be sent backwards and forwards on the simplex system, and the royalties continued to be paid until the following year, when the defendants, relying upon their agreement, held they were not bound to pay the instalments, as the duplex system, through no fault of their own, had ceased to "operate satisfactorily." Since then two quarters' payments had become due, to recover which the present action was brought. The question between the parties turned upon the construction to be put upon the agreement, the plaintiff contending that the words "operate satisfactorily" meant while the system as a system should operate satisfactorily, independent of its applicability to the cable, and, further, that if, as a fact, the system had not worked satisfactorily, this was because the defendants had failed to carry out an implied obligation to maintain the line in reasonable and proper repair. The defendants, on the other hand, disputed that there was any such implied obligation, and contended that the contract was dependent upon the satisfactory operation of the system, unless the failure to operate satisfactorily was brought about by some fault or neglect of their own. With regard to the facts, it was proved that the system had suddenly ceased to work satisfactorily in April, 1882, and that the cause of its so doing could not be ascertained. The locality of the fault, however, was well known, but to remedy it, it was shown, would involve an outlay of between £30,000 and £80,000, and that the messages could still be sent on the simplex system without it. The defendants urged that to incur such an expense was unreasonable, and was not required by the contract.

Baron HUDDLESTON, at the conclusion of the evidence, gave judgment in favour of the plaintiff. The fair meaning of the section which contained the words "should operate satisfactorily" was that the royalties should be paid so long as the duplex system operated satisfactorily upon the state of things as it then was and on the line which the defendants had, and this implied that the defendants should keep their line in that condition, and do nothing to prevent the successful operation of the system. It was undisputed that the duplex system was applied and did operate satisfactorily for five years, and it was for the defendants to show why they should not pay the instalments which had subsequently become due. They had not shown that the fault was in any way due to the plaintiff; but he did not decide the case against them for failure of proof, but because it was clear there was a fault in 1882 which had not existed in 1877 when the duplex system was applied to the cable. Was this a fault which was contemplated by the agreement? There was a clause which provided what should be done in case of a total interruption, but the contract was silent as to what should be done if the defendants did not repair. It was clear that the repair was feasible, if costly, while it had also been shown that the company had a reserve fund of no less than £340,000. Ought they, then, to repair? He was of opinion that they ought, and that if they ceased to make their line available for the application of the plaintiff's system they were bound to pay under the agreement. He therefore gave judgment for the plaintiff for £1,000, with interest, but as the case was an important one execution would be stayed upon terms.

Central News v. Eastern Telegraph Company.

An application for a new trial of this case was made on Thursday, before Mr. Justice Field, Mr. Justice Manisty, and Mr. Justice Lopes, in the Queen's Bench Division. The Court was of opinion that it would be useless to proceed with the matter until the Lord Chief Justice gave his judgment on further consideration, and the arguments were therefore not proceeded with.

NOTES.

NEW CABLE.—A telegram from Hong Kong, dated June 27, announces the opening of the Haiphong direct cable.

THE TELEPHONE IN GERMANY.—The town of Wilhelmshafen will shortly have a telephone exchange at work.

MAGNETIC OBSERVATORY AT ROME.—It is proposed by the Italian Government to establish a central magnetic observatory at Rome.

ANOTHER MEMORIAL.—A memorial to the Postmaster-General on the subject of telephony is being got up in Birkdale, near Liverpool.

INDIA RUBBER COMPANY.—The Bill of the India Rubber, Gutta Percha, and Telegraph Works Company was read a third time in the House of Commons on Monday.

METROPOLITAN BRUSH COMPANY.—A notice has appeared asking creditors of this company to send in their claims before 28th inst. to the liquidators at No. 2, Walbrook, E.C.

MEETING.—The twenty-fourth half-yearly ordinary general meeting of the Eastern Telegraph Company is to be held at 1 p.m. on Thursday next, at the Cannon-street Hotel.

CHINA.—The Great Northern Telegraph Company announce that a uniform rate of 10s. per word will now be charged for messages from the United Kingdom to all land line stations in China.

THE INSTITUTE OF CHEMISTRY.—A petition has been presented to Her Majesty by Mr. William Odling, M.A., F.R.S., and others, praying for the grant of a charter of incorporation to this Institute.

MANGANESE.—M. E. J. Maumené states that manganese exists in more or less quantities in vegetable matter. Fruits (he says) contain a notable proportion of manganese, as also do coffee and tea.

PROVISIONAL ORDER BILL.—Electric Lighting Provisional Order Bill No. 4 was passed through committee in the House of Lords on Monday last without amendment, and was reported to the House.

AMALGAMATION OF GAS COMPANIES.—The South Metropolitan Gas Company has absorbed the Woolwich, Plumstead, and Charlton Gas Consumers' Company and the Woolwich Equitable Gas Company.

HARROGATE ELECTRO-HYDROPATHIC COMPANY.—Mr. T. F. Smith, of 11, Queen Victoria-street, E.C., has been appointed official liquidator of this company, and all claims should be sent to him before the 14th inst.

CONVERSAZIONE AT KING'S COLLEGE.—A *conversazione* was given at King's College on Thursday evening by Professor Grylls Adams, President of the Society of Telegraph Engineers, about which we shall have more to say in our next issue.

OVERHEAD WIRES IN BRISTOL.—From our "Legal" column it will be seen that the Corporation of Bristol have claimed their right to the control of overhead wires in that city, and that this right has been legally recognised where wires pass over their freehold land.

THE LATE SIR WILLIAM SIEMENS.—A meeting was held on Thursday, the 26th ult., at the Institution of Civil Engineers, to consider what steps should be taken to raise an engineers' memorial to the late Sir William Siemens. A report will be found in another column.

PERSONAL.—We understand that Mr. J. S. Beeman, who has for two years past held the post of engineer and electrician to the South Eastern and Provincial Brush Electric Light Companies, is leaving their service at the end of the present month, in consequence of the change in the character of the company's business.

RESIGNATION.—We learn that Mr. C. H. Capito is leaving the Electrical Power Storage Company, in which he has held the position of chief electrical engineer for the last two years, and has now taken offices at 23, Queen Anne's-gate, S.W., in order to devote himself to the profession of a consulting engineer.

HEDGES' CUT-OUTS.—Mr. Killingworth Hedges has received the following certificate from the Technical Commission of the Vienna Exhibition:—"Hedges' patent cut-outs have been usefully employed in the work of the Technical Scientific Commission, and have proved themselves most admirably adapted to the ends in view."

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of June was 3,531, estimated to produce £3,150, against 3,120 messages, producing £2,688, in the corresponding month of last year. The traffic receipts for the month of March, estimated at £3,200, realised £3,296.

OVERHEAD WIRES.—The Wandsworth Board of Works has written to the local authorities of London pointing out that the Court of Appeal have reversed Mr. Justice Stephen's judgment restraining the erection of overhead wires in its district, and asking whether the local authorities will contribute to the cost of an appeal to the House of Lords.

THUNDERSTORM IN AUSTRIA.—*The Times* Vienna correspondent telegraphed under date June 29, as follows:—"A fearful thunderstorm broke suddenly yesterday over some workmen employed on the Lemberg-Czernowitz Railway. Three of them were killed, one was wounded, and five are missing. A train conveying surgeons and medicines has been sent to their assistance."

INTERNATIONAL PATENTS CONVENTION.—An Order in Council under the provisions of the Patents, Designs, and Trade Marks Acts, 1883, section 103, giving effect to the recent convention acceded to by Her Majesty's Government for the international protection of inventions, designs, and trade marks has just been issued, and will take effect from the 7th inst.

UNDERGROUND WIRES IN NEW YORK.—The Bill requiring all telegraph, telephone, and electric light wires in New York State to be put underground has been signed by Governor Cleveland. The Bill only applies to cities having 500,000 inhabitants or over. The wires are all to be buried by November 1st, 1885, or they will be removed by the local authorities.

ICHABOD.—A Paris paper says:—"The famous 'Métropolitain Electrique' of the Montmartre Boulevard, which used every evening to throw floods of light on obscure passers by, has ceased to exist. This company, whose lot was bound up with that of the Société Nouvelle, has suffered misfortune like the latter, and has consequently been obliged to abandon the spacious premises in which it had established itself."

POSTAL TELEGRAPHS.—The revenue derived from the Post Office telegraphs for the four quarters of the official year ending 30th June last was:—September quarter, £485,000; December, £435,000; March, £390,000; June, £440,000; or a total for the year of £1,750,000. For the year ending 30th

Digitized by Google

June, 1883, the total revenue for the year was £1,735,000, so that the above figures show an increase of £15,000.

THUNDERSTORMS IN AMERICA.—According to a telegram from *The Times* correspondent at Philadelphia, the period of protracted heat and drought was broken on the 25th ult. in the Northern States by severe storms, much damage being caused by the lightning. Four persons were killed and ten injured by thunderbolts in Western Pennsylvania; two were killed in Wisconsin, and one was killed at Richfield Springs, New York.

NEW BOOK.—We have received from America a Government "Report on the Exhibits at the Crystal Palace Electrical Exhibition, 1882." It seems strange that we should have to depend upon a foreign country for a report on an exhibition of such importance as this one, for, so far as we know, no report of this kind has been issued in this country, unless Professor Adams's address to the Society of Telegraph Engineers be looked upon in this light.

DEATH OF MR. WATTS.—We regret to have to announce the death of Mr. Henry Watts, the well-known editor of Watts's "Dictionary of Chemistry," which took place at his residence, 51, King Henry's-road, South Hampstead, N.W., on the 30th ult. Mr. Watts's death will be widely felt not only amongst chemists but also among scientific men generally. He was a Fellow of the Royal Society, and a member of many others. He died at the age of sixty-nine.

ELECTRIC LIGHTING ON SHIPS.—The "Tasmania," which is the latest addition to the fleet of the Peninsular and Oriental Company, went for her trial trip a few days since, when an average speed of 15½ knots was obtained. She is 400ft. long, 45ft. beam, and 31½ft. deep, her tonnage being 4,500 gross, and h.-p. 4,000. She has been built by Messrs. Caird and Co., of Greenock, and has been fitted with incandescent lamps by Messrs. Siemens Bros. She sails from London on the 16th instant.

JOINT STOCK COMPANIES.—Notice is given in the *London Gazette* for the 27th June that the following companies will be struck off the register at the end of three months unless cause is shown to the contrary:—Anglo-Spanish Telegraph Company, Direct American Telegraph Company, Direct Atlantic Telegraph Company, Economic Telegram Company, Electric and General Engineering Company, Globe Telegraph Company, New Atlantic Telegraph Company, North Atlantic Cable Company.

COMMUNICATION ON TRAINS.—The *Ville de Paris* says:—"The Minister of Public Works has just invited the railway companies to adopt from now until the 1st July, 1885, apparatus to enable travellers who may be the victims of assaults to warn the officials of the train. These must be fitted in all express trains which travel 25 kilometres without a stop. No particular class of apparatus is insisted upon, and the companies are allowed to choose between mechanical, pneumatic, and electrical devices."

CARBON FOR BATTERIES.—M. Max Nische Niesky recommends the following process for making carbons for batteries: Take coke of good quality, crush it, and mix with coal tar. Compress the paste thus obtained in iron or bronze moulds and leave for several days. Then place in a furnace and gradually heat to a white heat without exposing the material directly to the flame; maintain this temperature for six to eight hours, then put out the fire and leave the moulds until cool, when the carbons can be withdrawn.

EASTERN TELEGRAPH COMPANY.—Subject to the final audit, the accounts of this company show, after placing £65,000 to the reserve fund, a balance available for dividend sufficient to pay the fixed dividend of 3s. per share, less income tax, being at the rate of 6 per cent. per annum on the preference shares, and a final dividend of 2s. 6d. per share with a bonus of 1s. per share, free of income-tax, on the ordinary shares, making with previous payments on account a total dividend of 6 per cent. for the year ending March 31, 1884, and carrying forward a balance of about £2,500.

TELEPHONE COMPANIES.—In the House of Commons, on Monday last, Mr. O'Shea asked the Postmaster-General whether in deciding on any suggestions which, in accordance with his invitation, might be laid before him by telephone companies, he would take care to exact such conditions as might protect the public against the evil effect of private monopolies which might be created by the amalgamation of, or by arrangements between, the companies.—Mr. Fawcett assured the hon. member that the considerations to which he referred would be carefully taken into account in dealing with the question of telephone communication.

THE NEW ORLEANS EXHIBITION.—The following details relating to this exhibition are of interest. The main building will contain 1,656,000 square feet, requiring 9,000,000ft. of lumber, 4,500 kegs of nails, and 5,000 boxes of glass, in its construction. It will be 60ft. high, with a tower 115ft., and it will have a music-hall in the centre with a seating capacity of 11,000. To light the building there will be 15,000 incandescent lamps, and the steam required for the whole structure will be upwards of 3,000 horse-power. About 1,000 men are engaged on the work of the main buildings, which will be ready for the reception of exhibits in August next.

THE NEW ATLANTIC CABLE.—The cable steamer "Faraday," which has been laying a portion of the Bennett-Mackay Atlantic cable, arrived at Queenstown on Thursday morning from Ballinskellig, on the west coast of Ireland. She commenced on June 28 to lay the shore end from the station at Waterville, and by July 1 had paid out 200 miles, which was successfully buoyed, and the "Faraday" returned to Queenstown to coal. She will not be long in receiving her supply, as three steam colliers are in Queenstown Harbour, sent direct from London for the purpose. On leaving she will proceed to pay out the 1,500 miles of cable she has on board, which will be spliced to the 850 already laid from the American shore, and it is hoped this will be accomplished in about a fortnight from her departure.

SUNDAY WORK IN POST OFFICES.—It appears from a statement of Mr. Fawcett's, in reply to recent questions in the House of Commons, that Sunday work in the Post Office in London has always been an exception, while in the provincial offices it has always existed. By the new classification, however, in 1881, the position of sorting clerks and telegraphists in the provincial offices with regard to Sunday work was considerably improved, as they are not ordinarily called upon to do more than eight hours' work in four Sundays, and if employed for a longer period than this are paid for overtime. When asked why such Sunday work was reckoned exceptional in London and not in the provinces, Mr. Fawcett said that there was less Sunday work in London, there being no delivery on that day.

BLESSING A LIGHTNING CONDUCTOR.—A remarkable service was conducted at Chichester on Saturday. In November last, during a heavy thunderstorm, the lightning conductor to

Digitized by Google

the cathedral spire was shattered, the building escaping without injury, as was recorded in these columns at the time. The dangerous work of replacing the conductor has just been completed without accident, and at the close of the afternoon service on Saturday the Bishop of Chichester, Dean Burgon, Archdeacon Walker, and other clergy, followed by the choir, proceeded from the Cathedral to the spot at which the conductor enters a well. Here the choir chanted a psalm and sang a hymn, and the archdeacon, dean, and bishop offered prayer. An address, founded on the 37th chapter of Job, was delivered by the bishop, and at the close of the service a peal was rung on the Cathedral bells.

Arc Lamps on Incandescent Circuits.—A correspondent writes from Fall River, U.S.A., as follows:—"The Edison Electric Illuminating Company, of Brockton, Mass., are now using in connection with their incandescent system the 'Pilsen' arc lamp, with results which have exceeded their best expectations. They are placed on the same wires which supply current for the incandescent lamps, and are run two in service on each side of the system without the use of resistance coils, and give a very brilliant and steady light. The large porcelain globes not only give a better diffusion than the plain or frosted glass shades in common use with other arc lamps, but render almost imperceptible the occasional slight flickering which attends the burning of the best arc lamps in existence. In addition they are noiseless and economical, and compare favourably with any arc light in use in this country."

New Battery.—The *Bulletin* de la Compagnie Internationale des Téléphones describes a new battery that has been brought to its notice. The negative pole is of iron, and is separated from the other pole, which is of carbon, by a porous jar. The exciting liquid is a very dilute solution of commercial nitric acid. The negative electrode is made up of strips of iron closely bound together by two bands. The carbon composing the other electrode is in the shape of several hollow sticks perforated with holes. The whole is placed in a paraffined wooden box, and the tops of the electrodes are also paraffined. From experiments made with this battery it appears that neither current nor E.M.F. varied after 53 hours' working on a circuit formed of 36 volt Swan lamps requiring 8 amperes of current. It will work for 72 hours at the least without being looked to, and when exhausted only requires a little acid. It is somewhat cumbersome, however, as a battery of 2 cubic meters in size is required for lighting five lamps of a total candle-power of 40 candles.

The United Telephone Company.—In last week's Notes we stated that the United Telephone Company had bought up the London and Globe Company. The following paragraph in *The Standard* of Monday last throws a little additional light on this proceeding. It says:—"An agreement has just been concluded between the two Telephone Companies hitherto in existence in London, under which the United Telephone Company acquires the entire business, goodwill, and plant, together with the patents, of the London and Globe Company in the United Kingdom, for a sum of £25,000, to be paid in cash, and for a consideration of three-eighths interest in all profits, shares, or pecuniary advantage derived from the issue by the United Telephone Company of any subsidiary companies, the United Telephone Company thus reserving to itself five-eighths of such profits. It is also agreed that all litigation is to be stayed forthwith, and the appeal to the House of Lords with regard to the validity of the Edison patent is to be withdrawn, thus giving the United Telephone Company a complete monopoly of the telephone business of the United Kingdom, and rendering the Edison patent unassailable."

Telephonic Communication with Clubs.—In the House of Commons, on Thursday week, the 26th ult., Mr. Houldsworth asked the Postmaster-General whether he was aware that press news is supplied to the Ellesmere, Russell, Central, and 13 other clubs in Manchester; whether the department had power under the Act of Parliament to restrain the members of the said clubs from using telephonic communication for their own private business and affairs between these clubs; and whether he was prepared to withdraw the interdict issued by the department so far as applies to telephonic communication between clubs simultaneously supplied with the press news.—Mr. Fawcett said in reply that he was aware that press news was supplied to the clubs mentioned, as well as others in Manchester. The question of the legality of telephonic communication between separate clubs was quite distinct from that of the conditions regulating the supply of press news. He had already indicated what the latter conditions were in his reply to the hon. member's question of the 17th June (vide *The Electrician*, June 21st), and he felt that it would be inconvenient to enter upon a discussion of the legal position of the Post Office with regard to telephonic communication in reply to a question.

New Company.—A new company has been formed, under the title of the Electric Tricycle, Carriage, Boat, and Machinery Syndicate. The capital is to be subscribed by 100 subscriptions of £50 each, payable by instalments. Subscribers are to be entitled to be supplied with a tricycle or other apparatus in the syndicate's price list to the full value of his subscription, and are to be allowed to pay for the same by their subscription and dividend accounts being debited with the amount. The syndicate's electric tricycle is to be "capable of carrying two persons, and fitted with a battery and motor of sufficient power to propel the vehicle on level ground at the rate of six miles per hour, pedals being added for the sake of exercise and for obtaining a higher rate of speed when desired," and for all these benefits subscribers are to pay £50. If the battery is a primary battery the expense of maintenance will soon begin to tell on the subscriber's pocket; if a secondary battery, he must get it charged now and again, and he will not find people to do that for nothing. If he is anxious for an electric tricycle, let him have one built by a private firm and fitted by an electrician, and we do not think he will need to subscribe to the long-named syndicate, nor will his tricycle cost him £50.

The Faure-Sellon Volckmar Accumulator.—By invitation of Sir Daniel Cooper a considerable number of electricians and others interested in the progress of electric lighting assembled on the evening of the 29th ult., at 6, De Vere-gardens, Kensington Palace, at a *conversazione*, the main feature of interest being the illumination carried out by means of a large number of Swan incandescent lamps worked by the above-mentioned accumulator. This illustration of the capabilities of the apparatus was effected without a single hitch, the lamps in the various apartments being throughout the evening maintained at the same candle-power—one considerably above their nominal 20 candles. In the entrance-hall an illuminated fountain, worked by a small electric motor, in its turn worked by an accumulator, first attracted attention. A working model of Reckenzaun's electric railway, a number of "fairy lamps" worked by pocket accumulators, and other apparatus were also inspected with interest. A neatly and solidly-constructed 1 horse-power cell, weighing

Digitized by Google

90lb., devised and exhibited by Mr. J. S. Sellon, was stated to embody some recent improvements. Great satisfaction was expressed by many of the visitors at the perfect success with which all the arrangements were carried out, and a splendid and tasteful illumination realised.

THE TELEPHONE IN FRANCE.—The following Projet de Loi has been laid before the Chamber of Deputies:—Article 1. The working of telephone lines conceded to private enterprise by the Minister of Posts and Telegraphs cannot be authorised for a longer period than five years, and under conditions fixed by a specification. This specification should stipulate, for the State's profit, for a tax of 10 per cent. at the least on the gross receipts. Article 2. These lines shall be worked either as permanent installations at the houses of individuals or as public exchanges. Article 3. The Minister of Posts and Telegraphs shall fix the tax to be paid for communications by means of public exchanges under the conditions of the law of April 5, 1878. He shall also fix, under the same conditions, the taxes for telephonic communications that the State might establish between towns. Dated Paris, 21st June, 1884. This law is merely an extension of that decreed on 26th June, 1879, which limited the concession of the right to erect and work telephone lines to five years, and reserved a tax of 10 per cent. on the gross receipts for the State. To show how profitable this tax has been we may mention that in 1879 it brought 2,424fr. into the treasury; in 1880, 15,616fr.; in 1881, 55,290fr.; in 1882, 142,637fr.; and in 1883, 217,145fr., whilst for the first quarter of 1884 it amounted to 63,353fr., and the second quarter is estimated to show a receipt of about 70,000fr. The concessions made in 1879 expire on the 8th September next.

FRICTIONAL MACHINES AND MOISTURE.—The results of R. Krüger's experiments in this direction may be summarised as follows:—1. The connection between the strength of the current of an induction machine and the moisture may be expressed by the formula $i = i_0 - a\rho^2 = i_0\left(1 - \frac{\rho^2}{\rho_0^2}\right)$; in which i is that strength of current which would be obtained if there were no moisture at all, and ρ_0 is that degree of moisture at which the machine would not work. 3. This formula holds for any degree of relative moisture with perfect accuracy. 2. The constant $\rho_0 = \sqrt{\frac{i_0}{a}}$ is greater as the velocity of rotation increases; that is, when the machine is rotated with greater velocity, its current first disappears at higher degrees of moisture than when the rotation is less rapid. 3. The quantity of electricity given by one turn of the plate when there is no moisture is essentially independent of the velocity of rotation; and the quantity of electricity which in this case passes through the section of the conducting wire amounts to $458{,}33\cdot80^5$ electrostatic units. Some observations intended to ascertain how far the current depends on the distance of the points from the movable plate, and, on the other hand, on the distance of the plates from each other, showed a decrease of strength with greater distance; but it was not possible to establish a definite law.—Translation of article in Wiedemann's *Annalen*, from the *Phil. Mag.* for July.

ATMOSPHERIC DUST AND AURORÆ.—Mr. Alexander McAdie, of Cambridge, Mass., writes to *Nature* as follows:—"I have had frequent occasion to note the intensity of the so-called 'rainband,' an absorption-band of terrestrial origin, due probably to the dust and water-vapour present in the atmosphere, and of just less refrangibility than the less refrangible of the D lines, and have at present two continuous records of observations, taken, in the main, five times a day, running back a year and a half or so. I have also a very thorough list of the auroral displays which have occurred for the same period in this vicinity. Granting that the aurora is an electric discharge in high regions of the atmosphere, or, more accurately, where its density is inappreciable compared with that at the earth's surface, and knowing that according to recent experiments (by Dr. Lodge and Mr. John Aitken) an electric discharge is capable of precipitating the dust particles in the atmosphere, it should follow that at times of auroral display, or immediately following, the intensity of this rain band should be at a minimum. Searching the records to ascertain if any such correspondence could be noticed, it is quite astonishing to find how distinct and well marked this variation in the intensity of the rain band at times of auroral occurrence is. The atmosphere is full of fine dust particles, and our very general though not yet decisively proven belief is that the aurora is somewhat of a glowlike discharge from electrified air strata, in whose vicinity the density of the dielectric is inconsiderable. The direct inference is that at such times the fine dust and vapour particles are deposited, made to settle, or uniting together, form an agglomeration, and become perhaps cloud neuclei. Perhaps other evidence on this matter can be elicited."

POSTAL TELEGRAPH CLERKS.—The following report appears in a recent issue of the *Birmingham Daily Post*:—"An enthusiastic meeting of the telegraph clerks was held at the Coffeehouse, Bull-street, on Saturday evening, for the purpose of receiving the report of the two delegates who attended the annual conference which was held at the Grand Hotel, Birmingham, on Whit Sunday. A committee was appointed for the ensuing year. The statement made by the two delegates gave great satisfaction to all members present. A hearty and unanimous vote of thanks was accorded them. A resolution was passed empowering the committee to draw up a petition asking the Postmaster-General to give payment for Sunday work. It was stated that while all other branches of the Civil Service worked eight hours per day, six days to the week, the postal telegraph clerks have to work at the rate of fifty hours per week, through having to perform Sunday labour about every four or six weeks. In London the male staff perform the night duty, while the Sunday work is paid for. Their provincial brethren cannot see the justice of this distinction, more especially as the telegraph companies used to pay for Sunday labour both in London and the provinces. In the Bristol offices soldiers are employed belonging to the Royal Engineers, who receive extra remuneration for Sunday work, while the ordinary clerks, who work side by side with the Engineers, receive no Sunday pay. This is looked upon as an injustice. Extracts were read from letters received by the Scotch clerks from several M.P.'s, showing their sympathy with the telegraph clerks, and promising assistance to remove the anomalies. The question of overtime and the practice in vogue at the Birmingham office was spoken of as one calculated to cause dissatisfaction, and thereby prejudicial to the interests of the public service.

ELECTRIC PROPERTIES OF FLAMES. — In Wiedemann's *Annalen*, Herr J. Collert describes the results of investigations on this subject, of which the following abstract appears in the Chemical Society's *Journal* for June:—"This investigation is a continuation of Hankel's researches on the electrical properties of the Bunsen and alcohol flames. The method of experiment was as follows:—A spiral of platinum was placed in the flame symmetrically with its axis, and connected with one pole of a Hankel electrometer, the other pole being in

Digitized by Google

connection with the burner; the electrometer was also connected by a commutator with the poles of a zinc-copper pile conducting to earth. The principal results of the investigation are as follow:—I. The difference of potential is dependent on the material and the temperature of the mouth of the burner; an electro-potential series of the materials of which the burners are constructed can be arranged, of which iron is the most negative. II. The difference of potential is also conditioned by the position of the spiral; the point at which the greatest electromotive force is produced coincides probably with that of maximum temperature. This latter result probably represents the sum of several conflicting causes—firstly, by the rise of temperature the platinum is positively electrified; secondly, by contact with the hydrogen and carbonic oxide gas it is negatively electrified; and thirdly, in the cooler parts of the flame it is positively electrified by contact with steam and carbonic anhydride. As regards the second of these points, the experiments of Deville tend to show that the higher the temperature, the greater proportion of free hydrogen and carbonic oxide present; whilst Grove has shown that platinum is negatively electrified when in contact with these gases. III. The results obtained by the author agree with those of Elster and Geitl; the former finds for the E.M.F. of a platinum spiral in a Bunsen flame = 1·95 Daniell, in an alcohol flame = 1·43 Daniell; while the latter obtained the values 1·92 and 1·44 Daniell respectively.

Society of Telegraph Engineers.—On Friday a conference of the members of this society was held at the International Health Exhibition, when papers by Mr. Crompton and Dr. Stone were read. The former dealt with "Electric Lighting in Relation to Health," and the following is a syllabus of his paper:—Conditions of life under artificial light not so favourable to health as those under sunlight; causes of this (*a*) Those affecting the general health—(*b*) Those affecting the eyesight more particularly. Electric light nearest approaches sunlight, is therefore most favourable to health of all artificial illuminants. Comparison of the heating and air-vitiating effects of eleven different illuminants. Effects on the general health of insufficient light. Why artificial light, previous to electric light, invariably insufficient. Lighting by the arc and by incandescence; proper uses of both kinds. Effects of electric light on the eyesight. Fatigue to the eyesight from insufficient light, from unsteadiness, from bad colour. Comparative steadiness of arc and incandescent light; colour of both classes. Effects on eyesight of workpeople using both classes. Results of various well-known installations, House of Commons, Law Courts, Savoy Theatre, &c. Effects on children. Advantages of electric light indirectly affecting health. Safety. Additional pleasure from flowers, pictures, and all coloured decorative objects. General exhilaration caused by a plentiful supply of pure white well-diffused light. Absurdity of current ideas as to danger to person from use of electricity. Dr. Stone's paper was entitled, "The Physiological Bearing of Electricity on Health." In his opinion electricity as at present used is at once a source of danger, a possible cause of sickness, and a remedy. In all these cases it has been insufficiently studied, and continues to be ill understood. This condition of affairs is probably due to the fact that from the great subdivision of modern science, a competent knowledge of physics as well as of physiology is rarely acquired by the same person, whereas for accurate work it is essential that so powerful an agent should be measured by accepted units. What little has been done by the physiologists is marred by considerable errors as to the force actually in use. Dr. Stone alluded briefly to the dangers to sight, and more minutely to those affecting life and health. He thought the causes of death might be:—1. By catalytic action. 2. By thrombosis of the larger vessels. 3. By shock and syncope, due to action on the cardiac nervous system. Finally, he considered the remedies that might be applied, and the question generally from a physiological point of view. We shall have more to say about these papers and the conference in another issue.

The Electric Light in Mills.—Mr. Oliver Loring, of 19, Airlie-place, Dundee, writes to the *Dundee Advertiser* on this subject as follows:—"I have the pleasure to send you the actual upkeep of 120 incandescent lamps of 100 volts, running for 100 hours, which were fitted up under my superintendence a few months ago in a mill not many miles from Dundee, and which are still in use. The daily register of broken carbons, &c., was kept, and the estimate made at the end of the 100 hours by the manager of the works, who kindly gave me the details, so the source is utterly unbiassed. Besides, there was no skilled electrician in charge of the dynamo and lamps—only their own *employés*. The cost was as follows:—

Broken filaments, 9 at 5s.	£2	5	0
Broken lamps, 5 at 5s.	1	5	0
Broken by accident, 3 at 5s.	0	15	0
Coals, 1 ton	0	8	6
Sperm oil, 1 gallon	0	5	3
Total	£4	18	9

Now, these 120 Swan lamps replaced 169 gas burners, giving an infinitely better and decidedly a purer light than the latter. The cost of gas for 169 jets, consuming 4 cubic feet per hour for the 100 hours, at the rate of Dundee gas per 1,000 cubic feet, would have been—

$4 \times 169 \times 100 \times 3\frac{1}{2}$ shillings	£11	16	7
Less the 5 per cent. discount	0	11	10
Net cost	£11	4	9

This shows a balance of £6 6s. in favour of the electric light. In the above no account was taken for labour, as the attention required for the dynamo was about the same time as that required by a man fetching his safety lamp and lighting the 169 gas burners, since the lights were in various parts of the works. Nothing in either case being allowed for interest and depreciation, supposing we take £20 as such for the electric light for 500 hours, which is about the amount on the prime cost, reckoning it with Mr. Ewing at 8 per cent, this would be £4 additional to be added on. Still we have a balance of £2 6s. in favour of the incandescents. I need scarcely say that £4 for interest and depreciation is, in my opinion, about four times too much. I may also mention that the price of gas, where these are fitted up, is not 3s. 6d., but 4s. 7d. per 1,000 cubic feet, which makes the balance still greater. Without doubt the first outlay seems to be one of the chief causes why the electric light has not been adopted to any great extent in Dundee; but it is not the only one, as Mr. Martin must know by experience. I have found several others during my visits to the mill-owners. Allow me, in conclusion, to state that I trust shortly to produce a lamp costing about 3s. 6d., with an efficiency of three watts per candle-power, and having a life of 1,500 hours. This will reduce the prime cost considerably, and there is no doubt that with increased competition the manufacturers of electrical apparatus will reduce their prices before long. Then the gas companies whose charges are above 3s. per 1,000 cubic feet will find in the new light an antagonist greatly to be feared, and that time is not far distant."

ELECTRO-CHEMISTRY.—Inorganic.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 151.)

Separation of Strontium.—Sr. Atomic weight = 87·5. A cation. Solutions of salts of strontium are slowly decomposed by simple immersion of metallic magnesium; after two days they yield a white deposit of strontium hydrate (S. Kern, *Chem. News*, Vol. XXXIII., p. 112; *Jour. Chem. Soc.*, 1876, Part 1, p. 684). Sodium amalgam decomposed a saturated solution of chloride of strontium with formation of strontium amalgam (Watts's "Dictionary of Chemistry," Vol. III., p. 886; *see* also Vol. VIII., Part 2, p. 1,829). Silicon does not separate strontium from heated fluoride of strontium. I heated to redness a mixture of the two substances, but no chemical change occurred. Caron deposited the metal by fusing its chloride with an alloy of sodium with tin or lead; the reduction was not effected by sodium alone (Watts's "Dictionary of Chemistry, Vol. V., p. 436). Strontium is electro-positive to magnesium, but not to potassium or sodium, in water.

Sir H. Davy was the first to deposit this metal by means of a separate current. He formed into a cup a pasty mass of strontium carbonate with water, placed the cup upon a platinum dish, and filled the cup with mercury as the cathode. By passing a current from 300 voltaic cells from the platinum to the mercury the strontium was deposited upon and absorbed by the mercury. Hare obtained the metal in a similar manner (Watts's "Dictionary of Chemistry," Vol. V., p. 436).

Bunsen obtained strontium in a precisely similar way to that of obtaining manganese (see *ante*), using a salt of strontium instead of one of that metal (Watts's "Dictionary of Chemistry," Vol. II., p. 437). Matthiessen obtained it from the fused chloride in the following manner:—A small porous cell was placed in a porcelain crucible, and both vessels nearly filled with anhydrous chloride of strontium, the level of that in the porous cell being the highest. The salt was melted so that a crust appeared on its surface. The cathode consisted of a thick iron wire, enclosed in the stem of a tobacco pipe, so that only 1-20th of an inch of it projected at the lower end, round which a very thin iron wire was coiled. The anode was a cylinder of sheet iron placed in the outer space. The cathode was immersed in the inner vessel, and the current passed; the metal collected upon it beneath the crust (Watts's "Dictionary of Chemistry," Vol. II., p. 438).

Separation of Barium.—Ba. Atomic weight = 137. A cation. Sodium amalgam separates this metal from a saturated solution of barium chloride at 93° C., and forms an amalgam. (Crookes, *Chem. News*, Vol. VI., p. 194; Watts's "Dictionary of Chemistry," Vol. VI., pp. 252, 253).

Barium amalgam may be prepared electrolytically either by depositing barium into mercury, or by contact of sodium amalgam with solutions of chloride of barium. It is a soft, pasty substance, somewhat gritty (Cailletet, Watts's "Dictionary of Chemistry," Vol. III., p. 886).

Sir H. Davy was the first to deposit barium by means of a separate current. He employed a wet mass of barium hydrate, carbonate, chloride, or nitrate, a cathode of mercury, and a powerful current from 500 voltaic cells, and obtained the metal as an amalgam with the mercury. Hare prepared it in a similar manner from the chilled and moistened chloride by means of a current from 100 cells (Watts's "Dictionary of Chemistry," Vol. I., p. 500). Bunsen electrolysed a boiling hot concentrated and acidulated solution of chloride of barium in a similar way to the one he employed in obtaining manganese, chromium, and calcium. It was more easily obtained than calcium (*see ante*; also *The Chemist*, New Series, Vol. I., p. 686; Watts's "Dictionary of Chemistry," Vol. I., p. 500). Matthiessen obtained banium from its fused chloride in a similar manner to that in which he obtained strontium (*see ante*; also Watts's "Dictionary of Chemistry," Vol. II., p. 438).

A solution of barium nitrate, electrolysed with platinum electrodes, yielded nitric acid at the anode and caustic baryta at the cathode (Sir H. Davy).

Separation of Lithium.—Li. Electro-chemical equivalent = 7. A monad cation. I observed that lithium was not separated by adding crystals of silicon to a fused mixture of the fluorides of lithium and sodium, nor were the crystals corroded or altered in weight. I also fused some fluoride of lithium in an open platinum crucible within a partially covered clay muffle, and electrolysed it by means of a current from six Smee's elements, and two flat platinum wire helices as electrodes, during thirty minutes. The conduction was free, and much gas was evolved from the anode only all the time. The anode was not corroded. A small amount of lithium was deposited upon the platinum cathode, and alloyed with it. By electrolysing a larger mass of the salt, with a current from six Grove's cells and a thick platinum wire cathode enclosed within, but insulated from, a platinum tube, to exclude the air from contact with the deposited lithium, the action was copious; with a gold anode the gold was corroded freely, and particles of it in large quantity floated in the liquid and united the electrodes. The cathode swelled greatly, and its lower end bent itself towards the anode, became quite grey in colour, and split in the direction of its length.

Bunsen was the first person who electro-deposited this metal (Watts's "Dictionary of Chemistry," Vol. III., p. 727). By electrolysing fused chloride of lithium with a current from four or six Bunsen's cells, an anode of gas coke, and a cathode of iron wire, he deposited silver white metal upon the wire (Watts's "Dictionary of Chemistry," Vol. II., p. 437). Schnitzler also electrolysed a mixture of the fused chlorides of lithium and ammonium by a current from 12 Bunsen's cells, and a cathode of iron wire, and obtained metallic lithium (*Jour. Chem. Soc.*, Vol. XXII., p. 961).

Separation of Sodium.—Na. Electro-chemical equivalent = 23. A monad cation. In a solution of sodic chloride, magnesium evolves hydrogen slowly, sodium hydroxide being formed, rendering the solution alkaline (S. Kern, *Jour. Chem. Soc.*, 1876, Part I., p. 684). Beetz observed that under these conditions a black suboxide of magnesium is formed. Carbon, also iron, reduces the melted hydrate or carbonate of sodium at a high temperature, and sets free the metal.

Sir H. Davy first electro-deposited sodium in the year 1807 by moistening its hydrate with water in a platinum capsule, which acted as the anode, dipping a platinum wire cathode in the salt, and using a current from a battery composed of 100 to 200 cells. He also deposited it more easily into mercury in a similar way to that already described under magnesium, and thus obtained an amalgam of the two metals.

In the electrolysis of melted sodic hydrate an anode of either platinum, silver, or copper dissolves in the liquid, and the respective metals are deposited upon the cathode (A. Brester, *Chem. News*, Vol. XVIII., p. 145).

Electrolysis of Sodic Fluoride.—NaF. Molecular weight = 42. I have noticed that crystals of silicon thrown into melted fluoride of sodium evolved bubbles of vapour, which exploded and burned with a yellow flame on arriving at the surface of the liquid. In a second trial, 7 grains of the dry fluoride in powder mixed with one grain of the crystals were heated to redness; the crystals lost ·15 grain in weight. I electrolysed a saturated aqueous solution of sodic fluoride by a current from six Grove's cells with platinum electrodes; gas was evolved from the anode, and emitted a powerful odour of ozone.

Electrolysis of Sodic Chloride. — NaCl. Molecular weight = 58·5. Hisinger and Berzelius electrolysed a solution of common salt with silver electrodes. Gas was evolved at the cathode, and after a time at the anode also. The anode became covered with argentic chloride, the liquid near it contained dissolved chlorine, and the solution near the cathode contained free soda. With lead electrodes the negative wire evolved gas, and received a deposit of crystals of lead, and the anode became coated with plumbic chloride. By electrolysing a solution of common salt, Higgins and Draper observed that chlorine was set free at the anode, and hydrogen gas and soda at the cathode. But if the cathode consisted of mercury sodium amalgam was produced. According to Matthiesen, a fused mixture of the chlorides of calcium and of sodium yields a deposit of the latter metal, when electrolysed in a certain manner (Watts's "Dictionary of Chemistry," Vol. I., p. 715).

(TO BE CONTINUED.)

CORRESPONDENCE.

THE COST OF ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Permit me again, as shortly as possible, to encroach upon your space, and, in the first place, to express my gratification that Professor Ewing has so frankly met me and given the details on which his estimate was based.

For all practical purposes, I think it may be held that with the exception of the dynamos and their cost, the figures of the professor and those given by me agreed. But with regard to the dynamos (apart from cost), allow me to observe that I think my reason for preferring three machines instead of one will be perfectly obvious if you take into consideration the increased efficiency and diminished risk of accident. With only one machine, what would be the result if the belt slipped, or any other interruption were to occur? The whole place would be thrown into darkness in a moment, and endless confusion and annoyance arise; and not only confusion and annoyance, but the risk (indeed, almost certainty), of serious damage both to life, machinery, and goods. But with three machines this could not possibly happen unless through a thorough breakdown in the engine, for it is scarcely possible to conceive that all the three machines would break down and become useless at one and the same time. I venture to say, therefore, that it would be wiser to adopt my plan, as its advantages I am sure would be found to much more than outweigh the minor considerations of economy and efficiency suggested by the professor.

I presume Professor Ewing knows that the illuminating power of Dundee gas is very high, being 27 candles for a 5 feet burner, and for a 4 feet burner 22½ candles. I cannot, therefore, see how he makes out that my 400 lamps of 20 candles and 120 of 10 candles would give a total illumination considerably greater than that given by the 500 4ft. burners. I doubt he will find that it is impossible to use less than one 20 candle lamp for every gas jet. At least that has been my experience in Dundee. I do not know that the mill I referred to differs very much from the majority of other mills in Dundee, or has anything very exceptional in its construction, but, as you say in your article, "figures will prove anything—except facts." It is all very well to say that 500 4ft. burners will burn 1,000,000 cubic feet of gas in 500 hours. I formerly adopted much the same formula in estimates, but when I went to the millowners I was told my figures were much over the sum paid for gas, and I believe it will be found that all the mills in Dundee, almost without exception, use burners to burn not more than 3½ft. per hour, which gives a light equal to about 19 candles. This I believe to be a fact. If, therefore, you adopt 3½ feet per hour, then $3\frac{1}{2} \times 500 \times 500 = 875{,}000$ cubic feet, and at 3s. 6d. per 1,000 feet costs £153 2s. 6d., and with 5 per cent. off for prompt payment £145 9s. 5d. But 500 hours is too much to take, and if 400 hours is taken the cost will then be £116 7s. 6d. against the professor's £166 10s. as the cost of electric light. Do not the above figures, so far as the work in question is concerned, substantially support all that I have said, and may not the difference between the £100 of gas bill actually paid, and the £116 7s. 6d. which we might say they ought to have consumed, be put against the saving through careful manipulation of the gas in combination with the exceptional position and construction of the works?

It is needless for me to occupy your space by noticing the other details the professor gives, as although I might take exception to some of them the difference would not amount to much. I would merely remark that he does not err on the extravagant side.

But the whole thing resolves itself into this. It is quite evident that dynamo machines and incandescent lamps should be made and sold for a mere tithe of what is charged at present, and, until the companies reduce their prices electric lighting can never expect to enter into competition with gas in these mills. I shall be glad if the result of my communication is a substantial reduction in prices, and it was this I had in view in touching upon the matter. In fact it has borne good fruit already, as I have received letters from some of the companies offering to supply me with apparatus at a reduced figure—in one case at about 200 per cent. less than the figures quoted by me for dynamos. The prohibitive prices hitherto charged cannot for a moment be justified, and have been the means of retarding the progress of electric lighting. This is a matter which the shareholders of the various companies should have before them, and I venture to predict that a reduction of prices would be followed by a greatly increased demand, resulting in substantial dividends to the shareholders, fairly and honestly earned. Is not this the secret of the want of success of the various electric light companies? Without exception they have been ruinous to shareholders, who embarked in them as a sound investment. Have any of the companies ever fulfilled the high expectations their prospectuses suggested?

This letter has already reached to a greater length than I anticipated, but I believe it meets all the other minor points started in the letters of your correspondents.—Yours, &c.,

W. C. MARTIN.

Commercial-street, Dundee, 1st July, 1884.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the correspondence going on in your journal under the above heading, I agree with Professor Ewing's estimate of the prime cost of an electric light installation for 500 lamps.

In his estimate for maintenance, however, I would take exception to one or two items. Firstly, I think the cost of coals (8s. per ton) is rather too moderate. Secondly, the item £6, to cover "oil and attendance" is ridiculously small. Most people who have had any practical experience of the working of an installation of 500 lamps will agree with me in saying that it takes all a man's time to attend to the dynamos, belts, lamps, connections, switches, and the numerous other details connected with such an installation. And, furthermore, for proper attention it is necessary that the man in charge should possess more than average intelligence, and be capable of making connections, repairing fuses, detecting faults, &c. Therefore it is only reasonable to allow at least 25s. a week for attendance. Moreover, I believe that where there is a large dynamo working for a number of hours continuously every night, there must be some superior supervision to that of an ordinary workman, otherwise there will be occasional breakdowns, attendant, perhaps, with some injury to the machinery. And repairing of dynamos, we all know, is a costly matter, so that if the expense of an occasional visit of an electrician be added to the expense of a regular attendant, the item for attendance should be set down at something like £80. Then for oil and waste, I do not think 6d. per night too much for these, which alone would make, say, £7 10s. per year. Nothing is set down for renewal of brushes, which in a large machine might cost £2 or £3 per annum.

As to the item "renewal of lamps," Professor Ewing has overshot the mark completely. In an installation under my charge, the breakages, after working 1,000 hours, have been only 15 per cent. Therefore, I should rather allow 50 renewals in a case of 500 lamps for 500 hours, which I think would be ample, and would be £20 instead of £50.

My estimate, therefore, for current cost in the case in question would amount to (assuming the price of coals to be correctly stated) £220 instead of £166, as made out by your correspondent.

In conclusion, I think it only right that people should at length admit the fact that isolated electric lighting is more expensive than gas, and endeavour to reduce the expense both on prime and current cost, rather than continue to persuade themselves that an impossibility can be achieved.—Yours, &c.,

J. ANGELO FAHIE, M.S.T.E. and E.

10, Leinster-street, Dublin, 30th June, 1884.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your article on this subject last week you say that the estimate in my letter of 50 per cent. for renewal of lamps per annum seems enormous. It is founded on the ordinary

Digitized by Google

notion that 1,000 hours may be counted on as the average life of a lamp in its normal state of incandescence. With 500 hours' use this of course involves the replacement of half the lamps yearly on the average. I heartily endorse your remark that this question of the life of lamps needs elucidation. The only figures with any apparent claim to credit that I have seen tend to confirm the ordinary estimate of 1,000 hours, but the statistics hitherto published are astonishingly meagre. There can be no doubt that much information on this point could be given by the manufacturing companies and by users of lamps, and I venture to ask your support in appealing to them for such exact statistics as they can give. With respect to any one type of lamp, we wish to know not only the average life at the normal brightness, but the average life when the same type of lamp is worked at several grades of candle-power under and over the normal. A mass of information of this kind is needed before we can tell the most economical power at which to work, having regard to the proportion which the cost of renewal of lamps bears to the cost of supply of electrical energy in any given installation. Users of lamps would do electrical engineers a most valuable service if wherever the conditions are favourable—that is to say, wherever the electromotive force is uniform, and the number of hours of use easily counted—they would take the trouble to observe and record systematically, and finally to publish the number of hours each lamp of a given type lasts when exposed to a stated electromotive force. And the value of the observations would be enormously enhanced if in any large installation the lamps were divided into two or more groups, with a known small gradation of electromotive force from group to group.—Yours, &c., J. A. EWING.

University College, Dundee, July 1, 1884.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Setting aside the question of central lighting stations, which even the largest companies shrink from undertaking with their present resources, and under the restrictions laid down by the Board of Trade, the all-important question at the present moment is one of price.

Thanks to the pioneering work done by the companies during the past three years, electric lighting has now taken a firm hold on the mind of the public. It is true that we hear a good deal about the public having lost their confidence in it, but this statement must be accepted in a very limited sense. When a man loses his money in any undertaking he generally loses his confidence as well, and in the present instance the investing public have been very heavy losers.

The objections which were urged against the new illuminant three years ago have become obsolete. The fanciful ones concocted by opponents out of the element of danger are scarcely heard of now; while many practical objections, which were true then, have since been overcome. The ground has been cleared, and there is now no difficulty in convincing a man that the electric light is what he ought to have.

Some correspondence has already appeared in your columns with reference to the present depression and the influence of prices. Much has been said, moreover, as to the cost as compared with gas, and several more or less reliable estimates have been published to show that the one is as cheap as the other.

I think, however, that much of this is quite beside the mark, and that the cost as compared with the old illuminant has not so much to do with the question as has the first cost, the cost of the plant.

My experience goes to show that in most cases people are willing to pay a premium on their gas bills for the sake of having what they are now convinced is a better light, but that they will not face the first outlay for plant.

The field which is open for the electric light is a very wide and varied one, but we may divide it broadly into three, in each of which the conditions are different. (1) We have those to whom the light is either a necessity or a luxury, which they are willing to pay for as such. (2) Those who are willing to buy plant and work the light themselves at a moderate cost. (3) Those who in the nature of things cannot provide or work their own plant.

With the first of these the question of price is not a material one, and there is sufficient work here to keep several firms well employed; indeed, it is among this class that the principal amount of work has already been done.

But the electric light cannot become general till it can provide for the wants of the other two classes as well. Of these the one is principally made up of mills, factories, and workshops, while the other includes shops and private houses.

It is to the former of these we have to look principally at the present moment for our custom, and with them the cost of plant is the one serious consideration. They are willing to buy plant and work the light themselves, but they are unwilling to spend any considerable amount of capital in so doing, and moreover there is a general feeling that in a year or so electrical plant will be very much cheaper. Under these circumstances they will not replace their present gas fittings.

The electric light, it is true, can, even at present prices, compete with gas under equal conditions, but what we want to see, and what we believe can be done, is something more than this. We want to see it taking the place of gas, and this is what it can only do to a very limited extent at present prices.

With regard to the supplying of shops and houses, it may be doubted by some whether any business at all is to be done here until the establishment of central lighting stations.

Though I grant that it cannot become general among this class till the establishment of these stations, yet I submit that there is a very large business to be done here which has not yet been touched.

Many shopkeepers, and also householders, would be willing to purchase a small plant, subject to skilled supervision, but here again they are deterred by the price, and there is the additional difficulty of providing motive power. Gas engines would have found a ready market were they not so frightfully expensive.

This is just the field for the use of secondary or primary batteries. We have heard a good deal lately of various new forms of primary batteries for electric lighting, and there is here an extensive field open for a properly organised company, who will supply the batteries and work them by sending round properly qualified inspectors to attend to the re-charging.

It is of course an open question at the present moment whether this can be done at a price which will induce people to substitute the new light for the old one, but if it can be done anywhere near the price of gas the field is a very extensive one.

I think, therefore, that as long as present prices are maintained operations will be comparatively limited, and, moreover, that if those who are now manufacturing dynamos and other electrical plant insist on maintaining the price, other firms in the engineering trade will take up the manufacture, and turn out apparatus at what is recognised in the trade as a fair price for metal and labour.—Yours, &c.,

W. KINGSLAND.

1, East Parade, Leeds, 1st July, 1884.

THE COMMON SENSE OF ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The worth of legislation for the control of new inventions depends in the long run, not so much on public opinion about them, as on the facts themselves when freed from hope, theory, or surmise.

On the 18th August, 1882, a Bill became law entitled "An Act to *Facilitate* and Regulate the Supply of Electricity." This Act embodies the hopes of the English people, born of gazing on the glitter of the two electric exhibitions held previous to the passage of the Bill, and their fears of having to pay too much for the gratification of these hopes. Three assumptions underlie this Act, the truth of which still awaits confirmation by experience. It was assumed,

1. That the construction of insulated underground systems for conveying electric currents of great strength was understood in the year 1882, and required legislative control in the same sense as railways, docks, or canals require State regulation.

2. That the effectual generation and supply of electricity to a large area from a central station was not only feasible, but commercially practicable.

Digitized by Google

3. That the cost of production was known to a nicety, and the conditions of supply so well understood, that the enterprise was sure to be enormously profitable, and therefore fit subject for treatment by way of restriction and penalty.

If these assumptions were not founded on facts, the effect of the Act was either to compel costly experiments under unfavourable conditions, or, by deterring prudent investors from risking capital in an enterprise fettered with impracticable conditions, to postpone *sine die* the time for making a serious experiment on a large scale. The result of two years demonstrates that the restrictions introduced have operated as a complete prohibition of any such experiment.

It is not difficult to show that these assumptions were based on limited experience and on unlimited hope. The experience that exists for laying large insulated cables of copper underground, and for knowing the conditions under which they will remain perfect, is of the slenderest kind now and was almost *nil* then.

When the Bill received the Royal assent, no central generating station existed in England except the experimental station of the Edison Company at Holborn Viaduct.

Again, the Act prescribes conditions in language applicable to a material substance for the sale of something more subtle —viz., a form of energy. The value of energy depends on its capacity for conversion into heat, light, and power. Hence our legislators did not facilitate electric lighting as promised in the title of the Act, when they agreed to clauses preventing companies prescribing particular forms of lamp, such lamps being essential parts of the apparatus required for the conversion of energy into light. Restrictions as to charge would be right and proper when the conditions of production were fully ascertained; but the Act imposed on the companies compulsory supply of light, while leaving them to fight their own battle for the value of the indispensable central site, which value enters as a serious item in the cost of the light.

The inference from this is that the legislative strong meat of 1882 has stunted, if not destroyed, our electrical babe; and that until fostering treatment replaces the ironclad rule of permanent officials, not only the electric light, but the telephone, and every other promising scientific effort will be dwarfed, if not destroyed. The English methods of dealing with great inventions of the nineteenth century will thus be placed in even sharper contrast with those of every other civilised country in the world.—Yours, &c., ARNOLD WHITE.

Devonshire Club, S W.

THE ELECTRIC LIGHTING ACT OF 1882.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your last issue you enter at some length into the vexed question of the cost of electric lighting, and hazard the conjecture whether any one will be bold enough to say that the cost of a central electric light station is more than the cost of a central gas station. Twenty-two months ago the Legislature of this country, after careful scientific examination of the then state of the art of distribution of large currents for lighting purposes, arrived at the conclusion that it was in such a complete and advanced condition that the time had arrived for "facilitating and regulating" it according to the title of the Act—that is to say, for laying down stringent conditions under which the novel experiment of distributing electrical energy on a large scale should first be tried. The question of cost and maintenance will therefore to a very large extent be influenced by the legal conditions under which it has to be undertaken. If these conditions are wise and elastic enough to accommodate the uncertain direction of development of the youngest of the arts, your question may not be long in receiving a practical reply. But if these conditions have been based upon a complete misconception of the *differentiæ* which separate the distribution by pipes of a material substance from the first attempts at distribution of energy in the form of electric current by subterranean copper mains, then the interesting question whether the best and cheapest light in every way is obtainable from the combustion of a hydro-carbon or the incandescence of a carbon filament by distributed electricity may, in England at least, be indefinitely delayed. Which of these prevails is easily ascertainable by an examination of the main special provisions of the Act in the light of past and present experience. The general conception of the Act is that of permitting the laying down of a network of conductors under these general conditions. The undertakers have to specify beforehand—in the absence of guarantee as to demand—the area they will cover at first, and the direction in which they will undertake to extend the mains. They are to bind themselves as to price without any limitations *per contra* as to the cost of the ground, for central site, facility of or compulsory purchase for extension, right of way, or security against injunction for nuisance. They are debarred from any selection of customers, on the ground apparently (although a mistaken one) that as electricity is sold by measure customers are all proportionately profitable. They are expressly interdicted from interference with the most important section of the electrical loop, viz., the lamp, and finally they are given 21 years or less within which to achieve practical success and the return of invested capital. To any one who has had practical experience of even small electrical distributions it is only too apparent in every line of this Act that the conditions of commercial success were not understood by those who framed it to "facilitate" the supply of electricity for lighting purposes, and they allowed themselves to be misled by the analogy of the electric main to a gas pipe. But the supply of electric current is not similar to the carriage of stored-up gas. In the one case a form of energy has to be transformed as wanted, and when once the plant has been set up for a given supply the cost of maintenance will not be proportionately affected by variation in actual consumption. In the other case, a material substance is prepared and stored, and if the consumption is less to-day there is more left over for to-morrow without additional cost. Hence the paramount condition of success at the outset is liberty to select customers, so that the hours of burning may be a maximum, and the mains and machinery kept as little idle as possible. Again, in the case of electric supply, the commercial commodity retailed is light, and the apparatus of conversion—viz., the carbon filament—is only a portion of the endless loop of lead and return in which the dissipation of energy in the form of light is made a maximum. Privilege to select for the consumers that form of lamp which is best adapted to the distribution of potential, and is electrically and commercially most economical is an obvious necessity.

Briefly, what is required for any sort of prospect of success is this,

1. Abolition of areas compulsory and permissive, specified streets, &c. The network of conductors must extend as required round the most favourable site previously selected.

2. Free option to pick and choose customers, and to favour long burning hours clients whilst the station is small.

3. Complete control over the lamps used, the undertakers to sell light or power in standard candle hours or horse-power, and the customer to have no perplexity about units of any kind as compared with gas.

4. Freedom from obligation to transfer the property or to do anything at the end of any period which will compel the revenue to be so taxed as to prevent investors from reaping such profits as may be reasonably looked for in pioneer enterprises of this description.

5. Conditions of safety insulation and regulation of pressure to be maintained of course by suitable regulations.

As it stands at present, the Electric Lighting Act of 1882, so far from facilitating electric supply affords the most complete barrier to its introduction, and will continue to do so until repealed. The notion that there was a danger of the upgrowth of a great monopoly is an instance of the danger of premature legislation in advance for difficulties which have not arisen.

Whilst such important questions as those of triple or multiple conductor systems, central station dynamos, meter measurement, and methods of laying mains and feeders are admitted to have scarcely reached their final solution, is it not too much to expect that wise commercial men shall plunge into a new undertaking under conditions which do not give them the very freest scope to feel their way gradually and modify their methods of charge and supply, in proportion as

Digitized by Google

industrial invention supplies the means for cheapening the cost and widening the area of practicable distribution. The problem of distributing small electric currents by conductors for the purposes of commercial telegraphy was not solved without much experience; but if the more difficult one of distributing currents a thousand or ten thousand times as strong is to be attempted under the trammels of legislative restrictions, we are not likely to have the opportunity of comparing in England, under equally favourable circumstances, the cost of electric and gas supply.—Yours, &c.,

J. A. Fleming.

THE CURRENT-CARRYING CAPACITY OF WIRES.

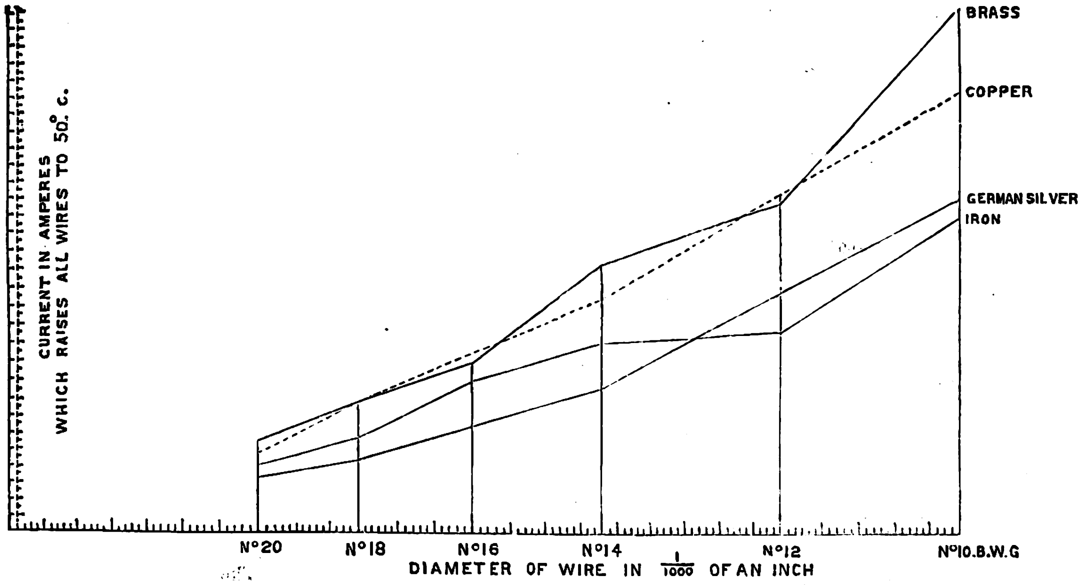
TO THE EDITOR OF THE ELECTRICIAN.

Sir: Your correspondent "Student" asks a question in your last issue relating to a formula quoted from Messrs. Munro and Jamieson's pocket book. This formula purports to give information as to the rise in temperature of a wire carrying a current. It cannot, however, be of any use when obtained, for the reason that the formula in question is not based on accurate physical assumptions. The formula quoted is simply a symbolic expression for the statement that the temperature of a wire becomes stationary when the electrically generated heat balances the heat emitted by radiation in a unit of time, and, as a simple consequence, it follows that for different sized wires of the same metal raised to the same stationary temperature, the square of the heating current ought to vary as the cube of the diameter of the wire.

This result is totally erroneous, and at variance with the result of experiment, and for the reason that the generated heat is removed from a wire insulated in air by *convection* as well as radiation, and in naked wires the former plays the most important part in the dissipation of the energy.

I have recently carried out some experiments on the safe current-carrying capacity of naked wires with just that amount of accuracy sufficient to make the results of practical use without giving them a claim to scientific measurements.

It is necessary to point out that although for different sized wires under given circumstances of atmosphere and enclosure it is possible to obtain a graphic relation between diameter and equi-temperature current, yet the relation is not capable of being expressed as is sometimes done in books by any simple algebraic formula, because, except in the case of conductors wholly buried in homogeneous insulating material of known thermal conductivity, the conditions of heat removal from the wire are too complicated to admit of simple expression; but there are certain cases constantly occurring in practice which it is very useful to have examined. The principal case is that of spiral coils of naked wire insulated in air. Questions of the following description constantly arise:—It is desired to insert in series with an arc lamp a German silver resistance coil, open to the air, capable of carrying safely eight amperes, and having a resistance of four ohms. What sized wire, and what length shall be selected? To provide data for answering the above I had prepared a series of coils of naked wire of German silver, brass, iron, and copper, the sizes of which were Nos. 10, 12, 14, 16, 18, 20 B.W.G. These were coiled in helices on wooden rods, and laid horizontally on a frame. Currents were then sent through them all sufficient to raise every wire to the same temperature, viz., about 50° C., a temperature just bearable to the bare hand. Ample time was allowed to elapse for the temperature to become stationary, and when this was the case the ampere current was recorded in each case. The accompanying diagram records the results of observation. Distances marked off on the horizontal line represent the diameter of the wires in mils. and vertical heights the safe current in amperes. The observations at the stated diameters were marked off, and the points so obtained joined by pieces of straight line. No attempt has been made to "draw a smooth curve by free hand through the points of observation," but the results are given just as obtained. The scale of amperes for the copper is just half that for the iron, brass, and German silver on account of the high conductivity of copper.



Curves showing relation of diameter to safe current.

The results show that the current curve is for the German silver and copper very nearly a straight line; in other words, the current strength which raises different sized wires to the same temperature varies *as the diameter* of the wire within the limits of observation.

A reference to these diagrams is sufficient to give an answer, good for all practical purposes, to the above question. It must be clearly understood that the results in no way apply to the case of covered wires nor to coils other than naked open spirals, insulated and freely open to the air. These results confirm a remark on page 305 of Mr. Sprague's recent excellent book on electricity, that Siemens says experiment shows that safe current varies as diameter simply, and not in the sesquiplicate ratio of diameter. Although from a scientific point of view it would be desirable to carry out experiments of this kind with greater accuracy, yet for all practical purposes the above diagram is sufficiently good—at least, as regards copper and German silver wires. Other useful data could be obtained by taking German silver strip and hoop iron as being frequently used. The introduction into books of formulæ like the one quoted by "Student" may be useful as a material out of which to construct examinations, or "exer-

Digitized by Google

cises for the student," but they do not represent the facts of nature, and are of no practical use. All those tables are also erroneous in which the safe current in amperes has been calculated on the assumption of an equal current density in the wire, *i.e.*, an equal number of amperes per square inch of cross section raises different sized wires to the same temperature, because the law of the diameter simply bestows a higher relative carrying capacity upon small wires than upon large. In the above experiments the current sent through the No. 10 copper wire was at the rate of 3,545 amperes per square inch of section, whereas the current passed through the No. 20 wire was at the rate of 8,316 amperes per square inch, and these very different current densities bring the respective naked copper wire spirals to about the same temperature in air.

Professor Forbes has also been led to the conclusion that the safe current varies as the diameter of the wire, and in his interesting paper on the subject he has given an account of an analogous series of experiments leading to the same conclusions.—Yours, &c., J. A. FLEMING.

RUHMKORFF'S COIL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Last week I received a book entitled "The Electric Light in Our Homes," by Mr. Robert Hammond. On page 18 of this book he says:—"On the table is an electrical apparatus known as a Ruhmkorff coil. In my left hand I hold the wire which leads from the positive, and in my right hand the wire which leads from the negative pole of the coil. When the ends of the two wires are kept a short distance apart the current of electricity from the Ruhmkorff coil does not flow, because it is unable to jump over the intervening space in the open air."

Now, sir, I thought that this was one of the "peculiarities" of the induction coil, being able to send a spark through air, but perhaps I am mistaken. If so, would you or some of your readers kindly point out where my mistake lies. With a coil such as is illustrated on page 18 of this book, I should be very chary about taking the - and + wires in my hands, unless the wires were very well insulated.—Yours, &c.,

ROBERT C. JONES.

Moss Bank, George-street North, Dunedin,
Otago, N.Z. May 23rd, 1884.

ALEXANDER BAIN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the churchyard at The Old Aisle, Kirkintulloch, there is a granite block erected to the memory of Alexander Bain, with the following inscription:—

"ALEXANDER BAIN,
Electrician and telegraph engineer, distinguished for many inventions of the greatest value in electric telegraphy, &c., &c.
Born in the Parish of Watten, Caithness-shire, October, 1810.
Died 2nd January, 1876. Interred here."

Alexander Bain died in the year 1877, and I venture to call your attention to the error in the inscription in the hope that it may be corrected.

Bain's versatile inventive faculties will always rank him amongst the greatest of those who, at a very early date, contributed to the development of the electric telegraph, if not of electric science, and it would be unfortunate if such an error as the one I have pointed out should be allowed to remain.—Yours, &c., A. J. FROST.

Society of Telegraph Engineers and
Electricians, June 28, 1884.

ERRATUM.—In the note to Mr. FitzGerald's letter the last formula (for energy) should read $\frac{E^2S}{l}$.

THE LATE SIR WILLIAM SIEMENS.

A meeting was held on Thursday, the 26th of June, in the hall of the Institution of Civil Engineers, Great George-street, Westminster, for the purpose of considering what steps should be taken to raise an Engineer's Memorial to the late Sir William Siemens. The councils—including past presidents and other officers—of five of the leading engineering societies were summoned to attend, namely, in order of foundation:—The Civil Engineers, the Mechanical Engineers, the Naval Architects, the Iron and Steel Institute, and the Telegraph Engineers.

Amongst those present were the following:—Sir Frederick Abel, C.B., F.R.S.; Mr. W. Anderson, Mr. B. Baker, Mr. J. W. Barry, Mr. J. F. Bateman, F.R.S.; Colonel Bateman-Champain, R.E.; Sir J. W. Bazalgette, C.B.; Sir Henry Bessemer, F.R.S.; Sir Frederick Bramwell, F.R.S.; Mr. Brunlees, Mr. E. A. Cowper, Mr. T. R. Crampton, Mr. R. E. Crompton Sir Charles Hutton Gregory, K.C.M.G.; Mr. George Holmes, Dr. Hopkinson, F.R.S.; Mr. J. S. Jeans, Dr. Pole, F.R.S.; the Earl of Ravensworth, Mr. M. F. Roberts, Mr. J. D'A. Samuda, Mr. J. I. Thornycroft, Mr. F. H. Webb, Mr. R. Price Williams, and Mr. Edward Woods.

On the motion of Lord RAVENSWORTH, seconded by Col. BATEMAN-CHAMPAIN, R.E., Sir Joseph Bazalgette, C.B., as president of the senior engineering society—the Institution of Civil Engineers, was asked to preside.

The CHAIRMAN then offered some explanatory remarks, pointing out that a general desire had been expressed among engineers that some memorial should be raised as a recognition of the great merits and important services rendered to engineering by Sir William Siemens; that it had been ascertained it would be agreeable to the authorities of Westminster Abbey that a window should be erected in that building to the memory of the deceased; that possibly the cost of such a window might amount to between £700 and £800; that it was thought the greatest tribute to the memory of the deceased would be by allowing the largest number of contributors, and that under those circumstances it was deemed advisable to limit the subscriptions to one guinea each, such subscriptions only to be received from a member of one of the five societies named.

Sir CHARLES HUTTON GREGORY, K.C.M.G., then moved, and Mr. EDWARD WOODS, V.P. Inst. C.E., seconded, "That this meeting is of opinion that it would be very desirable to commemorate the distinguished character and attainments of the late Sir William Siemens by erecting to his memory a window in Westminster Abbey."

This proposition, having been spoken to by Lord RAVENSWORTH and Colonel BATEMAN-CHAMPAIN, was unanimously agreed to.

On the motion of Mr. E. A. COWPER, seconded by Mr. T. R. CRAMPTON, it was determined to limit the subscriptions in the first instance to £1 1s.

Mr. BATEMAN, F.R.S., then proposed "That an executive committee of three members from each of the five societies, including in every case the president (five to be a quorum, and with power to act), should be appointed."

The following committee was then agreed to:—

For the Civil Engineers—Sir J. W. Bazalgette, C.B. (president), Sir Frederick Bramwell, F.R.S., and Mr. Woods (vice-presidents).

For the Mechanical Engineers—Mr. I. Lowthian Bell, F.R.S. (president); Sir Joseph Whitworth, Bart., F.R.S.; and Sir William Armstrong, C.B., F.R.S. (past presidents).

For the Naval Architects—The Earl of Ravensworth (president), Mr. Samuda (treasurer), and Sir Edward Reed, K.C.B., F.R.S., M.P. (vice-president).

For the Iron and Steel Institute.—Mr. B. Samuelson, M.P., F.R.S. (president), and His Grace the Duke of Devonshire, K.G., and Sir Henry Bessemer, F.R.S. (senior past presidents).

For the Telegraph Engineers—Professor W. G. Adams, F.R.S. (president), Sir William Thomson, LL.D., F.R.S., and Sir Frederick Abel, C.B. (past presidents).

Mr. James Forrest was requested to act as honorary secretary and treasurer to the committee.

The thanks of the meeting were, on the motion of Sir HENRY BESSEMER, seconded by Mr. SAMUDA, unanimously accorded to Sir Joseph Bazalgette for his services in the chair.

THE TELEPHONE AND FIRE.—As showing one of the many advantages of the telephone, it may be mentioned that the first news of the recent fire at the Theatre Royal, Edinbro', was received by its means at the central fire station within a few minutes of the outbreak.

The Superintendent of the Philadelphia Police and Fire-Alarm Telegraph has seized the wires of the Postal Telegraph Company which are strung on the city's poles, on account of failure of the latter company to put them underground by May 1, according to their agreement.

PHSYCHICAL RELEARCH.—According to the *Daily Telegraph* of 3rd inst. the Phsychical Research Society now numbers amongst its members such well-known electricians as Lord Rayleigh, who is its vice-president, Professors Adams, Balfour Stewart, Schuster, Lodge, and Barrett.

E. W. LANCASTER.—*A letter awaits you.*

THE ELECTRIC LIGHTING ACT.

Our last week's leading article has attracted more attention than we had any reason to expect at the time, and has reopened a question which for a good while past we have been content to let remain closed. We have expressed our opinion so openly and so often on the Electric Lighting Act of 1882 that we can hardly add anything to what we have already urged in objection to it. Time and experience, however, are daily confirming the worst we have said about that mischievious measure, and the subject is now, it seems to us, ripe for action of a more practical kind than mere criticism. From among our correspondence this week touching our remarks on the cost of electric lighting we select two important letters for publication —one from Mr. Arnold White and the other from Dr. J. A. Fleming. Both these writers are known to be deeply interested in the welfare of electric lighting; their letters prove conclusively that they have given careful thought to the subject, and their testimony as to the several causes of the failure of the Act is as trustworthy as any that could be had. We earnestly draw the attention of our readers to these letters, and invite further expressions of opinion, the result either of practical experiment or of local information as touching the municipal interests involved.

From the very first we deprecated the introduction of any Act of Parliament regulating the operations of electric lighting promoters, and we maintained all along that opposition to it should take the form, not of amending its clauses, but of getting it rejected. Long before now the well-meaning but short-sighted supporters of Mr. Chamberlain's Bill have, we should imagine, discovered their mistake. It was useless to seek better terms in a measure whose radical principle was to prevent any terms whatsoever under its provisions being helpful to the system it pretended to regulate. Had it been deliberately drawn up in the interests of the gas companies it could not have been more inimical to the interests of electric lighting companies. The wide-spread ruin which has overtaken these latter is proof that they have profited nothing by the Act, and the fact that there have been virtually, and almost literally, no installations of the electric light under its provisions is proof that nobody could have profited by it even if the attempt had been made. Our best wishes go with the one or two ventures which are being hazarded in spite of the Act; but it is manifest that in the particular circumstances, if they escape failure it will be due to a very liberal interpretation of the clauses of the Act, and not by virtue of any liberality to be found in it. We stated at the time that the Bill was framed in a hostile spirit, though professedly introduced to give legislative encouragement to the new light. It was the sort of legislative encouragement Protectionists give to imports by elaborately benevolent fiscal dues.

But even if we grant that the apparently selfish objects were absent from the minds of the framers of the Act, the fact remains that in practice it has operated as a complete barrier to the introduction of electric lighting, and has therefore failed in its object, if its object was really friendly. The attempt to regulate what nobody—not even experts—thoroughly understood was bound to break down, and no sort of legislation in that direction will ever succeed until electric lighting business has had an opportunity of working in absolute freedom from legislative control. If the great gas purveyors had been saddled with any such conditions as those which have been imposed on the purveyors of electric light at the very outset, there would probably now be no gas supply; yet the problems of gas lighting were never so obscure or so intricate as those which surround the generation and distribution of electricity. The Bill treated the commodity as if it were all cut and dried, and had only to be sold across the counter. As a matter of fact it is in a crude condition still, and must remain so until experiments, and these on the most varied and extended scale, have been tried. It was assumed, as one of our correspondents puts it, that the cost of production was known to a nicety, and the conditions of supply so well understood that they were sure to be enormously profitable; whereas it is still a moot point whether, under any conditions whatever except those of their own choosing, the undertakers of electric lighting could make any profit at all. The conditions required even for possible success are carefully set forth by both our correspondents, and they are in agreement as to what is now needed. There must be freedom to choose their own areas for operation, to choose their customers, to supply what lights they and their several customers may agree upon, and to be exempted from what may justly be called the confiscatory clauses of the Act. To our thinking these propositions mean nothing short of the unconditional repeal of the obstructive part of the

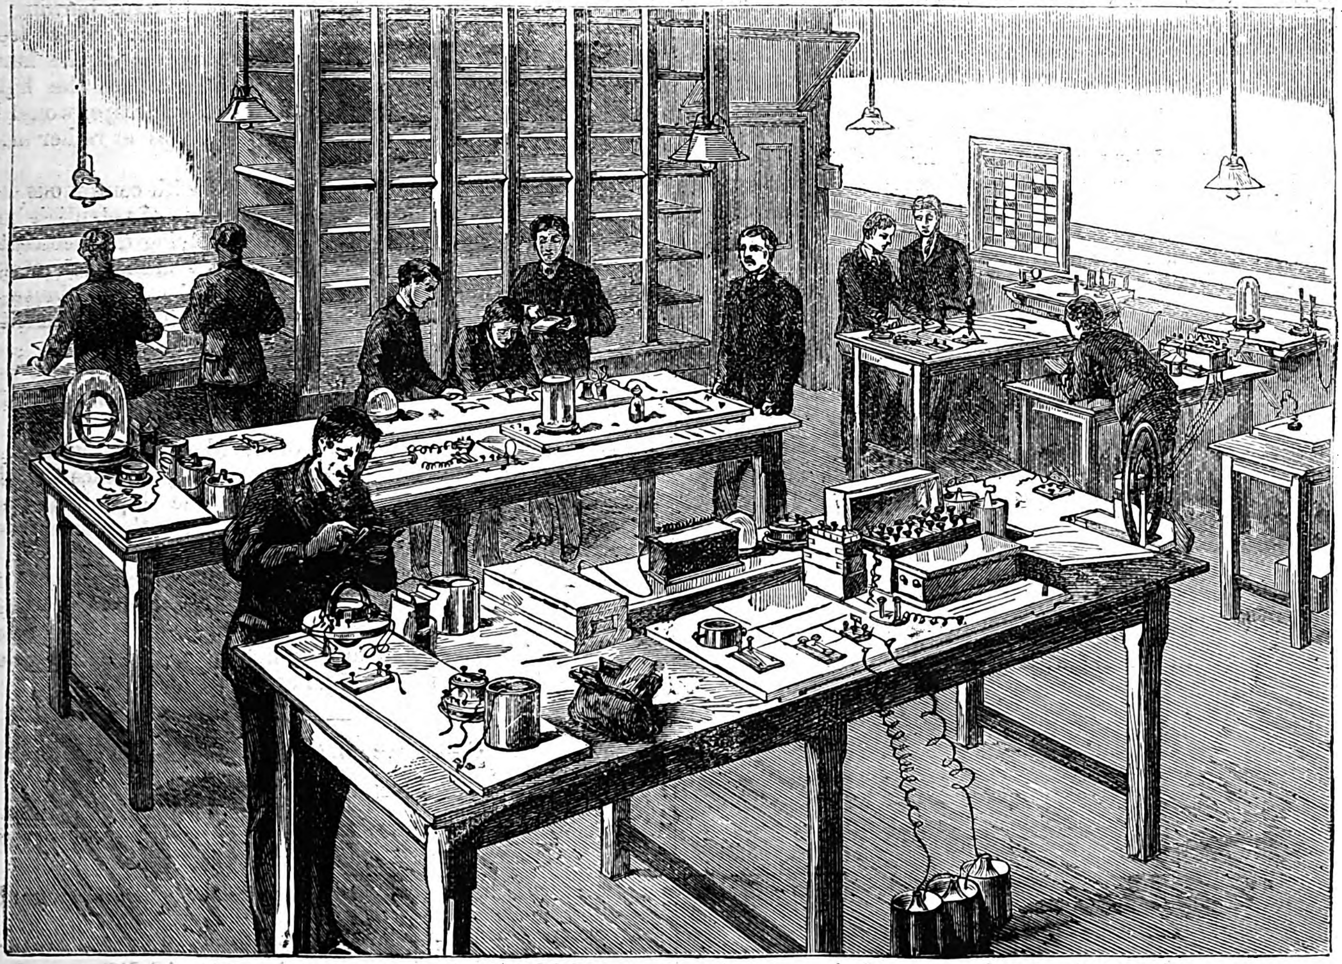
Digitized by Google

Bill; and to that end we unhesitatingly recommend our clients to move, leaving of course intact such regulations as may be necessary for the safety of the public and the rights of municipal authorities. It is not to be expected that Electric Lighting undertakers will carry on a purely experimental game for the benefit of the public; nor do the public expect it of them. Let, therefore, the advantages of the electric light be preached far and wide; but let it be known at the same time that the prohibitory enactments of the Electric Lighting Act alone prevent the general spread of those advantages.

FINSBURY TECHNICAL COLLEGE.

In a note in last week's issue we referred to a pamphlet describing the work of the City and Guilds Institute, which had been written for the opening of the Central Institution, in Kensington, an event which we also recorded in the same note. We ascribed to Prof. Ayrton the authorship of this pamphlet, but find that it was written by Mr. Philip Magnus. We now give an extract from this little compilation, which details the work done at the Technical College, Finsbury, E.C., and at the same time publish an illustration of one of the laboratories at that college, which we think will interest our readers.

Less than two years after the foundation stone was laid, the new college in Tabernacle-row was opened. The building was erected by Messrs. Peto Brothers, from designs furnished by the architect, Mr. E. N. Clifton, under whose direction it was completed. Including the expense of fitting and furnishing the laboratories and workshops, the building has cost over £35,000, towards which sum the Drapers' Company contributed £10,000. The structure is very simple, without ornamentation of any kind. It consists of three stories besides the basement. On the ground floor to the left of the entrance are two rooms belonging to the Physical Department, under the direction of Professor Ayrton, used for delicate measuring experiments in telegraphy, &c. In the rear, looking into the playground of the Cowper-street schools, is a large room used for brewing and for experiments requiring the use of steam in organic chemistry; and adjoining this room is a physical laboratory, for experiments in heat. A small class room for general purposes, and a workshop for the preparation of physical instruments are on the same floor. The staircase is in the centre of the building, and lighted from the top, and is surrounded on all sides by class rooms and laboratories. On the first floor are two lecture rooms, each capable of accommodating 200 students—one being used mainly for lectures in chemistry, and the other for lectures in physics and mechanics.



Finsbury Technical College. One of the Laboratories for First Year's Electrical Engineering Students.*

The physical lecture room communicates with a large and lofty museum of physical apparatus, and adjoining this are two other laboratories. These rooms are arranged for the carrying on of an organised series of experiments in current and in statical electricity. The peculiarity of the method adopted is that each experiment has all the apparatus required for performing it ready in position, together with printed instructions. The students work in groups of three, as shown in the engraving. The instruments needed for each experiment are mounted on a board, which can be taken to the lecture room for use during the lecture. Examples of such arrangements of apparatus are now on view in the exhibition. Adjoining these rooms is a small apartment fitted up with drawing tables, in which the students plot out curves, and record the results of their experiments on squared paper. The second floor is

* We are indebted to Mr. Magnus for the oan of this illustration.

Digitized by Google

mainly occupied by the chemical laboratories. The main laboratory has ninety-six working places, each of which has two drawers and two cupboards, and is available for two students working at different times. Each bench is covered with a hood, at the top of which are openings at intervals connected with the chimney, in which a draft is produced by the waste heat from the boilers, the flues passing down the benches and along the floor. The laboratory is divided by double glass screens, between which are the arrangements for the supply of sulphuretted hydrogen for the use of students. Plans of the laboratory fittings are exhibited in the corridors of the second floor of the Central Institution. Besides the professors' and assistants' rooms, there is a class room, a balance room, two store rooms, and a laboratory for advanced students on the same floor. The instruction, which is under the direction of Professor Armstrong, and will remain under his charge until the opening of the Central Institution in January next, is somewhat different from that of most chemical schools, the object in view being to teach the main facts and principles of chemistry, and to lead the students to observe correctly, and to reason from experiment, rather than to make them highly proficient analysts. Indeed, the teaching of analysis as in ordinary schools is a very unimportant feature in the earlier part of the course.

In the basement of the building is a large room which contains dynamo machines, worked either by the main steam engine or by the gas engine in the same room. The greater part of the building is lighted by incandescent lamps, which are supplied with a current from an Edison dynamo machine in this room. Another room in the basement is fitted up as a mechanical laboratory, under the direction of Professor Perry, who at present has charge of the instruction in engineering and in mathematics. The apparatus in this laboratory is nearly all of a novel kind. Among other experiments are those on the energy of a rotating body, the resistance of wire to extension and torsion, and of beams loaded and supported in various ways, and of the vibration of the pendulum, &c. Some of the apparatus used in these experiments, portions of which have been made in the school itself, are now on view in the Central Institution. Adjoining this laboratory are two workshops—one fitted with benches and lathes for woodwork, and the other with vices and machine tools. These workshops are in charge of a practical mechanic, and the students are able to construct models and machines for their own use and for the use of the college. There is also an engine room containing a boiler and steam engine, which are provided with appliances for measuring evaporation, steam temperatures, steam pres-

CITY AND GUILDS OF LONDON INSTITUTE.

The following questions were set at the recent examinations for students who wished to pass in the Honours Grade. The Ordinary Grade papers 22 B and 22 C will be found in last week's issue :—

PAPER 22 B.—*Electric Lighting and Transmission of Power.*

HONOURS GRADE.

[*Candidates are not to answer more than one out of the first three questions, and not more than seven altogether.*]

Questions 1, 2, and 3 are the same as in the ordinary grade paper.

4. A, B, and C are three points, each at a distance of 157 yards from the next; at A there is a dynamo; at B a group of 200 incandescent lamps requiring 110 volts and 0·75 ampere each; and at C a group of 250 lamps requiring 100 volts and 0·83 ampere each. Calculate the diameter of the copper conductor that must be used for the going and return wires between A and B and between B and C respectively if the potential difference maintained at the terminals of the dynamo is 112 volts. One yard of commercial copper wire one square inch in section has ·00002435 ohm resistance.

5. Show that when a number of houses are supplied with electricity in *series* it is possible to make the supply of electric energy given to any one house *absolutely constant* and independent of the amount consumed by the other houses. Describe, with drawings, the simplest method that could be practically adopted for fulfilling this object if there be no special restriction as to the potential of the main at any point.

Show that by no known system can this result be absolutely attained if the houses be supplied with electricity in *parallel*. Give, however, the details, and illustrate by drawings the method you would adopt for making the supply to each of the houses in parallel as nearly as possible independent of the consumption on the rest of the circuit.

6. Describe in detail the various systems that have been devised for *economically* supplying electric energy to a large district of houses without the potential in any one house being made to exceed that of the earth by, say, 150 volts. Which of these systems would you practically adopt, and why?

7. Explain fully what are the various causes of loss of power in an electro-motor, and how each kind of loss may be practically diminished.

8. Explain why the efficiency of an incandescent lamp is increased by sending a large current through it, while its life is diminished. The life of good incandescent lamps burning at their normal power is said to be 1,000 hours. Show from your own experience whether the *economical use* of the lamp, taking into account energy consumed to produce the light, together witth the cost of renewals of broken lamps, would be increased or diminished by burning the lamps at rather more than their normal candle-power.

9. An electric railway is to be worked with continuous currents. Give a table showing what difference of potentials you would allow between the conductors supplying the electricity, taking into account the number of segments on the commutator of the dynamo and the number of revolutions per minute of the armature, so that the conductors supplying the electricity, if touched by passers by, should not be dangerous.

10. Explain in detail the experiments you would carry out to determine the efficiency of a dynamo and the efficiency of a motor.

11. A dynamo is to be placed on board ship. What type of dynamo would you select, and how would you place it relatively to the ship so that the rolling of the ship should produce least strain on the bearings of the rotating armature? Give full reasons for your answer.

12. Explain why an electric light is less penetrating in foggy weather than a gas light of the same intensity. What methods would you adopt for making the electric light more penetrating? What standard of light would you use when measuring the illumination of an arc lamp, and why?

22 C.—*Electrical Instrument Making.*

HONOURS GRADE.

[*Candidates are not to answer more than one out of the first three questions, and not more than seven altogether.*]

Questions 1, 2, and 3 are the same as in the ordinary grade paper.

4. Explain why change of temperature alters the constant of an instrument used for measuring potential difference, but does not affect the readings of an instrument used for measuring current. How may the error in the former instrument, arising from the change of temperature from day to day, be automatically entirely compensated for? Will such a method of compensation compensate for the error arising from the heating of the coils by the passage of the current?

5. In making a galvanometer for measuring potential difference, consider whether it is better to put all the resistance on the bobbin or to wind the galvanometer with a lower resistance and employ an auxiliary resistance coil. Of what material would you make the wire wound on the galvanometer bobbin so that the error arising from the heating of the bobbin by the passage of the current should be a minimum?

6. Calculate the weight, length, and resistance, at 15°C., of a copper wire one-tenth inch thick, and having 95 per cent. conductivity used in coiling an electro-magnet, the dimensions

Digitized by Google

of which are:—Distance between end cheeks 15in., external diameter 5in., and internal diameter 3in. Specific gravity of copper 8·9. Weight of a cubic foot of water 62·4lb. Resistance, at 0°C., of one foot of pure copper wire $\frac{1}{1000}$ of an inch in diameter 9·718 ohms, and change of resistance per degree centigrade 0·388 per cent.

7. When the external dimensions of the bobbin of an electromagnet are fixed, prove what should be the diameter of the iron core compared with that of the bobbin—first, for weak currents; second, for strong currents. Prove also that the same proportion of diameter of bobbin to diameter of iron core does not hold when it is the diameter of the core that is fixed, and that of the bobbin variable.

8. What is the rule for determining the best resistance of wire to wind on a galvanometer to be used with a Wheatstone bridge? Apply it to the case where the proportional coils are 100 and 1,000 respectively, the third known coil 7,500 and the unknown consequently about 750. Does it follow that a galvanometer having the resistance which you have just calculated must necessarily be more sensitive for the particular resistances on the bridge above stated than any other kind of galvanometer having a totally different resistance?

9. You are desired to ascertain the value of the deflection of a galvanometer absolutely in amperes. Describe in detail the method you would adopt, and the exact precautions you would employ to secure accuracy in your result.

10. Describe fully in detail the best method of adjusting resistance coils of low resistance. Give a drawing of a good *sliding* contact to be used with resistance coils. Describe the principle and the construction of Thomson and Varley's double sliding resistance coils.

11. What is an "artificial submarine cable?" How exactly is it made, adjusted, and tested, and what is its use?

12. Describe fully the fitting-up of a telephone exchange, giving drawings of the details.

PRIMARY BATTERIES FOR ELECTRIC LIGHTING.*

BY ISAAC PROBERT.

(CONCLUDED FROM PAGE 163.)

Let us examine the point last referred to a little in detail. Both in a voltaic battery and in a dynamo-electric machine the electric energy is ultimately referable to combustion, or, more strictly, to chemical combination. In each there is a combustible substance, oxygen or an equivalent substance, to sustain the combustion, and the means wherewith to collect and utilise the energy liberated. In a voltaic battery, the combustible substance is usually zinc, and the oxygenous substance sulphuric acid. In a dynamo-electric machine—or rather in the furnace of the engine that drives it—the combustible substance is coal, and the oxygenous substance air. The question, therefore, as ordinarily presented, resolves itself into this:—Required a certain quantity of electric energy; can it be more economically produced by burning zinc in sulphuric acid in a voltaic battery, or by burning coal in air in the furnace of the engine of a dynamo-electric machine? In answering this question, we must consider the relative cost of zinc and coal, their thermal equivalents—that is, the amounts of heat obtainable by the combustion of equal weights of the two materials; the efficiency of the battery and the engine and machine—that is, the proportion of useful work obtained to the total energy generated; the cost of the oxidant of the zinc-air, the oxidant of the coal, costing nothing; the relative cost, both original and for maintenance, of the battery and the dynamo and engine; and the relative cost of attendance. In the case of the battery there is also the possibility of the utilisation of the bye-products to be considered.

To make the matter quite clear let a practical illustration be taken. Let it be supposed that a house has to be lighted by a hundred incandescence lamps, each requiring a current of ·75 of an ampere urged by an electromotive force of 100 volts. The rate at which energy is expended in each lamp, expressed in volt-amperes or watts, of which 746 are equal to a horse-power, will be ·75 × 100, that is 75. The energy expended in the 100 lamps will be at the rate of 7,500 watts, which are equal to 10·05 horse-power. But this, it must be remembered, is the actual rate at which energy is expended in the lamps. The energy that has to be developed by the engine is greater, for no dynamo-electric machine is perfectly efficient, no dynamo machine gives out as electrical energy the exact equivalent of the mechanical energy expended upon it. Let it be supposed that the machine used in our installation has a "commercial efficiency" of 80 per cent.—that is, that 80 per cent. of the mechanical energy put into the machine reappears in the external or lamp circuit as electrical energy, the balance being wasted in heating the armature coils, and the friction of axles, slipping of belts, and other mechanical sources of loss. Then the rate at which energy is generated by the steam engine must be 10·05 × 1·25, that is 12·55 horse-power. This mechanical energy is to be produced by the combustion of coal, and if all the heat liberated in the combustion of the coal could be collected and utilised, the supply of coal required to generate energy at the rate of 12·55 horse-power would be very small; but, unfortunately, steam engines, even of the best make, have but low efficiency, and a horse-power hour of energy requires in practice somewhere about 4½ lbs. of coal for its production; 12·55 horse-power-hours will therefore require about 56½ lbs. of coal—say, roughly, half a hundredweight, the cost of which is not more than 6d. Assuming that the lamps were required to burn for 1,800 hours a year—that is, on an average, nearly five hours a day—the annual cost for coal would be £45. The prime cost of a suitable dynamo machine and engine (with boiler) would be, say, £300, the interest on which, at 4 per cent., would be £12, and the annual depreciation, at 10 per cent., £30; the cost of attendance would be about £60, so that the prime cost would be £300, and the total annual cost £147, or £1 9s. 5d. per lamp.

If a galvanic battery is used to supply the current to the lamps, the energy will require to be produced at a rate of somewhere between 10·05 and 20·1 horse-power, for the efficiency of a galvanic battery depends upon the relation subsisting between the resistance of the battery itself and the resistance of the external circuit. When the greater resistance is reduced until it exactly equals the smaller, the greatest possible current is obtained from the battery, but exactly one-half of the energy liberated is wasted in heating the battery. When the external resistance is high, as compared with the internal, the current is less, but the percentage loss of energy is also less. As a matter of practice, therefore, it becomes advisable to arrange the resistances so that the external is greater than the internal, whereby the efficiency of the battery is made to as nearly approach a hundred per cent. as we wish. Let it be supposed that in our installation the efficiency is, as in the dynamo just considered, 80 per cent. To liberate a horse-power-hour of energy, a quantity of zinc must be oxidised equal to 2·022 lbs. divided by the electromotive force of the galvanic couple in use. It is calculable that the highest electromotive force obtainable in any zinc sulphuric acid battery is 2·248 volts, from which, however, a deduction must be made on account of the energy absorbed in the chemical action of depolarisation. The amount of the deduction will depend upon the nature of the depolariser. With nitrate of soda and sulphuric acid it is ·708 volt, with bichromate of potash it is ·343 volt, and with fuming nitric acid ·284 volt. In order to do fullest justice to batteries, let it be assumed that strong nitric acid is the depolariser used in our installation. The deduction to be made from the total electromotive force of the battery is therefore ·284 volt, and the net electromotive of the battery is 1·964 volt, which corresponds to a consumption of 1·03 lb. of zinc per horse-power-hour of energy. To liberate 12·55 horse-power-hours, 12·93 lbs.—say 13 lbs.—of zinc must be used. If the price of zinc be taken at 2½d. per lb., the zinc used per hour costs 2s. 8¼d. But the expense does not end here. Air, the oxidant of coal, costs nothing; whereas sulphuric acid, the usual oxidant of zinc, is of considerable value, costing, even on the commercial scale, ¾d. per lb.

To oxidise a pound of zinc 1½ lb. of sulphuric acid is required, as is shown by the equation, $Zn + H_2SO_4 = ZnSO_4$

---

* Paper read before the Society of Arts, May 28, 1884.

Digitized by Google

$+ H_2$. To oxidise 13 lbs. of zinc, 19½ lbs. of acid are therefore required, which costs 1s. 2⅝d.; this added to the cost of the zinc, makes about 3s. 11d. But we cannot stop even here. In order that the zinc may give the greatest possible return of energy, the electromotive force of the voltaic arrangement must, as has been stated, be high, and this—as a net result, at least—can only be obtained by the aid of a good depolarising liquid. We assumed ourselves to be using strong nitric acid, and if we suppose that the average effect of nascent hydrogen upon this substance is to produce nitric oxide (N_2O_2), the amount of acid required will be shown by the equation, $2HNO_3 + 3H_2$ (equivalent to 3Zn) $= N_2O_2 + 4H_2O$. It follows, therefore, that the solution of every pound of zinc is accompanied by the deoxidation of ⅔ lb. of nitric acid. In the production of 12·55 horse-power-hours of energy, 8⅔ lbs. of nitric acid will therefore be deoxidised, the cost of which, at 6d. per lb., is 4s. 4d. This, added to the cost of zinc and sulphuric acid, gives 8s. 3d. as the total cost of materials.

But we have not yet done. A battery cannot be charged, and then kept in action until every grain of zinc and every drop of acid have been consumed. It has been found by experience that no more than about 20 per cent. of the acid can be utilised. When this proportion has been used, the battery begins to flag, and is soon of no further use for electric lighting until the solution has been changed. The greater part of the acid is thus removed as spent solution. But neglecting this source of waste for the moment, and assuming that by a careful process of "refreshing," it is possible to completely exhaust the acid solution, let us see what the cost of our 10·05 horse-power is when generated by a galvanic battery. We have seen that the cost of materials per hour is 8s. 3d., and assuming, as before, that the light will be required for 1,800 hours a year, the annual cost for materials only is £742 10s. 0d. The prime cost of the battery may be taken at £120, the interest, at 4 per cent., on which is, say, £5, and the annual depreciation at 10 per cent. is £12. The cost of attendance is very difficult to determine. Primary batteries have as yet been used for electric lighting to such a small extent that there are, practically, no records of experience whereon to base an opinion. It is claimed by the inventors of batteries that the cost is very small; they say that no skilled attendance is required, and this seems reasonable; and that there is nothing further to do than might be done by a domestic servant in the ordinary course of his duties. Let us assume that this is so, and that the cost of attendance is so small as to be negligible.

If we divide the total annual cost (that is £759 10s.) by the number of lamps, the annual cost per lamp is found to be £7 11s. 8d., as against £1 9s. 5d., when a dynamo machine is used. The difference is great, but it becomes even greater when we remember that it is never possible to completely use the acid solution.

From what has been said, it will be gathered that, in a comparatively large installation such as has been sketched, primary batteries have little chance of success; but for smaller installations of, say, ten to twenty lamps, there may, perhaps, be a field of action open to them. Few people occupying a house requiring so few lamps as this would incur the trouble of a dynamo and engine, although for health's sake they might not object to the cost of the light as produced by a battery.

In what way is it possible to reduce the cost of electric lighting by galvanic batteries? It is evident that there are four ways open; and invention has been active in all. In the first place, a cheaper oxidisable substance than zinc may be employed; and in the second, possibly a cheaper oxidant than sulphuric acid. Next, contrivances may be adopted by which the solutions are more completely exhausted; and lastly, the bye-products—the substances formed during the action of the battery—may be utilised in the arts.

In the first place, as to the oxidisable substance:—Zinc is almost universally employed, but lead and iron have been suggested, and a battery using the latter substance is now before the public.

Next, as to the oxidant, or speaking more generally, the solvent of the positive element of the cell:—Sulphuric acid has been replaced, among other substances, by hydrochloric acid, and a battery employing this liquid has been introduced by Mr. Ross.

As to the bye-products, little can be said, except that the less said the better. Some promoters of patent batteries make a great point of the value of the bye-products of their batteries, but, as a matter of fact, their statements on this point will seldom bear investigation. A zinc residue contains a certain percentage of the metal in a state of chemical combination, from which it has to be recovered by a somewhat costly process, and one hardly likely to afford any profit to the person using the battery.

It may be interesting to notice that, in the Telegraph Department of the Post Office, no residues are thought worth preserving, except the "black mud" (technically so-called) from the Daniell cells, which contains a very large percentage of pure copper in the metallic state. Last year there were 69,323 Daniell cells in use, and the sum realised by the sale of the year's "black mud" was £167 14s., or rather more than a halfpenny per cell per year. An idea may be formed from these figures of the magnitude of the sum likely to result from the sale of the zinc residues—which in the Post Office are thrown away as worthless—in the case of an ordinary householder using some ten or twenty cells.

During the past few years, several batteries especially designed for use in electric lighting have been devised, and the inventors of the more important have been good enough to bring their batteries here to-night, or to furnish descriptions of them. These batteries may be divided into two classes; those in which the liquids are kept in motion, and those in which they are allowed to remain in a state of quiesence. Of the latter, one of the most important is that devised by Messrs. Holmes and Burke. A description which these gentlemen have been good enough to furnish reads thus:—

"Each battery of eight cells can be charged or discharged at two operations, by means of a system of syphons formed partly in the substance of the outside cells. In order to charge the battery it is only necessary to fill a wooden measuring vessel with the exact quantity of fluid necessary to run into the battery, to connect this vessel with the long leg of one of the syphon systems, and to raise the vessel to a certain height, when the liquid immediately distributes itself amongst the cells, and is bound to attain a uniform height in each of them. To discharge the battery, it is only necessary to reverse the process.

"The fumes are collected and suppressed. The porous pots are sealed into wooden covers, which contain passages for the escape of fumes. The passages communicate with one main pipe formed in the substance of the cells, and the fumes can thence be led away to the fume box, where they are either dissolved, or chemically absorbed, according to circumstances.

"The connections between the cells are so simple that they never can be coupled up wrongly, and they are placed beyond the reach of injury by acids or fumes. They never require disconnection when the battery is discharged or re-charged. They require partial disconnection when the plates have to be amalgamated, but the latter, when once thoroughly amalgamated, hardly ever require re-touching. Plates have been run for two months without re-amalgamation.

"The depolarising liquid is cheap and easily handled. It is made of nitrate of soda dissolved in solution of sulphuric acid of a particular strength. It depends for its action on the formation by the current of nitric acid in the porous pot. The hydrogen entering decomposes the nitrate of soda by the aid of the acid, forming sulphate of soda and nitric acid. The liquid is of good conductivity, and as the nitric acid is only formed as it is wanted, the inconvenience of handling this very disagreeable acid is avoided.

"The cost of the liquid is only 5½d. to 6d. a gallon. Each gallon furnishes from 750 to 800 ampere-hours of electricity at an electromotive force of 1·92 volt—*i.e.*, about 1,536 watts, or very nearly two hour horse-power.

"The internal resistance of the battery is very low for a primary cell, and equals ·02 ohm as nearly as possible."

It may be added that, like the generality of electric lighting

Digitized by Google

batteries, the batteries of Messrs. Holmes and Burke employ carbon and zinc as the elements.

The battery which next claims attention is that of Mr. O. C. D. Ross, of which a model is on the table. The chief point of novelty distinguishing it is the ingenious arrangement for charging and discharging the depolarising liquid.

The battery itself is enclosed in a box, about 1 ft. square by 7 ft. long, which contains thirteen double cells, the plates in each of which weigh about 10 lbs.; the whole box when charged weighs about 2 cwt. Each cell contains two carbon plates (formed of ½-in. carbon rods placed side by side), which are immersed in dilute hydrochloric acid mixed with one-sixth of its bulk of a mysterious compound called by Mr. Ross "Eureka," but which might doubtless be replaced, without materially affecting the action or the cost of the battery, by nitric acid. The zinc plates dip into a solution of common salt, the liquids being kept apart by porous partitions. The mechanical arrangement by which the carbon cells are filled and emptied is very simple; a horizontal pipe connected by flexible tubes to the bottom of each inner cell is raised or lowered; one end is attached by a flexible tube to a cask of acid, and the other end is led to a waste tank. When the horizontal pipe is raised, and communication with the waste tank cut off, the acid flows, on turning the tap of the acid cask, into the inner cells. When spent liquid is required to be removed, the horizontal pipe is lowered, and the liquid flows from the cells to the waste tank. The outer cells are filled with a solution of salt in one operation, by pouring the solution into a groove extending the whole length of the box, and connected by side passages with the cells.

The Ross battery has been examined by Dr. Hopkinson, who reports that:—

"Comparing this battery with others, a great deal may be said in its favour.

"Its constancy with a large current is remarkably good.

"The liquids used in the cells are less expensive than in any battery having any pretence to constancy.

"Mr. Ross's method of drawing off and replenishing the liquid is very convenient."

The electromotive force per cell is stated to be 1·82 volt, and the resistance 0·06 ohm.

Another battery, introduced some time back, is that known as the "Edco" or "Heap" battery. It is a carbon-zinc couple using bichromate of potash as the depolariser, and dilute sulphuric acid as the excitant. The cells are lined with lead, and hold each 1½ gallon of the bichromate mixture (which can be purchased ready prepared at 1s. per gallon). The zinc plates are 10 by 6 inches, and so offer a total surface of 120 square inches to the action of the acid; they weigh 3 lbs. each. The electromotive force is stated to be 2 volts per cell, and the resistance 0·2 ohm. The point of novelty is claimed to lie in the preparation of the bichromate solution, the description of which is best given in the manufacturers' own words. They are as follow:—

"In each lead cell pour six pints of water, and in each repeat the following operation:

"Fill the colander (which is supplied with the battery) with bichromate of potash, and hang it in the cell so that the crystals are just immersed in the water. Pour about one-fourth of three pounds of sulphuric acid over the crystals in the colander slowly, stopping occasionally when the liquid boils. As fast as the bichromate of potash gets dissolved, add more, and continue pouring in sulphuric acid as before, until there are used up for each cell all of one and a-half pounds of bichromate of potash, and three pounds of sulphuric acid. When the liquid is entirely cool, it is ready for use. . . . . This fluid will last twice as long as the . . . . fluid ordinarily supplied."

Mr. Heap is good enough to exhibit a three-cell battery in action to-night.

In the other or circulating class of batteries, there is one deserving of notice. It is the invention of Messrs. Oliphant, Burr, and Gowan. It is a two-fluid bichromate battery, having zincs coated with an extremely thin film of gold before amalgamation. The exciting liquid is a solution of salts of mercury. The liquids for the outer jars and inner porous pots are pumped out of separate tanks into distinct pipes communicating with the first jar and the first porous pot. They then rise up syphon pipes into the adjoining cell, and flow onwards in this way through the whole series. To avoid any possible stoppage through friction in the pipes, it is advisable to have the first cell one-twelfth of an inch higher than the second, and so on. Thus, in a series of 36 cells, the last cell will be three inches lower than the first. The last jar and porous pot are connected to their respective tanks. The tank holding the bichromate solution is fitted as a cell, and works a Griscom or other motor, which causes two small pumps to keep the liquids in constant circulation.

D Gold Coated Zincs.

Digitized by Google

The pumps raise two cubic inches of liquid per stroke, and work at the rate of thirty strokes per minute. The pumps are constantly at work day and night, whether the battery is in use or not.

The effect of gilding the zincs before amalgamation is, it is stated, to materially decrease local action.

Many other batteries might be described, and it may be interesting to note that, during the past three years, about 150 patents for improvements in primary batteries have been applied for in Great Britain alone.

A question which presents itself in connection with the problem of economical lighting by primary batteries is this:—Is it not possible to effect economy in the lamps—to so improve the lamps that a given expenditure of energy on the part of the battery will develop more light in the lamps than is now obtained? Yes; it is possible. It would be troubling you too much to enter here into a lengthy account of the scientific principles which should guide the designer of the luminous conductors of incandescence lamps. It must suffice to say, that the ideally perfect conductor would assume a spherical form; its mass would be very small, and its surface also, and the material of which it was composed would possess the power, possessed unfortunately by no known substance, of enduring without change for an unlimited time the passage of a very powerful electric current. Of all substances hitherto used for incandescing conductors, carbon obtained by the intense heating of a pure hydro-carbon is the best. It will give a greater return in light for a given expenditure of energy, and will withstand the action of the current longer than any other substance. It becomes possible, therefore, by its aid to approach more nearly to the ideally perfect form of luminous conductor than we should otherwise be able to. If also we can so fashion the intimate structure of the carbon, that the particles already have that arrangement which they tend to assume under the action of the current, the type of perfection can be approached even more nearly. This has been done. In a patent obtained in November, 1882, by Messrs. Boulton and Soward, in conjunction with myself, a method was described by which luminous conductors can be obtained of pure deposited carbon formed under the influence of the electric current. By suitable means, these conductors can be obtained of any required degree of approximation to the theoretically perfect form. What thickness they will ultimately assume it is impossible yet to say. The shorter and finer they are made the greater is the economy, but the shorter is their life. The thickness at which the economy in action is just balanced by the increased cost of renewal of lamps is the practical working thickness, but this can only be determined by lengthy experiments, which are still in progress.

It may be noted in passing that high resistance luminous conductors—and they can be made without difficulty with a resistance of 1,000 ohms and upwards to the inch—have the great advantage that they work with a small current, although they necessarily require a somewhat high electromotive force. This enables the copper leads to be much thinner, and therefore less expensive, than in the case of a low resistance luminous conductor, worked by a large current, which is an important point worth bearing in mind.

Messrs. Woodhouse and Rawson have quite recently introduced a new lamp, which they call their "hair filament lamp." These lamps have an extremely thin, hair-like filament, whence their name. No particulars of the method of manufacturing these filaments have been published, but it appears that, like the filaments of my colleagues and myself, they are made of deposited carbon. The method of their preparation is carefully kept secret, doubtless for fear of piratical imitations, which although generally easily detected, are yet often hard to prove in a court of law. These filaments are stated to be very efficient. It is said that they will furnish a given amount of light with less then half the expenditure of energy necessary to furnish the same amount in an ordinary thick filament. This is doubtless true; the experiments of my colleagues and myself with our own filaments perfectly support this statement, and we have had the opportunity of experimenting with filaments of much greater length, and therefore light-giving power, than Messrs. Woodhouse and Rawson seem to have had, if a conclusion may be formed from the lamps before the public.

It is to be hoped that the many inventors of primary batteries who are doubtless present, will favour us with a fuller description of their inventions than the limits of this paper have permitted, and that an interesting and valuable discussion will ensue.

WILLIAM STURGEON.

Several readers have doubted the part played by William Sturgeon in the amalgamation of batteries, as mentioned in the notice of Mr. Sprague's book; others have wondered who Sturgeon was, and why he should be honoured at all. Last year the Philosophical Society of Manchester issued a work entitled "A Century of Science in Manchester," in celebration of the society's hundredth anniversary. This work was edited by the late R. Angus Smith, F.R.S., and Chapter XI. deals with Sturgeon and his claims. We reprint what is said of W. Sturgeon, leaving our readers to judge if he is not fully worthy of all the honour that can be given to a pioneer of science.

William Sturgeon, the electrician, as we may call him, or physicist, was born in Lancaster, and spent his time from 1838 to his death, December 8th, 1850, in close relations with the society, and it was here that he collected his works for publication. He was born in 1783, and as we learn from a graphic account by Dr. Joule, was reared under circumstances peculiarly suited to make a man rough, selfish, and unintellectual. To keep his father, a clever man but an idle shoemaker, poaching fish, and rearing game cocks when starving the family, was the painful work of the young Sturgeon, and to the very last he had a life of labour and poverty. The work he did was nevertheless surprising, and we give here a full list of his papers, although not done in any other case, because he was one of those men too neglected, both by the higher class of scientific men of the time and by the societies to which they belonged. It is sad to think that scientific men see no better than the public where real merit exists—surely this is nonsense, scientific men must see where science exists—well, let it be so then; they are not very well able to bring forward those who are neglected, or are they willing if able? It is to be feared that they are as other men, self being served first. It is true that at last he was seen by men of scientific eminence, and notably by our president, Mr. Binney, who, although not an electrician, was doing the work of others, and induced the Government to allow Mr. Sturgeon £50 per annum when he was old. Here also we have to make complaints. To him who hath shall be given. A sum so small would not have been offered to a man who had been fairly prosperous, but to a man who had suffered all his life this sum was to set a seal on his poverty and to continue his depression. But it is not intended to write his life. Dr. Leigh (now medical officer of health for Manchester) and Dr. Joule have written of him, and they knew him better than the writer of this did. It is enough, then, to add from their accounts the following, and first from John Leigh, F.R.C.S., &c., as it appeared in the *Manchester Examiner and Times*, December 14, 1850:—

"It was during his connection with the artillery that, as he once described to the writer of this brief notice, his attention was awakened, and his curiosity quickened, by the phenomena of a terrific thunderstorm. The whole phenomenon was a mystery to him, but he determined to become better acquainted with the wonderful agent that had so strongly excited his awe and admiration—a power that, in an instant, could rend rocks and rive trees, and yet whose visible existence was nowhere. The few books he was able to obtain afforded him little information, and even the perusal of those showed him that in education he was deficient in the elements essential to a physical investigator. With an energy and perseverance that characterised him through life, he resolved to overcome these difficulties; and he set about it in a manner that indicated the high order of his mind. He began at once the study of mathematics, of which he obtained an excellent knowledge. He then cultivated the Latin and Greek languages to a suffi-

Digitized by Google

cient extent to enable him to understand the meaning and origin of scientific terms, and coin for himself such as he needed. French, German, and Italian he studied with much assiduity that he might read the researches of the great Continental philosophers. These languages, indeed, he read with considerable facility. Thus prepared, he entered on the study of natural philosophy, of which he obtained a sound knowledge; nevertheless, the phenomena of electricity and magnetism had ever the greatest charm for him. . . It is difficult to conceive a more unfavourable social position for the formation of a scientific character than that of a private soldier, the constant and wearying routine of duty, the want of privacy, the difficulty at the time of which we write of obtaining a fit supply of books, and the incessant temptations offered by companionship and a soldier's habits; and yet, surrounded by such difficulties, exposed to such temptations, and in such a position did Mr. Sturgeon master the numerous branches of knowledge, the possession of which gave to his researches and their exposition a clearness and precision that had scarcely ever been surpassed. Simple-minded and clear himself, imbued with an ardent love of truth, he had an utter abhorrence of scientific quackery, and never failed to express his contempt for those who substituted a pretended knowledge for its reality. He was exceedingly happy in devising experiments, and contriving the necessary apparatus—as may be seen by referring to Dr. Francis' 'Dictionary of Scientific Instruments'—and quick in perceiving the relations of the facts which he educed; and though it may be said that he never succeeded in the enunciation of a great law, yet no man has contributed to science a greater number of isolated discoveries of equal value and importance, or left behind him a greater number of instruments for others to work with. Some conception of his great labours and numerous contributions to science may be formed from the subjoined list of his papers:—

"1. 'An improved method of exhibiting M. Ampère's rotating electro-magnetic cylinders, by employing a horseshoe magnet instead of a bar magnet, as previously used.'—*Phil. Mag.*, September, 1823.

"2. 'On new electro-magnetic experiments.'—*Phil. Mag.*, February, 1824.

"3. 'Electro and thermo-magnetic experiments.'—*Phil. Mag.*, April, 1824.

"4. 'Description of a rotatory thermo-magnetic apparatus.' *Phil. Mag.*, April, 1824.

"5. 'On electro-magnetism.'—*Phil. Mag.*, October, 1824.

"6. 'On a new mode of showing the action which a magnet exercises on metallic discs, and on a novel phenomenon discovered thereby.'—*Edinburgh Phil. Jour.*, and *London Phil. Mag.*, August, 1825.

"7. 'Description of a complete set of improved electro-magnetic apparatus.'—*Trans. Soc. Arts* for 1825.

"8. 'On the ignition of gunpowder by the electric discharge, and on the transmission of electricity through water.'—*Phil. Mag.*, June, 1826.

"9. 'On the inflammation of gunpowder and other substances by electricity, with a proposal to employ the term momentum as expressive of a certain condition of the electric fluid.'

"10. 'Recent experimental researches in electro-magnetism and galvanism.'—Published by Mr. Sturgeon, in 1830.

"11. 'An account of an aurora borealis observed at Woolwich on the night of January 7, 1831.'—*Phil. Mag.*, 1831.

"12. 'On thermo-magnetism of homogeneous bodies.'—*Phil. Mag.* for July and August, 1831.

"13. 'On electro-magnets.'—*Phil. Mag.*, 1832.

"14. 'On the distribution and retention of magnetic-polarity in metallic bodies.'—*Phil. Mag.*, April and May, 1832.

"15. 'On the distribution of magnetic polarity in metallic bodies.'—*Phil. Mag.*, 1832.

"16. 'On the theory of magnetic electricity.'—*Phil. Mag.*, 1832, and *Annals of Electricity*, Vol. I.

"17. 'Description of an aurora borealis seen at Woolwich on the evening of December 22, 1834.'—*Phil. Mag.*, Jan., 1835.

"18. 'Description of a thunderstorm, as observed at Woolwich on June 14, 1834, with some observations on the cause of the deflection of the electric clouds by high lands, and an account of a peculiar phenomenon exhibited by means of a kite elevated during the storms.'—*Phil. Mag.*, December, 1834.

"19. 'Researches in electro-dynamics, experimental and theoretical.'—*Annals of Electricity, Magnetism, and Chemistry*, Vols. II. and V.

"20. 'On electro-pulsations and electro-momentum.'—*Phil. Mag.*, August, 1836. On October 1st, 1836, Mr. Sturgeon commenced a new scientific journal, called *The Annals of Electricity, Magnetism, and Chemistry*, and continued it, under his own superintendence, through ten octavo volumes.

"21. 'Description of an electro-magnetic engine for turning machinery.'—*Annals of Electricity*, &c., October, 1836.

"22. 'Description of two novel and brilliant electrical experiments, well calculated for the lecture table.'—*Annals of Electricity*, &c., January, 1837.

"23. 'An experimental investigation of the laws which govern the production of electric shocks, and other phenomena by a single pair of metals.'—*Annals of Electricity*, Vol. I.

"24. 'Application of the theory of magnetic electricity, and of the laws of electro-magnetism, to the explication of phenomena.'—*Annals of Electricity*, Vol. I.

"25. 'An inquiry into the attributes of the galvanometer, and how far its indications may be depended upon in electro-dynamic researches.'—*Annals of Electricity*, Oct., 1836.

"26. 'An experimental investigation of the influence of electric currents on soft iron as regards the thickness of the metal requisite to a full display of magnetic action, and how far these pieces of iron are available for practical purposes.'—*Annals of Electricity*, Oct. 1837.

"27. 'Experimental and theoretical researches in electricity.' Read before the London Electrical Society, Dec. 5, 1837.

"28. 'An investigation of the causes of the fracture of glass during an electric discharge, and on the mode of protecting it.' Read before the London Electrical Society, January 6, 1838.—*Annals of Electricity*, Vol. II.

"29. 'Researches in electro-dynamics, experimental and theoretical.'—*Annals of Electricity*, Vol. II.

"30. 'Experimental and theoretical researches in electricity.' Read before the London Electrical Society.

"31. 'Description of three different instruments for opening and shutting the battery circuit of an electro-magnetic coil machine.'—*Annals of Electricity*, Vol. III.

"32. 'Description of an aurora borealis which appeared in London on the evening of September 29, 1838.'—*Annals of Electricity*, Vol. III.

"33. 'Experimental and theoretical researches in electricity and magnetism.' Read before the London Electrical Society, December 4, 1838.

"34. 'Experimental and theoretical researches in electricity and magnetism.'—*Annals of Electricity*, Vol. IV.

"35. 'On the use of voltaic electricity in electro-gilding and silvering.'—*Annals of Electricity*, Vol. IV.

"36. 'Description of an aurora borealis observed in London.'—*Annals of Electricity*, Vol. IV.

"37. 'Description of an original cast-iron voltaic battery, and an account of some of its performances.'—*Annals of Electricity*, Vol. V.

"38. 'Experimental and theoretical researches in electricity and magnetism.'—*Annals of Electricity*, Vol. V.

"39. 'Results of galvanic experiments made on Clapham Common in autumn of 1838.'—*Annals of Electricity*, Vol. V.

"40. 'Experimental and theoretical researches in electricity and magnetism, &c.'—*Annals of Electricity*, Vol. VI.

"41. 'Examination and report of the effects of lightning on St. Michael's Church, Liverpool.'—*Annals of Electricity*, Vol. VII.

"42. 'Experimental and theoretical researches in electricity magnetism, &c.'—*Annals of Electricity*, Vol. VIII.

"43. 'Description of an aurora borealis seen at Manchester, on Wednesday, April 5, 1843.'—*Annals of Electricity*, Vol. X.

"44. 'On some peculiarities in the magnetism of ferruginous bodies.'—*Manchester Memoirs* for 1845.

"45. 'On a peculiar source of deterioration of the powers

Digitized by Google

of magnetic bars.'—Read before the Royal Society, May, 1845.

"46. 'On the electro-culture of farm crops.'—*Transactions* of the Highland Agricultural Society.

"47. 'An experimental investigation of the magnetic characters of simple bodies, metals, metallic alloys, and metallic salts.'—*Memoirs* of Manchester Literary and Philosophical Society, 1846.

"48. 'Three accounts of the aurora borealis, and on the formation of clouds as observed in the locality of Kirkby Lonsdale.'—*Memoirs* of Manchester Literary and Philosophical Society, Vol. VIII.

"49. 'On lightning and lightning conductors.'—March 21, 1848.

"50. 'On the peculiarities of the thunderstorm which occurred in this neighbourhood on July 18th last.'—Posthumous paper, date uncertain; Manchester Literary and Philosophical Society, read March 4, 1856.

"Mr. Sturgeon has also published two elementary treatises, one on electricity, the other on galvanism, besides some smaller works, the last of which was entitled 'Practical Instructions for the Protection of Persons and Property from the Effects of Lightning.'

"For a set of improved electro-magnetic apparatus, Mr. Sturgeon received in 1825 the large silver medal of the Society of Arts, together with thirty guineas.

"The following statement of some of his most important discoveries in a letter from the pen of the most distinguished physicist now left to us in Manchester is an admirable testimony to his great scientific merits, and cannot be read without interest:

"'My dear Sir: I have sifted Mr. Sturgeon's claims to the utmost. I have examined all the periodicals likely to throw light upon the history of electro-magnetism, and find that Mr. Sturgeon is, without doubt, the originator of the electro-magnet, as well as the author of the improved electro-magnetic machine. The electro-magnet described by Mr. Sturgeon in the *Transactions* of the Society of Arts for 1825 is the first piece of apparatus to which the name could with propriety be applied. Arago and Ampère and Davy had already, it is true, magnetised steel needles by passing currents of electricity along spirals surrounding them, but it does not appear that they observed the phenomena with iron needles, nor that they had any knowledge of the suddenness with which the polarity of soft wrought iron might be reversed by a change in the direction of the current. It appears, therefore, quite clear that to Mr. Sturgeon belongs the merit of producing the first electro-magnet constructed of soft iron, as well as that of ascertaining its peculiar and most remarkable properties. *Hence it was that M. Jacobi, of St. Petersburg, claimed for Mr. Sturgeon, in conjunction with Proessor Œrsted, the discovery of the electro-magnetic engine.* Mr. Sturgeon's claims with regard to the magneto-electrical machine appear to me to be equally well established. He was the first who devised and executed an apparatus for throwing the opposing currents into one direction, thus accomplishing for this machine exactly what Watt accomplished for the steam engine. Beside this, he is beyond dispute the author of the systems of solid brass discs and insulators going by the name of 'commutator' on the Continent and 'unitress' in America, an apparatus now universally employed in every magneto-electrical machine. Mr. Sturgeon was without doubt the constructor of the first rotary electro-magnetic engine.

"'The use of amalgamated zinc plates in the voltaic battery was originated by Mr. Sturgeon. It is an improvement of such value that it has been universally adopted ever since, although all other arrangements of equal date have been superseded.

"'Mr. Sturgeon's discoveries in the thermo-electricity and magnetism of homogeneous bodies are very important, and have placed his name higher than that of any other philosopher who, after Seebeck, has cultivated thermo-electricity.

"'The above is only a very imperfect abstract of a small part of Mr. Sturgeon's discoveries and improvements in magnetism, electricity, and the kindred sciences. Though not himself the author of extensive generalisations, he has been signally useful in preparing the way for them, and in carrying them out practically; and I know not of one individual who, under equal or even less disadvantages, has contributed so eminently to the advancement of these highly interesting and useful sciences.—(Signed) James P. Joule.'

"Soon after he left the army, Mr. Sturgeon was appointed Professor of Natural Philosophy in the Military Academy at Addiscombe, where he continued to lecture until he came down to Manchester to superintend the Victoria Gallery of Practical Science. The pressure of the times very soon necessitated the discontinuance of this institution, and Mr. Sturgeon was then unhappily deprived of any means of existence but the very precarious one arising from occasional courses of lectures. After struggling with difficulties which would have weighed many men down, he was at length, by the intercession of his friends, placed by Lord John Russell on the civil list for a pension of £50 per annum, but which he has lived a very short time only to enjoy, having but received one year and one quarter's allowance. Some time ago he resolved on collecting his numerous papers together and publishing them in one handsome quarto volume, which has been a short time before the public, and as a specimen of provincial topography has seldom been equalled.

"After tracing his career and contemplating the many valuable discoveries he gave to his country, it is painful to think that his last years were embittered by privations and pecuniary anxieties that must have preyed upon his mind and destroyed his comforts, and that at last he has left a wife and her daughter totally unprovided for.

"There is little inducement held out in this country to the cultivation of science, whilst the scientific men of other countries are ennobled, honoured, and placed in comparative affluence, as witness Professor Œrsted, a labourer in the same field with poor Sturgeon. Here they are neglected, unrewarded, and left to pine in poverty and want. The world uses their discoveries, heedless that the head that gave them moulders in the grave, the victim of its own mighty efforts, and of their ingratitude.

"In the *Athenæum* of November 23, 1850, is the following paragraph:—'At Copenhagen, Dr. Œrsted, the well-known discoverer of electro-magnetism, has been celebrating the fiftieth anniversary of his appointment at the Royal University of that city. We English are not accustomed to have our literary men spoilt as they spoil them in Denmark and some other civilised countries. All ranks contended to do the philosopher honour on this occasion. The King sent him the Grand Cross of the Order of Dannebrog. The university sent new insignia of his doctor's degree, including a gold ring, whereon a cameo bears the head of Minerva; and the citizens presented him with a beautiful villa, situated at Fredericksburg, in the outskirts of Copenhagen. King and people agree in a strange estimate of the value and status of the scientific man, according to our insular notions. We do not see how they could have improved on this sort of testimonial if he had gained a battle. Dr. Œrsted is upwards of eighty years of age.'"

Dr. Joule has viewed the matter from another point. His account of Sturgeon's discovery is of importance, establishing the scientific position of the too much forgotten discoverer.

After describing Mr. Sturgeon's improvements on the voltaic revolving machine, the result of discoveries by Œrsted, Faraday, Ampère, and Barlow, Dr. Joule says (*see* "On the Life and Writings of the late Mr. William Sturgeon," by Dr. James Prescott Joule, F.R.S., &c., *Mem. of the Lit. and Phil. Soc.*, Vol. XIV., 2nd Series, p. 59):—

"In 1824 Mr. Sturgeon began to give the fruits of his investigations to the public in the leading scientific periodical of the day. In that year no fewer than four papers of great merit appeared from his pen on the subjects of 'Electro and thermo-electricity' in the pages of the London *Phil. Mag.*

"In 1825 he published in the *Transactions* of the Society of Arts 'the description of a complete set of novel electro-magnetic apparatus.' The great merit of this apparatus consisted in the improved adaptation of the magnets, batteries, &c., to one another, by means of which Mr. Sturgeon was enabled to

Digitized by Google

perform, with a voltaic battery of the size of a pint pot, experiments which had previously required the use of a cumbrous and costly battery. The Society of Arts testified their sense of the importance of this contribution by awarding to its author their large silver medal, with a purse of thirty guineas.

"About this time Mr. Sturgeon made his great discovery of the *soft iron electro-magnet*, and having observed the high degree of polarity acquired by a straight bar of iron on making a current of electricity to circulate around it, as well as the suddenness with which the direction of polarity could be reversed by changing the direction of the current, he proceeded to construct electro-magnets on the same principle, but bent into the form of a horseshoe, so that the poles, by being brought near one another, could concentrate their action on any given object. This *soft iron electro-magnet has entered into the structure of every form of electric telegraph.*

"Passing over several highly valuable communications to the *Philosophical Magazine*, which, even at this day, would amply repay a careful study, we find him in 1830 publishing a pamphlet, entitled 'Experimental Researches in Electro-Magnetism, Galvanism, &c.,' comprising an extensive series of original experiments. In this work Mr. Sturgeon first pointed out the superior effects to be derived from the use of amalgamated plates of rolled zinc in the voltaic battery instead of the unprepared cast zinc then in general use. He prepared his plates by dipping them first into a dilute solution of acid to cleanse their surfaces, and afterwards plunging them into mercury. He showed that plates prepared in this way do not effervesce in dilute sulphuric acid, as the unprepared plates do, and in consequence require to be much less frequently renewed than the latter, whilst, at the same time, the electric current produced is much more intense and constant. It is a remarkable fact that no further improvement has been effected in the preparation of the positive plates of the galvanic apparatus, and that Mr. Sturgeon's amalgamated zinc plates are at the present day employed in every form of improved battery, whether patented or not.

"In our chronological arrangement of Mr. Sturgeon's discoveries we may next note a highly valuable paper on the Thermo-Magnetism of Homogeneous Bodies, a work the merit of which can only be duly appreciated by those who are acquainted with the extreme minuteness of the currents of which it was the object to discover the existence and direction. By a happy combination of industry and sagacity our author succeeded in proving that electric currents can be developed in any individual mass of pure metal by a mere disturbance of temperature at some particular point, and that the direction of those currents is determined by the position of the point of greatest heat and the crystalline structure of the metal, a fact of the highest importance, and which, along with others developed by him about the same time, paved the way to Dr. Faraday's celebrated discovery of magnetic electricity.

"In 1836 Mr. Sturgeon communicated a paper to the Royal Society, which contains a description of a perfectly original magnetic electrical machine,* in which a most ingenious contrivance was adopted for uniting the reciprocating electric currents developed, so as to give them one uniform direction. By this contrivance Mr. Sturgeon succeeded in producing all the effects due to ordinary voltaic currents, by means of the action of magnets on rotating coils of wire. In the same year the great industry of Mr. Sturgeon was rewarded by two other important inventions. The first of these was that of the electro-magnetic coil machine, an instrument devised for the purpose of giving a succession of electric shocks in medical treatment, and which has been generally preferred by medical men to all others intended for similar purposes. The other was an electro-magnetic engine for giving motion to machinery.

"In 1838 Mr. Sturgeon noticed a highly interesting electric calorific phenomenon, produced by a powerful battery of one hundred and sixty pairs, provided by Mr. Gassiot and Mr. Mason. On breaking the battery circuit it was observed that the disruptive discharge of electricity made the positive wire red hot, while the negative remained comparatively cool. Mr. Sturgeon applied this fact to elucidate some important points in the theory of heat.

"About this time also Mr. Sturgeon prepared a paper for the British Association for the Advancement of Science on the very important subject of *Marine Lightning Conductors*. His researches on the subject enabled him to point out the danger likely to arise from the conductors then proposed for use in the Royal Navy by Sir W. Snow Harris, by which the lightning was sought to be conveyed through the body of the ship. He propounded at the same time a new system whereby this danger might be obviated.

"In 1843, Mr. Sturgeon published a memoir in the *Transactions* of the Literary and Philosophical Society of this town, 'On the Direct Action of Caloric on Magnetic Poles, and the Displacement of Magnetic Action in Soft Iron by the Influence of Heat.' The latter part of these researches develop some curious facts respecting the total absence of magnetic action in soft iron when made red hot, and point out by what means a bar may be converted into several magnets at one and the same time.

"We notice another memoir of even greater importance in the *Proceedings* of the same body for 1846, entitled, 'An Experimental Investigation of the Magnetic Characters of Simple Metals, Metallic Alloys, and Salts.' The very extraordinary fact arrived at by this research was that *several metallic alloys become endued with magnetic properties, although the constituents separately show no such action; and that iron and nickel, two metals which, whilst pure, are susceptible of the highest magnetic powers, become almost totally inert to magnetic action when combined with some other metals.*

"The subject of atmospheric electricity was one to which Mr. Sturgeon devoted a great deal of attention from the commencement of his scientific career to within a short period of his decease. Not satisfied with the ordinary apparatus in use at the electrical observatories, he elevated exploring kites into the atmosphere, and in all seasons and weathers, and even in some instances at considerable risk to his life, did he pursue this important branch of meteorology. The result of more than *five hundred* kite observations established the important fact that the atmosphere is in serene weather uniformly positive with regard to the earth, and that the higher we ascend the more positive does it become; so that if the strata in which the kites are immersed are at altitudes corresponding to the series 1, 2, 3, 4, 5, their relative states of positive electricity would be conveniently represented by those numbers.

"Besides the above and a multitude of other researches which we have not room to notice, but which in a complete biography it would be impossible to pass in silence, Mr. Sturgeon was an ardent admirer and diligent observer of those grand and magnificent instances of the Creator's power which are exhibited alike in the lightning flash and the silent corruscations of the aurora borealis. Most graphic and highly interesting accounts of these natural phenomena appear interspersed among his more elaborate papers.

"The magnitude of Mr. Sturgeon's scientific labours would naturally lead one to imagine that his whole life was given up to original investigation. On the contrary a large portion of his time was occupied in communicating his stores of knowledge to others. For several years he filled with great credit to himself the chair of Experimental Philosophy in the Hon. East India Company's Military Seminary, Addiscombe. In 1838 he accepted the office of Superintendent of the Royal Victoria Gallery of Practical Science in this town, and subsequently to the failure of that institution, through the pressure of the times, he made strenuous though unfortunately unsuccessful efforts to establish another institution of a kindred character. As a lecturer he was distinguished by the happy facility with which he conveyed the truths of science to his hearers, and the uniform success of his experimental illustrations. Nor did he confine his efforts to mere oral enunciation. The numerous elementary treatises which he published on electricity, magnetism, and chemistry, show the desire he had to extend sound knowledge as widely as possible. At the same time he performed a real service to the cultivators of science by establishing

* This instrument is the precursor of the variety of modern dynamo-electric machines employed for the electric light, electro-plating, telegraphing, &c.

Digitized by Google

a new scientific journal, entitled *The Annals of Electricity, Magnetism and Chemistry, and Guardian of Experimental Science*, which he continued with unexampled industry and perseverance through ten octavo volumes. This work became a medium of much valuable information; and its success gave rise to a similar publication on the Continent, under the editorship of Professor de la Rive. Mr. Sturgeon's last work, which he completed only a few weeks before his death, was to collect into one large quarto volume the whole of his published papers. This work, which is got up in a first-rate style, and is illustrated by eighteen beautifully engraved plates, should be studied by all who wish to obtain a thorough knowledge of electrical science.

"In stature Mr. Sturgeon was above the average height, and his open brow and upright carriage conveyed the impression of integrity of character, an impresson which was sure to be deepened by a personal acquaintance. As a friend he was warm-hearted and generous, and always prompt in acknowledging the merit of others where merit was really due. To the widow and adopted daughter left is best known his sterling worth in the domestic circle. In politics he was a Conservative, though it will be readily believed he had no time to enter the arena of party strife. Conscientiously attached to the Church of England, he enjoyed the friendship of many of its distinguished ornaments.

"In Mr. Sturgeon we have lost a man of high moral worth and European reputation, and it may be doubted whether, with the single exception of Dalton, the Scientific Society of Manchester has ever experienced a severer calamity than by his death."

In a somewhat fuller account of Sturgeon, written by Dr. Joule, and published in the Society's *Memoirs*, Vol. XIV., 2nd Series, 1856-7, p. 78, the following specimen of his writing is given :—

"The electric fluid is so universally diffused throughout every part of nature's productions, that every particle of created matter, both animate and inanimate, which has hitherto been contemplated by the philosophers, is full of this surprising animated elemental fire.

"In regions far above the surface of the earth, where the air is much attenuated and so far thinned, near to the utmost verge of the atmosphere, as to become a conducting medium, the electric element plays its quivering streamers and sparkling corruscations in the beautiful aurora of the north. Sometimes this rare—this fascinating phenomenon—is exhibited in a steady glowing arch of light, whilst at others it expands its dancing network in transient display over the whole concave of the visible heavens.

"At altitudes less elevated than those which form the grand theatre for the display of the aurora borealis the electric discharges become more compact, and shoot slanting downwards on bright serene evenings these beautiful gleaming orbs of meteoric light which from ancient custom are still called falling stars.

"Still less elevated in the atmosphere the long black clouds swell with the electrical element in all those grand magnificent and splendid forms of lightning, with their tremendous peals of thunder, so frequently displayed in most countries during the transient rage of a majestic summer's storm.

"Descending to the earth we trace its circumfluent streams polarising this vast ball of matter, on which we are destined to live and perform all our actions, and insinuating its resistless influence in all the silent mysterious attractions of the magnet. Trace it to the laboratory of the chemist, and we find it the most active and vigorous agent in accomplishing all those astonishing changes which give new forms and new qualities to passive obedient matter.

"Besides all these important operations of nature, accomplished by the agency of electricity, it is capable of restoring the dormant muscular and nervous powers of man which have been prostrate by accident or disease, and of giving new life and new vigour to every other mode of medical treatment.

"In plants, also, as well as in animals, it is said to facilitate growth, and to give health, vigour, and heart to their general appearance.

"Indeed, so *universally* does the electric fluid appear to be employed in *most*, if not *all*, the grand processes of nature, and there is not, perhaps, a plant that grows or a limb that moves but is in some measure influenced by its powers.

"Nay, it is perhaps this astonishing, this most gigantic of physical agents, which is employed by the Great Creator to spin the earth and planets on their axes, to sweep them through the heavens in their regular periods of revolutions, and to keep in uniform motion all those massy orbs of matter which compose the countless systems of the universe.

"Brief and imperfect as is the outline which I have thus portrayed of the individual branch of science, perhaps we may venture to ask who is there, then, who knows the advantages, beauties—nay, the pleasures of scientific knowledge—who would think his time misspent, or his labours useless, in the accomplishment of so noble an acquisition?"

Dr. Joule says:—"Mr. Sturgeon was of a tall and well-built frame of body, his forehead was high, and his features were strongly marked. His address was animated, and his conversation, as it generally is when the mind is stored with knowledge, pleasing and instructive. His style of writing was at once vigorous, lucid, and graceful. In friendship he was warm and steady, in domestic life affectionate and exemplary. He had a noble mind and a generous heart. He was a close and sagacious reasoner, and an unsparing exposer of error. He detected quackery and false pretension, sought diligently for truth, and loved it for its own sake. A diligent accumulator and observer of facts, eager in the pursuit of information of whatever kind, and in communicating his stores to others, under more fortunate circumstances he would probably have left a name unsurpassed in the scientific history of his time; as it is, he will always be remembered as a distinguished cultivator of natural knowledge."

To all this we agree heartily, and feel at the same time the extreme difficulty there is in this and perhaps in any country in Europe in any man obtaining a good position in any scientific establishment unless he enters in by the colleges or universities, or has made early friendships of those who have. By their means he is put on the track of promotion, and otherwise he is often an outcast. We must feel how remarkable the influence of Sturgeon has been in developing the electrical apparatus of the present day. The results which are exciting the world are obtained by inventions begun by him, and he probably foresaw much of their value to the world.

LEGAL.

Muir and Co. v. the Anglo-American Brush Electric Light Company.

This case came before Mr. Justice Field, Mr. Justice Manisty, and Mr. Justice Lopes, in the Queen's Bench Division of the High Court of Justice, on the 26th June. We take the following report from *The Times*:—This was a very remarkable case in its history, and it also raised a curious and interesting question, which has for two years perplexed the Courts. It was remarkable, for it was an application for a fourth trial in a case which had already been three times tried, and had been repeatedly before the Divisional Courts, and once or twice in the Court of Appeal, and it raised, moreover, a very interesting question. It was an action upon a contract entered into by letters in 1882, under which the company were to take a new and peculiar machine for boring "electric generators," which would weigh about 15 tons, and of which the price was to be £736, but which the company had declined to receive, upon the ground that it was delivered too late, not having been completed until after a lapse of nine months. The dispute had been as to the time within which the machine was to be completed, the company wishing to have it in a certain time, and as the plaintiffs, the makers, had agreed to "do their best to complete it as nearly as they could" within that time, the question which had arisen, and which had sorely perplexed both judges and juries, was what those terms really meant, and within what time the machine was to be completed. The company had desired it to be delivered in eight or nine weeks. The plaintiffs replied that it was quite impossible to do it in less than 13 or 14 weeks. Afterwards the plaintiffs wrote that they would do their best to deliver the machine as nearly as possible "in eight or nine weeks," and the great question in the case which had puzzled the Courts and perplexed the Court of Appeal was what those words meant. In point of fact the machine was not completed until eight or nine months afterwards, during which period, however, until just at the end of it, the company never applied for it, and the plaintiffs, finding it not pressed for, did not use extra endeavours to complete it, and the

Digitized by Google

machine being very large and complicated, it took a great deal of care and labour to finish it, and the plaintiffs gave much evidence as to this—that the machine comprised 1,840 distinct parts, that as many men as could be were employed upon it, and there was no unavoidable delay about it Moreover, it cost £150 more in making than had been estimated; that they had "done their best" to finish it as soon as possible, and that nine months was a reasonable time for making it, though they admitted that if the contract had been to finish it in a specified time they would have put extra men upon it, and kept them at work extra hours. On the other side, there was evidence that the machine could have been finished in three months. On the whole of the evidence the jury at the first trial before Mr. Justice Pearson at Manchester found in favour of the plaintiffs. That verdict, however, was set aside on the ground that the judge had not adequately directed the attention of the jury to all the letters which had passed between the parties. Then there was a second trial before Mr. Justice Butt and a special jury at Manchester, when the jury could not agree, and the learned judge then took the matter into his own hands and directed a verdict for the company. This, however, a Divisional Court had thought was wrong, the question being for the jury, and on an appeal the Court of Appeal took the same view, and directed the case to be tried a third time. It had accordingly been tried a third time before Mr. Justice Day and a special jury at Manchester, and, after full evidence—some of it skilled and scientific—on both sides, the learned Judge left the question to the jury, with a summing up rather in favour of the company, but the jury found for the plaintiffs for £750. This was an application on the part of the company—the defendants—for a new trial on the ground that the verdict was against the evidence.

Mr. Henn Collins, Q.C. (with Mr. Gully, Q.C.), appeared for the defendants; Mr. Ambrose, Q.C., and Mr. Bigham, Q.C., were for the plaintiffs in support of the verdict in their favour.

As soon as the case was opened,

The COURT asked what the words in the contract as to time were to be taken to mean. Counsel answered that this was the question which had puzzled the Courts and even perplexed the Court of Appeal, which had tried to settle it, but had not, perhaps, succeeded in so doing. In effect the Court had held that it meant this—that the plaintiffs were bound to do their best to deliver the machine within the period fixed, which they said meant more than to do it in a reasonable time, regar l being had to the nature of the machine and the time required to construct it. [Mr. Justice FIELD said the case had been tried three times, and twice with a verdict for the plaintiffs, and now the defendants desired it to be sent to a fourth trial.] After a certain number of trials the Court can enter the verdict as they think fit. [Mr. Justice LOPES: That would be contrary to the decision of the Court of Appeal in this very case—that it is a question for the jury.] [Mr. Justice FIELD said there were cases in which verdicts of juries had been set aside again and again when wrong.]

The learned Judges here conferred together, and

Mr. Justice FIELD said would it not be better that, to avoid a fourth trial of the case, the parties should try to settle it? The machine was made, and must be worth something.

Counsel answered that the machine was now obsolete, having been superseded by others, and it was now only worth the price of waste iron. Besides, the costs were now so serious that they were larger than the price of the machine. The parties had tried again and again to settle it and had failed.

Mr. Justice FIELD said it was sad to think of a case already tried three times being tried again.

Counsel said they feared it could not be settled, and so the case proceeded. The counsel for the company offered an affidavit that two of the jury had stated that they had given their verdict on a certain ground, but the Court refused to receive it, and the case was argued on the evidence, on which the counsel for the company contended that the plaintiffs had "not done their best" to finish the machine within the eight or nine weeks.

Mr. Justice FIELD, however, asked what "doing their best" meant? Did it mean putting 500 or 5,000 men on the work, if necessary, to finish it in the time mentioned? Surely it could not mean that—to which the counsel for the company assented; but said it was for the jury.

Mr. Justice FIELD observed, upon this, that the jury had found in favour of the plaintiffs, and how was the Court to determine the question?

After hearing counsel on both sides at considerable length, and fully considering the case,

The COURT came to the conclusion that they ought not to set aside this verdict. The Courts, they said, were bound to pay due respect to the verdicts of juries, and it was for the party who desired to set aside a verdict as against evidence to make it out very clearly that it was against the evidence. This was peculiarly so in a case such as the present, which turned on matters of business, and the question was peculiarly for a jury. The machine to be made was of a very difficult and peculiar character, and engineers of the highest reputation had given it as their opinion that the time taken in making it was, under all the circumstances, very reasonable. No doubt the time of completing it was material on both sides, and considering the difficulty of making it, which the plaintiffs had pointed out, they at first said they could not undertake to make it in less than thirteen or fourteen weeks. That, however, was not accepted, and ultimately it was agreed that the plaintiffs should "do their best" to finish it as nearly as possible in eight or nine weeks, and that raised a question for the jury which had already been three times tried, twice in favour of the plaintiff, and now the Court was asked to set that verdict aside and send the case to a fourth trial. That was extremely undesirable if it could be avoided, though they should not shrink from doing it if it were really necessary to justice. But this rendered it necessary to look closely into the grounds on which the verdict was complained of. Certainly some of these grounds were not devoid of strength, and the Court were not sure they would have found the same verdict. On *primâ facie* evidence it did seem strange that a manufacturer who had only asked three months to make the machine had taken nine months to make it. It certainly had been urged that the company for nine months had not asked for it, and that, therefore, the plaintiffs had supposed they were in no great hurry for it. That ground, however, for delay had not been made out, but on the whole evidence, and especially the delay on the part of the company, the case had been properly left to the jury, and there were no sufficient grounds for disturbing the verdict. The case now, at all events, had been fully tried by the jury on a proper direction, and as the question was for them the time had now come to put a stop to this sad litigation, and therefore the verdict must stand and this application for a new trial be dismissed with costs.

Clark v. Bennett.

In the High Court of Justice, Queen's Bench Division, on Monday last, before Mr. Justice Hawkins and a special jury, an action was brought by Captain Arthur Hamilton Clark against Mr. James Gordon Bennett, proprietor of the *New York Herald*, in which the plaintiff sought to recover £5,000 as remuneration for services alleged to have been rendered the defendant at his request. The defendant paid £859 into court as sufficient to meet all claims which the plaintiff might have against him.

The Attorney-General, Mr. E. Clarke, Q.C., and Mr. C. H. Anderson appeared for the plaintiff; and Mr. R. Webster, Q.C., and Mr. Jeune were counsel for the defendant.

The ATTORNEY-GENERAL, in opening the plaintiff's case, stated that the plaintiff was an underwriter, who at the time he was retained to carry out the work for which he now sought payment was earning about £2,000 a year. The defendant was Mr. James Gordon Bennett, a well-known American, of journalistic repute, and owner of the *New York Herald*. It appeared that about the year 1882 Mr. Bennett had reason to fear the rivalry of Mr. Jay Gould's system of telegraphic news agency, and was desirous of establishing a new cable between America and Europe over which he should have absolute command. It was with the object of promoting and carrying out this scheme that he had engaged the services of Captain Clark, the plaintiff, and it was for such services that that gentleman now sought payment. The plaintiff worked most assiduously at getting up the proposed company, the Articles of Association of which made provision that he should be paid a yearly salary of £3,000. Eventually—for what reason he did not know—Mr. Bennett had thought proper to throw over the first scheme for establishing the new cable, and had entered into fresh plans, with a similar object, with the great American capitalist, Mr. Mackay; but that was no reason why Captain Clark, the plaintiff, should not be adequately paid for all his trouble with the original scheme, and compensated for any damage which his business might have suffered by reason of his not having been able to devote all his time to it, as he would otherwise have done.

Captain Arthur Hamilton Clark, called, said that previously to August, 1882, he had known Mr. James Gordon Bennett for some years. He had carried on a business in this country as the agent to American underwriters. In August, 1882, he received a telegram containing a message from Mr. Bennett, who is the proprietor of the *New York Herald*. The telegram was put in, and was dated the 22nd of August, 1882; it was from a Mr. Longfellow, and contained a request from Mr. Bennett asking the plaintiff to go over and meet him on his yacht, the "Namouna," at Cowes. He went, and Mr. Bennett stated that, as Mr. Gould controlled the lines of the Western Union Telegraph Company, he would be compelled to form a new line; Mr. Pender and Mr. Gould, in conjunction, also controlled the Atlantic lines. Further, Mr. Bennett said that Mr. Jay Gould was buying up two or three of the principal newspapers in New York, and that he would soon be in a position to crush him (Mr. Bennett). For these reasons he proposed to lay a new cable, and he thought, perhaps, Mr. Garrett, the president of the Iowa Railway Company and a large telegraphic line proprietor, might join him. But however this might be, he wished him (the plaintiff) to act for him (the defendant) in the matter. Witness continued: Mr. Bennett then asked me what I was making in my business, and what would make it worth while my accepting his offer. I replied that I was making £2,000 a year. Mr. Bennett replied, "Oh, I would pay you £3,000 a year." He asked whether I would like to put any money into the concern. I answered that I should, but not being a capitalist it would not be much—about £3,000. He then said, "I would give you 10,000dols."—*i.e.*, about £2,000 worth of shares, to make it £5,000 in all. I remained some days on the yacht, and returned to London on the 1st September, with the object of at once setting to work to gather all the necessary information requisite to the immediate promotion of the proposed company. The witness here detailed the various scientific persons with whom he consulted, and the various particulars of his services upon which he relied to substantiate his claim, and added—On the 30th of September, 1882, I wrote a letter to Mr. Bennett relative to the matters in hand, and asked to have my real position determined. Shortly after this I had gone to Paris to see Mr. Bennett early in October. Mr. Bennett referred to my letter, and asked me if £3,000 a year salary would satisfy me. I replied that it would. He further said that he was going to give me the 10,000dols. interest in the company besides. This was his own private matter, but Mr. Garrett agreed to the salary. We also discussed cable matters, and it was arranged that I should continue my preliminary efforts in furtherance of Mr. Bennett's views, and promoting his new cable. I returned to London and worked on, and when Mr. Bennett returned from America, on the 17th of November, I met him at Queenstown, and detailed to him all I had done, and laid before him the correspondence, expert reports, and other documents

Digitized by Google

relative to the scheme. Mr. Bennett told me that he had seen Mr. Garrett in New York, and had arranged everything with him, and wished to form a company as soon as possible. Subsequently to this Articles of Association were drawn up. These contained a provision appointing me as managing director in the proposed company, at a yearly salary of £3,000. I took these over to Paris to show Mr. Bennett at his request. Mr. Bennett made no objection to that provision. These were signed in London by Mr. Bennett on the 30th of November, 1882.

Mr. Justice HAWKINS said that it appeared to him to be a case that must ultimately resolve itself into questions of detail which could much better be dealt with elsewhere.

At the suggestion of the learned Judge a consultation ensued, the result of which was that the case was referred to a gentlaman—to be named by the counsel for the plaintiff—to settle all matters,

Mr. WEBSTER, Q.C., stating that, on behalf of Mr. Bennett, he was prepared to have the question determined, not upon legal grounds, but as between gentleman and gentleman, whether the plaintiff was entitled to any advance on the sum paid into court or not.

The Corporation of Bristol v. the United Telephone Company.

On Tuesday this case came before Mr. Justice Cave in the High Court of Justice. The plaintiffs claimed the right to have some kind of control over the erection of telegraph wires within their city; and they claimed this first in the case where wires were carried over lands which were vested in them in fee; and, secondly, where wires, being carried over streets, might be a source of danger to the public. It was said that these last-named wires might come down in a high wind, a snowstorm, or in the case of a house being on fire.

The Solicitor-General, Mr. Philbrick, Q.C., and Mr. Casserley were for the plaintiffs; and Mr. Webster, Q.C., and Mr. Moulton for the defendants.

After some discussion it was admitted that the plaintiffs had absolute right of control where wires passed over their freehold land; and it was agreed that as to any other wire which was supposed to be a source of danger, that question should be decided out of court. In the end the case was adjourned *sine die* to allow time for this arrangement to be carried out.

THE INVENTORS' INSTITUTE.

On Wednesday last the members of this institute held what might be termed a field day at the Health Exhibition. The meeting was announced for two o'clock, and the members and guests then started from the jury room under the guidance of Mr. S. J. Mackie, C.E., to inspect various exhibits. Amongst other things attention was directed to the model dairies, and general satisfaction was expressed with the arrangements therein. The street of "Old London" was visited, and the various works carried on in the shops. This production, from the designs of Mr. Birch, is really one of the wonders of 1884, and attracts as much attention as any part of the exhibition. The engines of Messrs. Davey, Paxman, and Co., in the electric light department, were seen, and then the members proceeded to the New Technical Institute, where they had explained to them the experiments being carried out to study the propagation of various forms of bacteria. Then other exhibits were visited till seven o'clock, when dinner was served in the jury room. The wine at dinner was provided by the liberality of Mr. Prinie, the representative of Italy at the exhibition, and was accorded the highest praise. Vice-Admiral J. Selwyn presided. After the usual loyal toasts "The Services" was proposed, Colonel Hope, V.C., responding for the army, and Captain Fairholme, R.N., for the navy. Mr. Gooch proposed "The Inventors' Institute," briefly referring to the value conferred upon humanity by inventors, pointing out that the institute should take a very high position and be well supported in its endeavours to put inventors and inventions upon a proper footing with the world at large. Mr. Stanfield responded, and spoke with great enthusiasm of the labours of Trevethick, of Wedgewood, and other pioneers in the industrial inventions of England. He maintained that we were not only a nation of improvers, but a nation of inventors, pointing his moral from the works of the men he named. Other toasts were drunk, one of which was the health of Mr. Mackie, the guide of the day. A pleasant evening concluded with the health of the chairman.

Before concluding this cursory notice of the proceedings, we may be allowed to make known the work and objects of the institute, which are thus stated:—

The objects of this institution are to afford opportunities to inventors of reading papers or exhibiting their inventions at its evening meetings; to facilitate the diffusion of information with regard to inventions generally; and to furnish a rendezvous for the interchange of views with colonists, Americans, and foreigners, on the subject of international patent law and other subjects of interest to inventors.

The institute is also intended to constitute a channel for facilitating the combination of inventors, manufacturers, and those interested in trade, in order to organise united action with respect to the changes still desirable in the Patent Law. . . .

An international exhibition of inventions is to take place at South Kensington in 1885, and inventors who intend to take part in it will do well to avail themselves of the advantages of this institute.

THE EASTERN TELEGRAPH COMPANY, LIMITED.

NOTICE IS HEREBY GIVEN that the TWENTY-FOURTH HALF-YEARLY ORDINARY GENERAL MEETING of the EASTERN TELEGRAPH COMPANY (Limited) will be held on THURSDAY, the 10th JULY, 1884, at ONE o'clock in the afternoon, at the CITY TERMINUS HOTEL, Cannon Street, London, when the Directors' Report and Accounts, for the half-year ended 31st March, 1884, will be presented, a Dividend declared, and the ordinary business of the Company transacted.

NOTICE is also given that the Register of Transfers will be closed from the 8th to the 15th July, both days inclusive.

By order of the Board,
GEORGE DRAPER,
Secretary.

London, 1st July, 1884.

WANTED.—A STUDENT or ENGINEER to join Advertiser, once a week or oftener, in reading Dynamo Machine Literature.—J. W., 50, Spencer-street, Goswell-road, E.C.

A WELL-KNOWN ELECTRICIAN is open to ENGAGEMENT. Long experience in Electric Lighting, Accumulators, Plating, and Cable Work. Good engineer.—Address, L. T., at C. H. May and Co.'s General Advertising Offices, 78, Gracechurch-street.

EXPERIENCED MECHANICAL ENGINEER and ELECTRICIAN seeks EMPLOYMENT. Well educated. Has had charge of important installations of Electric Light.—Address, A. B., *The Electrician* Office.

FOR SALE.—A Post Office Pattern WHEATSTONE BRIDGE (Elliott); quite new. Cost £26. What cash offers?—Address, H. A., *The Electrician* Office, 1, Salisbury-court, Fleet-street.

FOR SALE.—50 Lane-Fox SECONDARY BATTERIES and about 200 De Kabath ACCUMULATORS.—Apply to THE ELECTRIC LIGHTING SUPPLY AND FITTING COMPANY (Limited), 28, York-street, Westminster, S.W.

Digitized by Google

NOTES.

Electric Lighting in Theatres.—The Wilhelm Theatre at Cologne is to be lighted by electric lamps.

Western and Brazilian Telegraph Company.—The traffic receipts of this company for the week ending 4th July were £2,524.

Earthquake in India.—Indian papers report that several smart earthquake shocks were felt at Delhi between eleven and three p.m. on June 6.

Electric Lighting at Brighton.—The Orleans Club, Brighton, has been re-opened, and the principal rooms are now lighted with electric lights.

Kelway's Electric Log Syndicate.—Mr. Justice Kay has made an order for the voluntary winding up of this syndicate to be continued under the supervision of the Court.

St. George Telephone Company.—Creditors of this company should send their names and claims before August 19 to Mr. George Boggis, 14, St. Swithin's-lane, E.C., the official liquidator.

Eastern Extension Telegraph Company.—The traffic receipts of this company for the month of June, 1884, amounted to £31,787, and to £34,307 for the corresponding period of 1883.

Weather Telegrams in Victoria.—The Melbourne Observatory is, says *The Colonies and India*, making arrangements for supplying complete weather information to the country townships.

New Knight.—Her Majesty has been pleased to confer the honour of knighthood upon Professor Roscoe, F.R.S., in consideration of the services rendered by him in connection with the Technical Commission.

Rysselberghe's System of Telephony.—M. Cochery, the French Minister of Posts and Telegraphs, has allowed experimental trials of this system to be made on the telegraph line between Rouen and Havre.

The "Illustrated Science Monthly."—This magazine for July contains an article by Mr. G. W. von Tunzelmann on "Matter and Motion," and an interesting biography of Professor John Tyndall, F.R.S., with a portrait.

"L'Electricite."—After a somewhat chequered career our contemporary *L'Electricité* appears in new shape, with a new editor and apparently new proprietors. The management and direction is now in the hands of Dr. C. C. Soulages.

Cable Extension.—It is notified that the Eastern Extension Company's system has been extended to Macao by the laying of a submarine cable between that place and Hong Kong. The tariff from all stations in Great Britain is 8s. 9d. per word.

West Coast of America Telegraph Company.—At a meeting of the directors of this Company on Wednesday a dividend was declared of 4s. per share on the £10 shares, or at the rate of 4 per cent. per annum for the half year ending June 30 last.

Royal Assent.—On the 3rd inst. Royal assent was given by commission to the following Acts:—Electric Lighting Order Confirmation (No. 3) Act, 1884; ditto, ditto (No. 4) Act, 1884; India Rubber, Gutta Percha, and Telegraph Works Company Act, 1884.

Globe Telegraph and Trust Company.—This company announces a dividend of 3s. per share on the Preference shares, making a total for the year of 6 per cent.; and 3s. 6d. per share on the Ordinary shares, making a total dividend for the year of 4¾ per cent.

New Cable.—The managing director of the Brazilian Submarine Telegraph Company announces the successful laying of the second cable between St. Vincent and Pernambuco, thus completing the duplication of this company's entire system between Europe and South America.

Great Northern Telegraph Company.—The traffic receipts of this company for June, 1884, were £22,960; for the period January 1st to June 30th, 1884, they were £129,520, against £123,488 for the corresponding months of 1883, and £116,527 for the same period of 1882.

Electric Light in Manchester.—The contract for the lighting of the Clarence Hotel has just been placed with Mr. F. D'A. Goold, electrical engineer and contractor, of Manchester. The plant will consist of the necessary machinery for running 200 incandescent lamps.

Hotel Lighting.—The Waterloo Hotel in Manchester is to be lighted with the electric light. The work, which will comprise 200 incandescent lamps, has been placed in the hands of Mr. F. D'A. Goold, electrical engineer and contractor, 29, Arcade-chambers, St. Mary's Gate, Manchester.

South Eastern Railway Company—The Anglo-American Brush Corporation are opposing this company's (various powers) Bill, as, amongst other things, it seeks power to acquire land on which the corporation's works are situate for the purpose of widening the line at Charing Cross.

The Telephone for Mines.—The telephone is extensively used in the mining regions of Silesia. Several mines and factories are connected up to a central office at Benthuen. There are 112 subscribers, and the length of lines is 1,180 kilometres. The number of calls per day is over 322.

Mediterranean Extension Telegraph Company.—The liquidators of this company have been notified that the Bill authorising the transfer of the undertaking to the Eastern Telegraph Company has received the assent of both Houses of Parliament, and merely awaits the sanction of the King.

Faure Electric Accumulator Company.—At a meeting of this company, held on Tuesday, the resolutions for winding up the company voluntarily were confirmed, and Mr. Francis Cooper (Cooper Brothers and Co.), Mr. Herbert Canning, and Mr. Richard Alexander Brown were appointed liquidators.

An American Exhibition.—The idea of holding an exhibition of American manufactures and arts in London has been started. It is proposed to open the exhibition on 1st May, 1886. Mr. J. R. Whitley is the general director in London, and Mr. C. B. Norton is the secretary. The offices are at 7, Poultry, E.C.

Telephone Company of Ireland.—This company is inviting subscriptions for 5 per Cent. Preference Shares, payable 5s. per share on application, 5s. on allotment, and the balance as may be required at intervals of not less than three months, with power to the company to redeem the same at a premium of 10 per cent.

Ship Lighting.—The "Banshee," the latest addition to the London and North Western Railway Company's fleet of

Digitized by Google

boats for the Irish Channel service between Dublin and Holyhead, is lighted by incandescent lamps. She is a paddle steamer of 1,780 tons, and 3,500 indicated horse-power, and has been built by Messrs. Laird, of Birkenhead.

STENO TELEGRAPHY.—We have received from M. Cassagnes, C.E., a little pamphlet bearing this title, in which is a description of his proposed method of telegraphing shorthand, his idea being that reporters' shorthand notes of speeches, &c., can be telegraphed straight to the papers and transcribed in their offices, thus saving them much time and money.

NEW SHIP.—The Italian Royal Mail steamer "Regina Margherita," 3,700 tons, was launched on Wednesday from the building yard of Messrs. M'Millan and Son, Dumbarton. Her extreme length is 415ft., breadth 42ft., and depth 29½ft., and she has a promenade deck her whole length, 8ft. 6in above the main deck. She is to be lighted with the electric light throughout.

THE NEW BENNETT-MACKAY CABLE. — The steamship "Faraday" has picked up the buoy of the south cable she recently laid on completing the shore end of the cable at Waterville, about 200 miles from the Irish coast, and had on Tuesday paid out a further portion of cable to the extent of 250 miles. This makes about 450 miles paid out from the Irish coast. The weather is splendid for cable operations, and the work is expected to be shortly completed.

ELECTRIC LIGHTING IN MELBOURNE.—The Anglo-American Brush Electric Light Corporation have received a large order from the Australian Electric Light, Power, and Storage Company, for electric lighting apparatus. The machines ordered are five Victoria machines of the size known as the F_2 250 lighter, and one 100-light D_2 machine, together with a large number of Victoria incandescent lamps. This plant or the greater part of it will be used for working the electric light to be installed in the Parliament Houses of Melbourne.

TELEGRAPH EXTENSION IN ORKNEY.—In the House of Commons on Thursday, the 3rd inst., Mr. Courtney, replying to Mr. Barclay, said that the main recommendations of the Crofters' Commission in favour of increased telegraphic facilities in Orkney and Shetland had already been anticipated under an arrangement with the Fishery Board. Looking to the unremunerative character of the telegraph service at home, it was scarcely possible to dispense with the guarantee now required before providing such telegraphic communication.

MANGANESE MINES IN NOVA SCOTIA.—Some interesting information has recently been given before the Royal Society of Canada regarding the manganese mines of Nova Scotia. It was stated, as a result of surveys and investigations, that the manganese ores of this province occur low down in the carboniferous limestone, below the gypsum deposits characterising that stratum, and that they are connected with limestones frequently manganiferous, and usually so magnesian as to approach dolomites in composition. The ores are, it is found, of unusual purity.

ELECTRIC LIGHTING IN FINLAND.—Messrs. Astrom Brothers, of Ulealong, Finland, are about to light their tanneries by incandescent lamps, and have placed the order for the necessary apparatus in the hands of the Anglo-American Brush Corporation. The plant will consist of one D^2L Victoria dynamo, compound wound, for eighty 20 candle-power and eighty 10 candle-power Victoria lamps, together with the necessary fittings and cable. The whole of the work will be superintended and carried out by the Corporation, who are about to send one of their assistant engineers to Ulealong for that purpose.

ELECTRIC LIGHTING IN BELFAST.—On the occasion of the ball given in honour of the recent visit of his Excellency Earl Spencer, K.C.B., to Belfast, the lighting of the Ulster Hall was effected by electric lamps. The main hall was illuminated by six arc lamps of the Newton type, while the vestibule and staircases were effectively lit by means of Swan incandescent lamps to the number of about 40, tastefully arranged on existing and special fittings, or in hanging baskets of flowers and ferns. The entire work was carried out by the Belfast Electric Appliances Company, under the supervision of their manager, Mr. Geo. Annesley Grindle.

TELEGRAMS AND THEIR USE.—"M." writes to *The Times* of July 9:—"Last evening (July 3) an important telegram was handed in at the House of Commons office at 8 o'clock. It reached me in Cornwall-gardens a few minutes after 9. To-day I myself put in one at the same office, which it was equally important should reach the City in a few minutes. The clerk retained it in his hand and went on receiving others. I begged him at least to hand mine to the operator, whereupon he calmly replied, 'Oh, that is no use; there are several before yours.' I took it and my money back, and sent a messenger. If this sort of thing can happen from important centres, is not telegram sending rather a farce?"

MAXIM-WESTON ELECTRIC COMPANY—A notice has appeared in the *Gazette* to the effect that the order of the High Court of Justice, dated 14th June, confirming the reduction of the capital of the above company from £500,000 to £250,000, and the minute showing the particulars required by law were registered on the 2nd July. The minute reads as follows:—"The capital of the Maxim-Weston Electric Company is £250,000 divided into 500,000 shares of 10s. each. At the time of the registration of this minute 200,000 of the shares have been issued, of which 190,000 are deemed to be fully paid up and 2,000 of such shares are deemed to have 19s. per share paid up thereon, and the remaining 300,000 have never been issued."

REMARKABLE FEAT IN TELEGRAPHY.—"J." writes to *The Times* of July 4 as follows:—"On Tuesday last I sent a telegram from East Croydon to Westminster at twenty minutes to 10 a.m., and it positively reached its destination at Bridge-street seven minutes under the hour—*i.e.*, at 10:33. I arrived there myself (by train) at ten minutes past 10, and thus I was enabled with a little patience to witness the arrival of my own telegram twenty-three minutes later. A few days ago I sent a telegram from East Croydon to Brighton, and that arrived almost in the same time. If things go on at this rate I would suggest the desirability of some one presenting a testimonial to the telegraphic authorities in order to stimulate them to still greater exploits."

SUBMARINE EXPLORATION.—M. Toselli has designed a kind of magnified diving bell, containing three different chambers, which can be let down into the sea from a vessel for submarine exploring purposes. It is formed of a steel cylinder some ten metres long and three metres diameter, fitted with a winding staircase leading down through the different compartments. It is of course air tight, and is supplied with two reservoirs of compressed air for the explorers. Telegraphic and telephonic communication is provided to facilitate communication with the ship, and the three compartments are all lighted by incandes-

Digitized by Google

cent lamps. The bottom compartment is fitted with a number of windows through which the observers can investigate their marine surroundings. An experimental trial at Nice has given good results, and we believe the designer intends building a still larger apparatus for exploring the sea at greater depths. Messrs. Imbert Bros., of Nice, are the constructors of his first apparatus, which he has named the "Neptune."

INDUCTION ON UNDERGROUND AND OVERHEAD WIRES.—This subject was dealt with by Mr. F. N. Gisborne, in a paper read at the annual meeting of the Royal Society of Canada, held at Ottawa at the end of May. The author proposed to get rid of induction effects in telephone circuits by connecting the sending and receiving telephones by means of pairs of twisted and insulated wires. He described experiments made with a section of cable about 3,000ft. in length and laid underground between two of the departmental buildings at Ottawa. The cable contained 20 indifferently insulated wires, which were divided into pairs, two wires being twisted together in each case, each pair constituting a metallic circuit, and one wire of each pair being used as a "return" instead of the earth plates usually employed. The experiments showed that if one of these pairs was used as a telephonic circuit, no induction effects could be observed in the others. The absence of induction he attributed to the equidistance of the two wires of a pair from any third wire and the equality and opposition of the currents flowing in them.

MILL LIGHTING.—Mr. J. F. Milner, proprietor of the Woodside Mill, Elland, Yorks, has introduced the incandescent system in his mill. The installation consists of one Crompton Burgin compound self-regulating dynamo machine and some 76 20 candle-power Swan incandescent lamps. It is intended to add to the number of incandescent lamps on the completion of Mr. Milner's new offices. It is also intended that there shall be an arc lamp on each side of the mill for loading purposes; these will be of the well-known Crompton-Crabbe double differential type. The dynamo is placed on the top floor, where it is driven by a small separate engine, which, although intended to drive the hoist, answers admirably for driving the lights, as it can always be kept running if desired. It is driven by a countershaft at a speed of 1,400 revolutions per minute. The E.M.F. at the terminals of machine and lamps is 110 volts. The work has been carried out under the superintendence of Mr. J. T. Baron, on behalf of Mr. Wilson Hartnell, electric light contractor, of Leeds. Mr. Hartnell's success in mill lighting is without doubt due to the care with which he carries out his installations. In his hands the electric light should gain the prestige which it has lost in some instances by reason of the carelessness and incompetency of the men who have had the working of it.

OVERHEAD WIRES.—In the *Pall Mall Gazette* for Tuesday last Professor Silvanus P. Thompson writes on this subject. Those best qualified to speak on the subject from long experience agree, he says, that the life of every wire is limited, and none can tell how or when a wire may snap. The internal flaws do not reveal themselves when the line is erected, nor can they be detected after the line has been put up except by the actual breaking of the line. Professor Hughes has established the fact that every vibration imparted to a wire brings it a stage nearer to a state of internal crystallisation, when it snaps short, its fibrous structure having completely degenerated. Most of the existing telephone wires are only five or six years old; another five years and there will be a fine crop of accidents to report. Common sense suggests as the obvious remedy that already adopted in other great cities, namely, the laying of the wires underground in proper channels under the road or kerbway. The somewhat greater prime cost of doing this would be met in a very short time by the counter gain in having practically no renewals or repairs, and no deterioration of any moment in the wires laid underground. It would take an earthquake to dislocate or break them. Professor Thompson thinks there can be no doubt which way public opinion is tending, and exclaims as he lays down his pen, "Let us be wise in time."

A NEW SYSTEM OF PAINTING IRON.—A process, on a new principle, for protecting iron and steel from corrosion (especially when submerged) has been patented by Mr. F. Maxwell-Lyte, F.C.S. The theory of the process, says a contemporary, is essentially electrical, and its utility is based upon the hypothesis that the oxidation of iron and steel is much accelerated by, if not wholly due to galvanic action. The metal to be protected is first coated with one or two primings of an oxide of a metal electro-positive to iron, upon which any of the ordinary anti-fouling or oxide paints may be applied. These latter always contain the oxide of a metal electro-negative to iron, and this oxide will consequently always be reduced, and the iron oxidised in time. The priming employed by Mr. Maxwell-Lyte is composed of oxide of zinc or magnesia, particularly the latter; and this not only protects the iron, but keeps it from contact with the outer coat. It is claimed that something of this kind has always been used whenever painting of iron has been even partially successful; but that the guiding principle—the use in the first place of a material electro-positive to iron—has been overlooked. Red lead as a priming does fairly well for a time, because though lead is electro-negative to iron it is only slightly so. Better protection is assured by the use of a distinctly basic material.

UNDERGROUND WIRES FOR NEW YORK.—The following is the text of the law requiring telegraph and electric light wires to be put underground in cities of more than 500,000 inhabitants in the State of New York:—Section 1. All telegraph, telephonic, and electric-light wires and cables used in any incorporated city of this State having a population of 500,000 or over, shall hereafter be placed under the surface of the streets, lanes, and avenues of said cities. Section 2. Every corporation, association, or person owning or controlling telegraph, telephonic, electric, or other wires and cables, including what is known as telegraph-poles, and other appurtenances thereto, shall, before the 1st day of November, 1885, have the same removed from the surface of all streets or avenues in every such city of this State. Section 3. In case the owners of the property above enumerated shall fail to comply with the provisions of this Act within the time herein specified and limited, the local governments of the said cities of this State shall then, and they are hereby directed to remove, without delay, all telegraph, electric-light, and such other wires, cables, and poles, wherever found above ground, within the corporate limits of their respective cities. Section 4. No city in this State shall grant any exclusive privilege or franchise under this Act to any corporation or individual by which a monopoly may be created or competition prevented on equal terms. Section 5. This Act shall take effect immediately.

SULPHATE OF COPPER SOLUTIONS.—Professor J. G. MacGregor has been making extended researches on the density and thermal expansion of aqueous solutions of copper sulphate, and communicated the results of his investigations

Digitized by Google

in a paper read at the annual meeting of the Royal Society of Canada, recently held at Ottawa. He finds that the rate of variation of density with temperature increases with the temperature and with the percentage of salt in solution; that the density of any solution at low temperatures (below 20° C.) diminishes, as the temperature increases at a greater rate than that of water; that the ratio of the density of a solution to the density of water at the same temperature diminishes as the temperature increases; and certainly for many solutions, probably for all, attains a constant value within the temperature limits of the experiments (below 35°-50°); that, therefore, at about 40° C. the thermal expansion of solutions is the same as that of water at the same temperature. The experiments also substantiated a result formerly reached by Professor Ewing and the author, that very weak solutions of this salt have a smaller volume than the water used in making them. If then these solutions are made by the addition of anhydrous salt to water, contraction must occur. The experiments show that the greatest contraction occurs in the case of a solution containing 1·34 per cent. of anhydrous salt, in which case the contraction is 0·0048. The solution containing 5·95 per cent. of anhydrous salt has the same volume as the water required to make it.

PYRO-ELECTRIC PROPERTIES OF BORACITE.—The optical, thermic, and pyro-electric properties of boracite have been the subjects of a series of investigations by Hauy, Hankel, Mallard, Baumhauer, and others. Herr Mack has recently made researches based upon an observation of Kundt that Lichtenberg's figures can be used for an examination of the pyro-electric properties of crystals. A description of his experiments appeared in *Wiedemann's Annalen*, Vol. XXI., pp. 410 to 421, and the following abstract is given in the Chemical Society's *Journal* for June :—"The method of observation consisted in heating the crystal to be examined in an air bath, removing it by a pair of pincers previously heated in the same bath. The crystal is then passed through an alcohol flame and placed on a slip of wood or paper, where it is dusted thoroughly with the ordinary mixture of sulphur and red lead. On cooling, the particles of these substances arrange themselves in definite lines, thus marking out the field of positive and negative electricity. The crystals examined were cubical, rhombic, dodecahedral, and tetrahedral, obtained from Stassfurt and Luneberg. The general results of the investigation may be summed up as follows: 1. The difference of potential, whether positive or negative, does not extend over the whole surface of a crystal, but follows certain definite lines. 2. If upon a crystal, in which either the rhombic or dodecahedral form is dominant, there be conceived to be marked out a smaller, perfect rhombic dodecahedron, so that its principal crystallographic axes coincide with those of one or other of the above crystals, and there be projected from the common middle point, the angle of the latter dodecahedron upon the surface of the crystal, then a system of lines is obtained, coinciding with the lines of the electro positive or negative potential differences. Those lines which connect the middle points of smooth and glistening tetrahedral surfaces are coloured yellow, but those which lie symmetrically to any principal symmetrical plans of the regular system are red. This system of lines coincides with the optical system of lines of double refraction which have been described by Klein and Baumhauer. It would appear, then, that there is an intimate connection between the optical and pyro-electric properties of boracite. The former are probably conditioned by a state of tension of crystal, and the experiments of T. and P. Currie would seem to point to the same conditioning of the pyro-electricities.

ELECTRIC LIGHTING AT THE HEALTH EXHIBITION.—A large part of the grounds and buildings of the Health Exhibition at Kensington are being illuminated by arc and incandescent electric light apparatus, supplied by the Anglo-American Brush Corporation. The number of arc lights used is 25, that is including the two lamps in parabolic reflectors used for throwing the rays of light on to the central fountain when working, which are fixed on the central gallery. These 25 lamps are of the well-known Brush arc type, 23 being the ordinary 2,000 candle-power type, and the two in the reflectors the automatic lamps used for head lights on ships. For indoor use the lamps are fitted with ornamental brass covers, and crowns are placed in hexagonal lanterns in the grounds. The machine driving these lamps is, however, the chief feature of this exhibit. It is a No. 7 Brush 16-light sized machine, but is fitted with Mr. Brush's new patented armature, which is the property of the corporation. This new improvement renders the machine capable of running half as many lights again as when fitted with the old form of armature. The machine at the Health Exhibition is never running less than 23, and often 24 lamps, with the same degree of brilliancy as it used to run the 16 with the old armature. A remarkable feature in this armature is that it keeps cool when the machine is working, and remains so even after a long run. Some of the portions of the Exhibition lit by the company's arc lamps are the East and West Annexes, the Central Annexe, Clements & Co.'s stand, &c. Their incandescent lamps will be found at the exhibit of the Dowson Economic Gas Company, a compound D_2 Victoria machine being used, with about 100 20 candle-power Victoria lamps for lighting the exhibit. The machine is driven by one of Messrs. Crossley's new double cylinder Otto engines, and the gas for driving it is made by the gas company's plant there. In the electric light machinery shed there is a D_2 Victoria machine, driven by means of a Parson's high speed direct acting engine, which is remarkable for silence and freedom from vibration in working. The Victoria machine operates some 100 lamps of 100 volts, placed in Lockhart's Cocoa Rooms, some being used in the refrigerating chambers in the Western Annexe. Another D^2 machine, similarly wound to that in the electric light shed, is about to be placed there for driving a number of incandescent lamps. This machine will be driven by a Tower spherical engine, made by Heenan and Froude, of Manchester.

ELECTRICITY APPLIED TO WEAVING.—The late Comte T. du Moncel contributed an interesting article on this subject to the paper with which he was connected, and an abstract has been published in the "Abstracts of Papers in Foreign Transactions, &c.," published by the Institution of Civil Engineers, as follows:—"Of the various applications of electricity, none have progressed more slowly than that which was made nearly thirty years ago in the weaving shed. The journals of 1855 and 1856 were full of the marvellous results furnished by this application, which was to supersede the Jacquard looms by substituting electric interruptors for the Jacquard cards. The author first deals with the Bonelli system, and to make his description clear he explains the principle of the Jacquard loom. In the Bonelli system, the lower part of the Jacquard loom is maintained, but the crotchets are terminated in an iron head resting on a tringle or bar of wood connected to the pedal. This tringle, or these tringles, for there are several, are, by the pedal, raised to the height of one or several series of straight electro-magnets in number equal to the crotchets. A metallic cylinder, or an endless metallic cloth working on two cylinders, together with a series of points communicating with the electro-magnets, constitute the means of making and

Digitized by Google

interrupting contact and controlling the displacement of the crotchets. The design is traced in insulating parts and in conducting parts on the cloth or cylinder, and such an arrangement for only two colours is extremely simple; but for more highly-charged designs, such as cashmeres, Bonelli constructed a special transmitting apparatus. This is composed of two parts, a grated composing frame and a comb with movable teeth. There is also a frame in which are ranged, according to the different shades of colours and the space these should occupy, small pieces of metal of different lengths (varying according to the order of the colours) and of different widths (varying as to the space these should occupy on the design). These pieces are of the same thickness. Over them, constituting an unequal face, are passed the movable teeth of the comb. As the teeth of the comb are each in connection with one of the electro-magnets of the loom, at each movement of the pedal the crotchets related to each colour are raised at the same time. In Maumene's system the electro-magnets are caused to act directly on the needles, which in the ordinary Jacquard loom uphold the crotchets. By this arrangement the ordinary machine is preserved nearly intact. A cylindric commutator is employed. In Pascal and Mathieu's system a plate of copper that has received the design is placed vertically and laterally with relation to the crotchets sustaining the threads. It turns on a cylinder without total displacement. In Gand's system the electro-magnets act directly on the crotchet bars, and fixed conducting wires are substituted for the movable needles of the Jacquard loom, which are subject to frequent disarrangement. And instead of the Jacquard cards paper bands are employed placed over a polygonal frame. Regis's system is a modification of that of Gand. A later system by Bonelli discards the commutator, or rather substitutes an inverse arrangement, and instead of making a conducting surface insulating, an insulating surface is metallised. In the former case the insulating material wore away and clogged the contact brush. The designer draws on paper with the aid of a sticky varnish the pattern to be produced in the tissue. The design is then covered with a sheet of tinfoil, which is allowed to remain in contact for about half an hour. The paper is then rubbed with a cotton pad, the tin remaining adherent where the varnish is, and elsewhere disappearing. The author appeared to be of opinion that further valuable improvements are to be anticipated.

THUNDERSTORMS.—The hot weather of the past few weeks has had its natural termination in a series of violent thunderstorms, which have caused considerable damage to property and resulted in the loss of several lives throughout the British Isles. On Friday, the 4th instant, a horse was killed by lightning while grazing in a field at Barrowford, near Burnley, Lancs., and two men who were sitting near were struck, but were not killed. At Northampton on the same day several houses and a factory were damaged by lightning. Two men at work in a field at Aston, near Wallingford, Berks, were killed, their clothes being burnt off their bodies; a horse was also struck and killed. Near Wymeswood, on the same day, viz., Friday, two brothers and their nephew at work in a hayfield took shelter under a hedge, and were all struck by lightning. According to a report of the occurrence in the daily papers the nephew felt a sharp pain on the thigh and became senseless. On recovering he found that one uncle had fallen and the other was sitting, looking placid and apparently undisturbed, but on examination he found both were quite dead. The storm was exceptionally violent in the Loughborough and Charnwood Forest district, and it is feared the damage is considerable. In Scotland also the storm was severe, houses being struck in Forfarshire, Perthshire and Fifeshire. On Saturday Holy Trinity Church, Everton, Liverpool, was struck by lightning, two boys within the building being seriously hurt, and the congregation thrown into panic. A stable on the farm of Sir B. Bridges, at Goodnestone, was set on fire by the lightning, and three valuable horses were burned to death. At Cambridge a woman was killed and two or three buildings set on fire by the flashes of lightning. A Wesleyan chapel at Lane Head, Weardale, Durham, was struck and two men were injured. In the island of Skye several houses were damaged, and at Fort William a young man was killed by lightning. At Edinburgh on Friday a remarkable phenomenon was observed. A thunderstorm came on at the time of a rather dense fog, which had for some days been hanging over the east coast of Scotland. The lightning flashes, which were extremely vivid, produced, it is said, a weird effect in illuminating the foggy atmosphere. The Coroner for North Oxon held an inquest on the body of William H. Smith, a painter and landowner, who was killed during a thunderstorm at Deddington on Friday. The deceased was taking shelter under a tree, and was about to partake of dinner, which his wife had just brought him, when the lightning struck him and killed him instantaneously. The wife felt the shock, but was not seriously injured. A verdict of killed by lightning was returned. During the thunderstorm which swept over the district of Consett on Sunday afternoon, Thomas Gill, a miner, who was nursing an infant on his knee, was struck by lightning and killed. The child escaped. The house and furniture were much damaged. The storms continued through Monday, Tuesday, and Wednesday. On Tuesday a cottage was fired at Preston, Lancashire, and it was reported that several persons had been struck by the lightning. At Crewe a boy named William Edward Morris was killed whilst returning from cricket; his face, shoulder, and right side were much burned, his clothes torn, and both his boots were ripped from his feet. Houses were damaged, and several persons had narrow escapes. At Coventry the lightning struck a man insensible, but he is expected to recover. On Wednesday a storm, accompanied by heavy rain, and some snow and hail, passed over Oldham, and two gangers who entered a hut for shelter, near to the Royton Spinning Company's new lodge, were killed, and three or four others more or less injured. At Preston buildings were struck and cattle killed. A severe storm broke over Leeds about six o'clock. Hailstones of an extraordinary size fell, and much damage was caused by the heavy downpour of rain. In the district of Retford 30 sheep, the property of a farmer named Twidale, of Upton, were killed whilst sheltering beneath a tree, and two cows—one at West Drayton and the other at East Markham—were struck whilst grazing in the fields. A storm also broke over Warwickshire, Leicestershire, and the central Midland districts. Two beasts were killed in a field near Heather, and at the village of Kersley twelve sheep were destroyed. Trees were split, chimney pots were shattered in all directions. At Rothwell a man named James Hainsworth, an engine-driver at the collieries, was struck dead by lightning whilst on his way home from work, and two of his companions were rendered insensible. In Hertfordshire the storm was very severe. As Mr. Judson, a farmer of Kilton-in-Cleveland, was carting hay on the same day (Wednesday), assisted by three of his men, all four were struck by lightning, and rendered temporarily blind. At Bramley Station (Yorkshire) the lightning set fire to the roof. It may be remarked that the barometer appears to have remained remarkably steady during these storms.

ELECTRO-CHEMISTRY.—Inorganic.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 174.)

Electrolysis of Sodium Carbonates.—Na_2CO_3 and $NaHCO_3$. According to Favre and Roche, by electrolysis, neutral sodium carbonate splits up into $CNa.O_3$ and Na., the sodium being oxidized by the water with separation of hydrogen. The acid carbonate is resolved into Na and CHO_3, the sodium being then oxidized and hydrogen evolved; the $2CHO_3$ is then resolved into $2\ CO_2 + H_2O + O$. According to Burckhard, sodic carbonate in a state of fusion is a good conductor, and is decomposed by electrolysis into carbonic acid at the anode, and soda together with a little carbon, at the cathode (*Chem. News*, Vol. XXI., p. 238).

Electrolysis of Biborate of Sodium.—Fused borax yields oxygen gas at the anode and boron at the cathode. The boron is separated by indirect action; the current resolves the soda into oxygen and sodium, and the latter separates boron from the boracic acid (Faraday, Gmelin's "Handbook of Chemistry," Vol. I., p. 460). Burckhard states that fused borax conducts, suffers electrolysis, and a series of compounds are formed or volatilised; but the chief result is that the salt is decomposed into soda and boron at the cathode and oxygen at the anode (*Chem. News*, Vol. XXI., p. 238).

Electrolysis of Sodic Sulphate. — Na_2SO_4. Molecular weight = 140. By the electrolysis of this salt in a fused state with platinum electrodes, sodium is deposited and combines with the cathode (Brester, *Chem. News*, Vol. XVIII., p. 154).

From the results obtained by electrolysing sulphide of sodium, Buff concluded that all the sulphur travelled to the anode and the sodium towards the cathode (*Chem. News*, Vol. XV., p. 279).

Electrolysis of Diphosphate of Sodium.—Na_2HPO_4. A solution of this substance is decomposed by a separate current into phosphoric acid at the anode and soda at the cathode. According to Faraday, acid phosphate of sodium in a state of fusion yields hydrogen at the cathode (Gmelin, "Handbook of Chemistry," Vol. I., p. 460). According to Burckhard, fused pyrophosphate of sodium, electrolysed with platinum electrodes, yields phosphide of platinum; but the chief result is that the salt splits up into oxygen, phosphorus, and soda (*Chem. News*, Vol. XXI., p. 238).

For the reducing action of sodium amalgam on solutions of silver, mercury, iron, and chromium, see the sections relating to those metals; also Watts's "Dictionary of Chemistry," Vol. VI., p. 816. For Jablockhoff's process of making sodium by electrolysis, see *Scientific American*, Sept. 22, 1883, p. 643.

Separation of Potassium.—K. Electro-chemical equivalent = 39·1. A monad cation. Magnesium, by simple immersion in a solution of potassic dichromate, forms potassic hydroxide (S. Kern, *Jour. Chem. Soc.*, 1876, Part II., p. 479). Zinc amalgam immersed in a solution of caustic potash liberates pure hydrogen (Watts's "Dictionary of Chemistry," Vol. III., p. 891). According to W. Skey, an aqueous solution of potassic chloride becomes alkaline by contact either with zinc or with silver, in the first case, probably by decomposition of water and formation of ammonia, aided by formation of zinc oxide, and in the second by oxidation of the silver by free oxygen, and the subsequent decomposition of that oxide with formation of silver chloride and caustic potash (*Jour. Chem. Soc.*, 1876, Part II., p. 266). Both carbon and iron separate potassium from melted potash at a white heat, and the process for obtaining potassium is based upon this fact. Brester states that even silver will dissolve in large quantities in melted potassic hydrate (*Chem. News*, Vol. XVIII., p. 145), and I have observed that when this hydrate is melted in a pure silver crucible the vessel loses in weight.

Electrolysis of Potassic Hydrate.—KHO. Molecular weight = 56·1. Potassium was first separated by electrolysis in the year 1807 by Sir H. Davy. He moistened a piece of potassic hydrate with water, placed it in a platinum capsule, which acted as a cathode, and touched the hydrate with the platinum wire anode of a battery of from 100 to 200 of Wollaston's cells. The potash liquefied, and globules of the metal separated at the cathode. Since that time it has been found that even a feeble voltaic current will liberate potassium from aqueous solutions of some of its salts, and if the deposited metal is protected from oxidation by being deposited into a cathode consisting of a large bulk of mercury with but a small portion of its surface exposed to the liquid, the potassium can be obtained in the form of its amalgam.

When mercury is placed in a cup connected with the cathode of a voltaic battery of at least 20 pairs, and covered with a strong solution of caustic potash, in which a piece of that substance is immersed, and into which the anode dips, the mercury takes up potassium (Berzelius, Watts's "Dictionary of Chemistry," Vol. III., p. 889).

According to Janeczek, when melted potash is electrolysed oxygen is evolved at the anode and potassium at the cathode, but no hydrogen; but if the experiment is made in a closed apparatus, after some time it is found that water is evolved with the oxygen, and some hydrogen is also set free; the latter probably results from the action of the potassium upon the melted alkali (*Jour. Chem. Soc.*, 1876, Part I., p. 182; also Watts's "Dictionary of Chemistry," Vol. VIII., Part I., p. 709).

Brester states that in the electrolysis of melted caustic potash an anode of either platinum, silver, or copper dissolves in the liquid, and the respective metals are deposited upon the cathode (*Chem. News*, Vol. XVIII., p. 145).

Electrolysis of Potassic Nitrate.—KNO_3. Molecular weight = 101·1. Some information has already been given of the effects of an electric current upon this compound (*see* "Electrolysis of Oxides of Nitrogen"). According to Faraday, an aqueous solution of it conducts electricity very easily, and yields hydrogen at the cathode.

Electrolysis of Potassic Fluoride. — KF. Molecular weight = 58·1. Fremy electrolysed fused potassic fluoride, and obtained a gas which rapidly attacked platinum, decomposed water, with formation of hydrofluoric acid, and displaced iodine from metallic iodides (Watts's "Dictionary of Chemistry," Vol. II., p. 673). The following are experiments of mine made with this substance:—I fused 130 grains of the pure salt in a platinum crucible within a partially covered clay muffle inserted in the hole in the top of a small gas furnace, and electrolysed it during two and a half hours, by means of a current from six Smee's cells, and two flat helices of platinum wire as electrodes. There was free conduction and much gas (of an odour like that of hydrofluoric acid) evolved from the anode, but none from the cathode, and no signs of any deposit. The anode was not corroded, nor altered in weight. I also electrolysed some of the same salt in a state of fusion by means of a current from six Grove's cells, with a thick platinum wire as the anode and the platinum vessel as the cathode. Great heat was evolved, and violent electrolytic action occurred; nearly white hot metallic globules also accumulated and exploded repeatedly. The end of the anode fused, and particles of platinum ramified from it in white hot threads, and a short electric arc (about 1-10th of an inch in length) was produced.

I also perfected and used a somewhat elaborate platinum apparatus, by means of which the gas from the anode was prevented from coming in contact with the cathode, and might be collected, the electrodes being enclosed within (but isolated from) two wide platinum tubes. One thousand grains of the perfectly pure salt were electrolysed in this apparatus by means of a current from six Grove cells. The anode, which was a solid rod of platinum, was rapidly corroded, and was thus cut off at the level of the liquid and stopped the current; the corroded surface was very bright, as if fused. Potassium was deposited upon the cathode. Much spongy platinum was diffused in the melted salt, and the apparatus was a little corroded at the surface of the liquid. No gas was evolved at the anode. The deposited potassium did not alloy with the stout rod of platinum used as the cathode. ·55·35 grains of grey metallic platinum were found in the saline mass; a salt of platinum appeared to have been

Digitized by Google

formed at the anode, then dissolved or diffused throughout the liquid and decomposed by the heat, and thus the liberated fluorine did not escape at the anode, but was evolved in the mass of the liquid generally, and came into contact with the liberated potassium.

Having ascertained the electrical relations of palladium, gold, platinum, and iridium in the fluoride, palladium being the most positive and iridium the most negative, I repeated the experiments with an anode of iridium and a current from three Grove cells. Copious clouds descended at once from the anode, and made the liquid opaque; there was also a violent action at the anode. The anode became black, and a little gas was evolved from it, accompanied by an acid odour like that of a mixture of sulphurous anhydride and hydrofluoric acid. Potassium was freely liberated at the cathode, and produced occasional explosions. With a current from six cells the anode dissolved rapidly, and soon lost thirty-eight grains. I then put a pure gold anode, and employed two cells. Gas, of a feebly acid odour, was freely evolved at the anode; and with a current from six cells was very copious, and smelt much like sulphurous anhydride. The gold dissolved much less rapidly than the iridium. With a palladium anode and a current from six cells the anode rapidly dissolved, potassium was deposited, and exploded frequently, and an odour like that of hydrofluoric acid was strong, much gas being liberated; 33·3 grains of free metal were found in the saline mass. The platinum cathode was not corroded.

In the experiments the platinum anode dissolved, as if melted; the iridium one was black, the palladium one was oxidised of various colours. The platinum vessel was cut into at the level of the surface of the liquid, evidently not by the fused fluoride of potassium, but by some substance set free at the anode by electrolysis. In another instance I electrolysed the pure fused fluoride with a large platinum anode, small platinum cathode, and a current from three Grove cells during half an hour. Much gas, having an odour of ozone and hydrofluoric acid, was evolved from the anode, and the latter dissolved rapidly and lost 37·5 grains in weight. The gas reddened test paper. The platinum containing vessel was corroded at the line of surface of the liquid, and lost about eleven grains. About fifty-one grains of free metallic platinum in loose powder was found in the saline residue. Each of these experiments shows that a very corrosive substance was liberated at the anode.

I electrolysed the fused salt with a gas carbon anode and a platinum wire flat helix as a cathode with a current from six Smee's cells. Free conduction occurred, and much gas was set free from the anode only. The part of the anode in the liquid was not visibly corroded.

I also electrolysed about 8oz. of pure double fluoride of hydrogen and potassium (KF HF) in a fused state during half an hour, at about 300° F., with a current from 10 Smee's cells, and electrodes of stout sheet platinum. There was copious conduction, and abundance of hydrogen evolved at the cathode, but no gas from the anode, which was rapidly corroded away, with a rough surface, and lost 9·37 grains. The salt became less fusible by loss of hydrofluoric acid, which escaped freely all the time. The saline residue contained a small amount of dissolved platinum salt, and nearly 9 grains of free metallic platinum. In a second experiment, lasting half an hour, the salt was kept only just fused, and a small gold anode was employed. The conduction was free, and much gas was evolved from the cathode, and a film of bright yellow gold spread over the surface of the salt, and connected the electrodes, unless the liquid was continually stirred. The anode rapidly dissolved (more quickly than that of platinum), and the salt of gold at once decomposed, and set free finely-divided gold as a dull, red-brown powder at the anode. No gas appeared at the anode at any time; that from the cathode detonated on applying a light. There was loose red-brown powder of gold, weighing 1·4 grain, upon the cathode, but of adherent gold only ·05 grain. The anode was corroded, and lost 6·80 grains. The saline residue contained no dissolved gold, but 5·85 grains of red-brown powder, containing 5·30 grains of gold.

THE INDUCTION OF CURRENTS IN CORES.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 134.)

Comparison of Current Induction in a Core with a Case of Fluid Motion.

In order to obtain a full mental representation of the state of things in a physical problem of one kind, it may often be of some assistance if we can find one of another kind in which the quantities concerned are similarly connected. Thus, in the theory of the torsion of a solid elastic prism, to get a general idea of the warping that takes place when the section of the prism is not circular, and of the amount of its effect on the torsional rigidity, we may be assisted by the comparison with a hydro-kinetic problem, in which the rotation about its axis of a box of the same shape as the prism, filled with incompressible perfect liquid, sets the liquid itself in motion when the section is not circular (Thomson and Tait, II., Art. 706). Suppose now the problem is one in which certain quantities subjected to given laws go through a series of complex changes in passing from one state to another. If we find another physical problem in which other quantities go through the same changes we have an interesting analogy, to say the least, even if the substituted problem be not more easily conceivable than the original. But further, if in the substituted question the quantities concerned are everyday realities, so that their connections are readily grasped, we have not merely an interesting but a useful and valuable comparison. Again, though this is quite a separate matter and may or may not apply, we may possibly get some assistance in forming a physical theory of the unknown phenomena for which has been found a dynamical analogue.

Start the current in a circuit containing a coil with a conducting core by closing connection with a battery. In the transition from the initial state of no current or magnetic force to the final state of steady current in the coil circuit alone and uniform magnetic force in the core, a series of complex changes, generally referred to as current induction, is gone through by the magnetic force and the current, and something more than a superficial examination is needed to obtain a good grasp of the phenomena as a whole. We require, then, an analogous case in which we can readily see the course of events. There are various comparisons which may be made, but the substitutions are not usually sufficiently simple for the purpose. The only one I can find that is so, is the comparison of the magnetic force in the core with the motion of water in a pipe of the same shape. This requires some explanation before the correctness of the comparison can be appreciated.

Magnetic induction is mathematically subject to the law of continuity of an incompressible perfect liquid. This alone is of valuable assistance when we are regarding the nature of distribution of lines of force in a magnetic field. Further, if we ask what it is in the liquid motion that corresponds to the electric currents that accompany the magnetic force, the answer is that a current line is represented by a vortex line, a current tube of infinitesimal section by a vortex tube of infinitesimal section, the fluid within which is, at the moment, rotating with an angular velocity proportional to the strength of current in the current tube, the axis of rotation being that of the tube. As current tubes are closed upon themselves, so are vortex tubes in a moving liquid. Any possible state of magnetic force with its corresponding electric current has its analogue in a similar state of liquid motion, lines of magnetic force being translated into lines of liquid velocity, and lines of electric current to vortex lines.

The Newtonian equation of motion of a fluid particle, meaning thereby an extremely small portion of the fluid, expressing symbolically the definition of a force as the acceleration of momentum it would produce if it lasted for the unit of time, is

$$F=\sigma\frac{Dv}{dt},$$

where σ is the density, F the force acting upon σ, or the force per unit volume, since σ is the mass per unit volume; σv the momentum, and Dv/dt the acceleration of σ's velocity. It is to be remembered that the force produces its full effect in the direc-

Digitized by Google

tion of its action, irrespective of what the actual velocity of the mass acted upon may be. F and v are vectors, and so is Dv/dt, which is a vector parallel to F.

The force F is partly due to the stress on the particle arising from the matter around it, and partly to other causes, which we sum up under the name of external force, acting bodily on the fluid, by unknown agency. The force of gravity, for instance, which appears to act upon matter independently of the matter around it, is treated as an external force.

In any fluid at rest, the internal stress is a simple pressure, equal in amount in all directions about a point, but in general varying in amount from one point to another. In the ideal perfect fluid this is also the state of stress when the fluid is changing its shape. The variation of pressure constitutes a force tending to alter the motion of a particle. Calling the pressure p, and disregarding external force, we have $F = -\nabla p$, the vector decrease of pressure, and

$$-\nabla p = \sigma \frac{Dv}{dt}$$

is the equation of motion of a fluid particle.

This insignificant-looking equation contains volumes of meaning, even without abstruse mathematical investigations to open them out. In fact, there is involved by it, and immediately visible when one looks at it through the proper glasses, a most remarkable property, that of the constancy of the circulation, with astonishing consequences.

The pressure p is a scalar—that is, it has a definite value at every point of the fluid, and requires no directional specification. Its variation $-\nabla p$ is, of course, a vector, has a direction as well as a magnitude, being in fact the force acting upon σ. Bearing this in mind, consider the state of the fluid at a fixed moment, and the alteration of velocity made by the force just after. Select a closed chain of particles, and travel once round it. However the pressure may vary along the circuit, it comes back to its original value at the end. In mathematical language the line integral of the force $-\nabla p$ round the closed chain is zero. By the above equation the same property must be true of the quantity on the right side of the equation, that is of the acceleration of momentum. Let σ be constant. Then the line integral of Dv/dt is zero. Now, defining the "circulation" in a closed circuit to be the line integral of the velocity, *i.e.*, $\int \overline{vds}$, where ds is a vector element of the circuit, its variation with the time is due, first, to the variation in the velocity, and, next, to the variation of form of the moving circuit; that is

$$\frac{D}{dt}\int \overline{vds} = \int \overline{\frac{Dv}{dt}ds} + \int \overline{v\frac{Dds}{dt}}.$$

We have already seen that the first integral on the right side vanishes. In the second, $\frac{Dds}{dt}$ is the rate at which the vector ds is changing, or the difference in the velocity at its ends, or $\frac{dv}{ds}(ds)$, making the quantity to be integrated $\overline{v\frac{dv}{ds}}(ds)$, or $\frac{d}{ds}(\frac{1}{2}v^2)(ds)$; which, being the variation along the circuit of a scalar, necessarily vanishes when summed up. Thus the circulation in the circuit does not change at all. The circulation along that circuit of particles, which may be any circuit in the fluid, whatever value it may have at one moment, will always have that value, and what is more always had it. Thus vortex lines move with the fluid, and vortex tubes keep their strengths unaltered, however they may change their shapes. This results from the constancy of the circulation along a closed line of particles embracing a vortex tube. The same reasoning applies when the density is not constant, but is a function of the pressure. Then $\nabla p/\sigma$ has the same property as that above mentioned for ∇p. Also, if the external force per unit mass be, like gravity, reducible to central forces, the same applies to it. From the constancy of the circulation in a perfect fluid we have the indestructibility and uncreatability of vortex motion, possible permanent differentiation of portions of the fluid from the rest, and Sir Wm. Thomson's vortex atoms. Truly there is poetry in science that infinitely transcends the schoolgirl poetry of belauded and belorded poets, which is, however, no doubt quite suitable for such matters as catching blue flies on the window pane, or calling me early, mother, dear.

Although the equations of motion of a perfect fluid were formulated by Euler in 1755-9, and dozens of eminent men had been working at hydro-kinetics later, a whole century elapsed before the property of the constancy of the circulation was discovered. No one had put on the right glasses, or had managed to focus them correctly, until Helmholtz in 1858 discovered the properties of vortex motion in a perfect liquid, followed a few years later by Sir W. Thomson's extension of the same to compressible perfect fluids, by his theorem of constant circulation, from which, in fact, they follow by elementary reasoning. We are here reminded of another doctor, who discovered another kind of circulation; we refer to Dr. Harvey, and the circulation of the blood. But the circulation of the blood is not constant. For the blood is a viscous fluid, requiring the continual application of force to keep up its circulation. That this is so is much to be rejoiced at by all good men; for, were it otherwise, we should live for ever, and no longer have, as at present, the inexpressible satisfaction of looking forward to a time when we shall console ourselves for the troubles of this life by playing on the harp in the next. Everything is for the best.

Now, since every state of incompressible perfect liquid motion represents a system of magnetic force, as the liquid moves and carries its vortices along with it, its motion remains the representative of the magnetic field of a definite system of closed electric currents similarly moved. But obviously this system of currents does *not* correspond to what would happen in a conducting mass if we started with a given arrangement of magnetic force and then left it to itself. For the magnetic system subsides through the frictional generation of heat by the electric currents which accompany it, whilst the constancy of the circulation precludes the motion of the perfect liquid ceasing. We must introduce viscosity, or internal friction; in other words, give the liquid that property which all known fluids possess. That real fluids are viscous is known to the commonest observation. When at rest, equilibrium requires that there should be no tangential stresses; when the parts of a fluid are changing shape there must be, because we can set fluids in motion by purely tangential stress. The typical illustration is that of the circular bowl containing water set rotating about its vertical axis. If there were no tangential stresses the water would remain at rest. In reality the tangential stress at its moving solid boundary pulls the outside layer of water round after the bowl, the outside layer pulls the next inner one, and so on up to the axis, where the water is the longest in getting up its motion. The final state is that the vessel and water rotate as one solid body. On stopping the bowl it drags back or retards the outer layer, then the next inside, and so on to the centre, where the liquid keeps up its motion the longest.

These tangential stresses are defined in amount by the coefficient of viscosity or of sliding friction. Let liquid be moving in horizontal layers in a definite direction, and let the velocity in any layer be proportional to its distance from the lowest layer, so that if x is the height of a layer, $v = ax$ is its velocity, a being constant. Let the motion be from left to right. Any layer is moving faster than the one below it, and slower than the one above it, and there is mutual stress of the frictional character between contiguous layers thus sliding, of amount ma per unit of area in contact, where a is the constant just mentioned—viz., the upward rate of increase of velocity, and m is the coefficient of viscosity.

Now in the equation of motion of a particle we have to take into account, in the expression for F, of any force on σ arising from the sliding friction set up by the distortion it experiences in general as it moves. The result, by the analysis of stresses and strains, is, in the case of an incompressible liquid, to introduce a new force acting on the particle besides that arising from variation of pressure. Not to go into details which are not wanted here, this force is represented by $-m\nabla^2 v$, which makes the equation of motion

$$F - \nabla p - m\nabla^2 v = \sigma \frac{Dv}{dt},$$

Digitized by Google

where F is restricted to be the external force only. The constancy of the circulation is gone, fluid motion may be started by tangential stress alone, and, should there be no forces to keep it up, will cease by surface and internal friction, the energy of the motion producing heat. The rate of dissipation for the whole liquid by internal friction is $4m\Sigma$ (ang. vel.)^2 per second.

But the special case to which our electrical problem corresponds is easily worked out. Let there be a long straight pipe of circular section, containing water or other practically incompressible viscous liquid, and let the motion be parallel to the length of the pipe, say from left to right, and be in cylindrical layers, *i.e.*, only varying in velocity from one layer to another. The cylindrical layers may slide over one another, but liquid must not move nearer to or further away from the axis of the pipe. Consider a layer of radius r and thickness dr moving with velocity v at r. The outward rate of increase of velocity being dv/dr (the a above), the whole tangential force on the inner boundary of the layer per unit of length of pipe is

$$2\pi rm\frac{dv}{dr} \text{ from right to left,}$$

and on the outer boundary,

$$\text{the same, } +\frac{d}{dr}\left(2\pi rm\frac{dv}{dr}\right)dr, \text{ from left to right.}$$

The resultant moving force is therefore

$$2\pi m\frac{d}{dr}r\frac{dv}{dr}dr, \text{ from left to right,}$$

which must equal the acceleration of momentum

$$2\pi r dr\sigma\frac{dv}{dt},$$

if there be no other forces. Equating the last two expressions we find

$$\frac{1}{r}\frac{d}{dr}r\frac{dv}{dr}=\frac{\sigma}{m}\frac{dv}{dt} \quad . \quad . \quad . \quad . \quad . \quad . \quad (62)$$

for the equation of motion of the layer of radius r. Comparing this with equation (14), for the magnetic force in the circular core inside a solenoidal coil, we see that they are of the same form. Magnetic force parallel to the axis is replaced by liquid velocity parallel to the axis, specific resistance by coefficient of viscosity, and magnetic permeability by liquid density. (Of course there is also the silly 4π in the electrical case, arising from the faulty definition of the strength of a pole.)

There may besides be, in the liquid, force arising from variation of pressure; but we do not require it. Let the ends of the long pipe be joined together, or immersed in the ocean, and let the liquid be set in motion by uniform tangential force applied to its boundary, acting parallel to the length of the pipe, of strength X per unit of surface. The surface equation of the liquid is of the same form as the boundary equation of magnetic force in the core, *i.e.* the equation of E.M.F. in the coil surrounding it. For, if m_1 be the coefficient of sliding friction between the liquid and the solid pipe, the frictional retarding force on the outer layer of liquid is m_1v per unit area, making $X - m_1v$ the actual force from left to right on the outer side of the boundary layer per unit area. On the other side of the layer, of infinitesimal thickness dr, there is the frictional stress acting in the opposite direction, of amount mdv/dr per unit area, so the equation of motion of the layer is

$$(X - m_1v) - m\frac{dv}{dr} = \sigma dr\frac{dv}{dt},$$

the right hand member of which vanishes with dr, thus giving

$$X = m_1v + m\frac{dv}{dr} \quad . \quad . \quad . \quad . \quad . \quad (63)$$

for the boundary equation. Comparing this with equation (20), which we may write (using (6) and (15),

$$\frac{E}{l_1} = \frac{R}{4\pi Nl_1}H + \frac{\rho}{4\pi}\frac{dH}{dr} \quad . \quad . \quad . \quad (20\text{A})$$

where l_1 is the whole length of wire in the coil, we see that the boundary equations are of the same form when the depth of the coil is small compared with its radius, and the core fills the interior space. (A modification can be made in the liquid problem to make the boundary equations agree when the coil is not of small depth.)

Having thus a perfect correspondence of mathematical conditions, we may, in considering the nature of induction in the core, dismiss altogether the complicated and cumbrous imagery of a set of currents acting and reacting upon one another at a distance, which it is only possible to manage in simple cases, and substitute the following method:—Let an E.M.F. act in the coil circuit, variable in any arbitrary manner. The magnetic force set up in the core will, at any moment and at every place, correspond in direction and intensity with the fluid velocity set up in a pipe similar to the core, filled with incompressible viscous liquid, if it be acted upon by superficially applied tangential force, uniform in amount per unit area, acting parallel to the axis, such force to vary in intensity in the same manner as the applied E.M.F. in the former case. Of course the viscosity, surface friction and density of the liquid must be properly chosen to suit the electrical data, as we may see on comparing (62) with (14), and (63) with (20a).

The wave-like propagation of magnetic force into the core from its boundary when an oscillatory E.M.F. acts in the coil circuit, and the rapid decrease of amplitude in going inward, and the insignificance of the magnetic force except near the boundary when the oscillations are rapid, are made perfectly easy to follow by the fluid analogue, wherein, with a similar to and fro tangential force on the liquid boundary, the motion is propagated inward by means of sliding friction.

In the core the current density is $-\frac{1}{4\pi}\frac{dH}{dr}$, and the current lines are circles in planes perpendicular to the axis. In the pipe the angular velocity of instantaneous rotation is $-\frac{1}{2}\frac{dv}{dr}$, and the vortex lines are similar circles. That the fluid moving in straight lines can be rotating will be seen by considering that if we impress upon every part of a small mass of the fluid in which the velocity varies a velocity equal to that of its central portion, but in the reverse direction—that is, do away with its bodily translational velocity—there is left only the relative motion of its parts, and that consists of a shear combined with an equal similar rotation. There is current in the core at any point only when the magnetic force varies in the neighbourhood, and in the liquid there is differential rotation only when there is sliding of layers. The heat of the induced currents corresponds to the frictional heat developed by the sliding, and the coil heat to the heat of friction against the pipe. The case of steady E.M.F. in the coil will be next considered, and graphically illustrated.

(TO BE CONTINUED)

ON MECHANICAL DYNAMOMETERS.

BY GISBERT KAPP.

(CONCLUDED FROM PAGE 81).

A handy form of belt-tension dynamometer for laboratory purposes is that devised and used by Mr. Alexander Trotter, to whom the author is indebted for the following particulars:—A loose-grooved wheel A (Fig. 35) is mounted in fixed bearings, and can be rotated either by a handle or by a belt from a prime mover. The wheel B, which is also grooved, is placed on the axle of the machine to be tested (which in Mr. Trotter's case was a model of a centrifugal pump, but might be a small dynamo or any other machine), and an endless cord is led round these two wheels, and also round two other wheels, D and C, weighted as shown. If A be turned in the sense of the arrow, that is, looking at the front elevation, against the hands of a watch, and the wheel B were not allowed to revolve, the result would be that the weight hanging on wheel C would be drawn up and the weight hanging on D would be lowered. The latter is lighter than the former, and if now A were held and B allowed to revolve, the heavier weight C would descend, drawing the lighter weight D up, and at the same time impart to the wheel B an amount of mechanical work exactly equal to that which previously had to be expended in lowering the light

Digitized by Google

and raising the heavy weight. In this way we could alternately expend mechanical energy on A and recover it from B. But this process can also be carried on continuously by allowing B to turn and put work into the machine under test, whilst turning the handle on it with such a speed as will just keep the two weights balancing each other. The mechanical energy which is thus put into wheel B is found by multiplying the difference of tension in the cord on either side with the speed of the cord. The speed is found by counting the number of revolutions of either B or A, and the difference in tension is of course half the difference between the weights on C and D. There is a slight correction to be made for the stiffness of the cord and the friction in the bearings of C and D. This can be found by running the apparatus idle.

One great advantage of this dynamometer is that irregularities of speed, which are almost unavoidable with a hand-driven apparatus, are not transmitted to the machine under test. The two weights which, so to speak, are kept floating, whilst balancing force and resistance, form a kind of reservoir of energy; and by slightly rising and falling in obedience to variations in the speed of the handle prevent these variations from reaching the wheel B. On this point Mr. Trotter says:—"In the experiments I had in hand the pump had to be driven with a uniform known velocity, and with a known expenditure

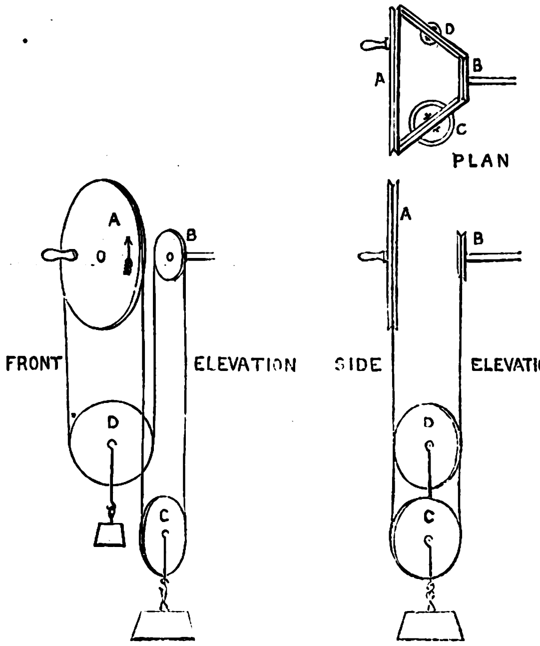

Fig. 35.—Trotter's Belt Tension Dynamometer.

of work. The power was supplied by turning the driving wheel by hand, and was about as much as a man could do. He could watch the movement of the weights, and when the heavier weight rose he slackened, and when it sank he quickened speed, the pump maintaining all the time exactly the same speed."

Hefner-Alteneck's Dynamometer.—This instrument, like that just described, depends on the principle of measuring the difference of tension in the tight and slack portion of the driving belt, but in the manner of taking this measurement there is an important difference. Whilst in Froude's, and also in Trotter's dynamometer, the measurement takes place in a direction parallel to a line joining the centres of the two pulleys, in Alteneck's instrument it takes place in a direction at right angles to that line. For this purpose the belt is deflected on the tight and slack side by being led past idle pulleys mounted in a frame, and the force is measured which must be applied to keep that frame in a position symmetrical to the line joining the centres of the driving and driven pulleys. It will easily be seen that the proportion between this force and the tension in the belt depends on the amount of deflection we may arrange, and that by making the deflection small a considerable tension and therefore a large amount of energy transmitted can be measured by a comparatively small balancing force. This is certainly an advantage, inasmuch as it enables us to keep the size and weight of the instrument within reasonable limits; but it has this drawback, that any error which may creep into the measurements is greatly magnified.*

It will be interesting to compare the first original form of Hefner-Alteneck's dynamometer with its latest development as used in the competitive trials at recent exhibitions. The original form was first brought to public notice in England by Dr. John Hopkinson in a paper read before the Institution of Mechanical Engineers in April, 1879. In Fig. 36 A is the driving and B the driven pulley; C C are idle pulleys deflecting the belt inwards, as shown. If the motion takes place in the direction of the arrow, the lower side of the belt will be

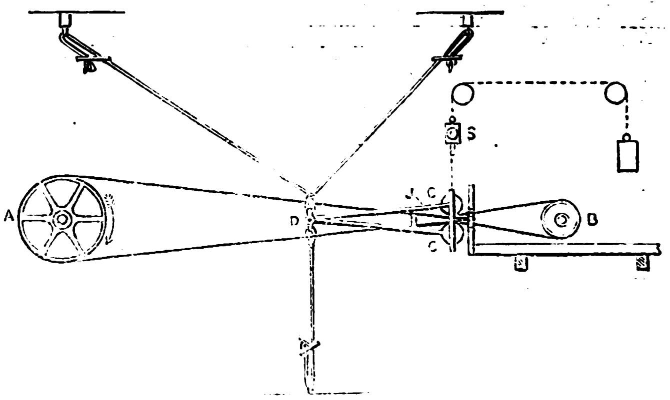

Fig. 36.—Hefner-Alteneck's Dynamometer. Original Arrangement.

tighter than the upper side, and there will be a tendency to displace the idle pulleys, and their supporting frame downwards. To resist this tendency a rope led over snatch blocks and weighted at its end is used. The greater the power transmitted the heavier must be the weight to keep the frame on the centre line A B. It was soon found, however, that the friction of the snatch blocks was objectionable, and a spring balance, S, was therefore inserted in the rope, as shown. The force necessary to keep a pointer on the frame opposite a datum mark was then read off the spring balance. The frame was hinged at the rear on a bar, D, which was provided with eyes, and secured in position by six or eight guy ropes. If we know the dimensions of the pulleys, their distances, and the thickness of the belt, we can calculate the angle of deflection,

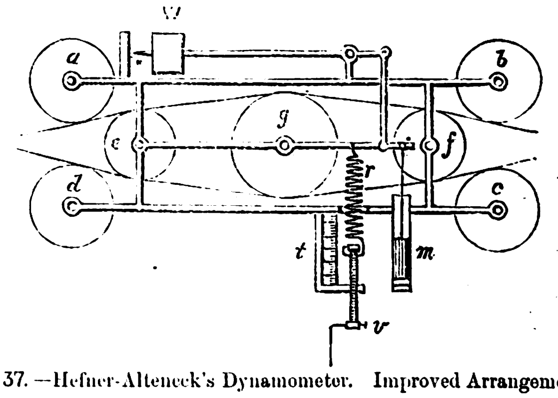

Fig. 37.—Hefner-Alteneck's Dynamometer. Improved Arrangement.

and deduce a formula which gives the difference of tension as a function of these data and the indication of the spring balance. In the hands of a careful experimenter fairly accurate results might be expected even from this primitive arrangement; but the inconvenience of having to rig up the dynamometer for each test anew, and the liability to error where so many measurements have to be taken, are defects which make it unfit for general purposes. In this respect the improved form shown in Fig. 37, and which is also due to

* Compare on this point the official report of the jury on the International Electrical Exhibition at Munich. According to Professor Moriz Schröter these errors became inconveniently large when testing Marcel-Deprez machines for transmission of power.

Digitized by Google

Hefner-Alteneck, is by far preferable. It consists of a double frame, carrying the bearings for six pulleys, *a b c d e* and *f*. The frame can be screwed or clamped at any convenient height to a heavy wooden support, which is placed about midway between the prime mover and the machine to be tested. The belt is led through the pulleys, as shown, and embraces a seventh pulley, *g*, which is, however, not carried by the frame itself, but by a lever hinged at *e*. The weight of this pulley and lever is counterbalanced by a weight, *w*, on a second lever, which also serves as index, showing when the pulley *g* is exactly central within the other pulleys. The tendency of a difference of tension in the two sides of the belt is to displace the middle pulley vertically, and to counteract this tendency a spring, *r*, is provided, which, by means of a handle, *v*, can be tightened to any desired amount, and the strain can be read off on the scale *t*. A dash pot, *m*, is added to reduce jerks and vibrations due to belt joints or other inequalities. The instrument is calibrated by suspending it vertically, and attaching known weights to the bottom ends of two separate belts. The difference of these weights is noted, and also the corresponding tension of the spring. During calibration the frame must be constantly tapped with a wooden mallet, to make the joints and levers work freely, but when at work this precaution is not required, since the high speed at which the seven pulleys revolve causes sufficient tremor to prevent any sticking of the levers.

OLD CABLE STORIES RETOLD.—III.

BY F. C. WEBB.

THE UNARMOURED LINE FROM DOVER TO CAPE GRISNEZ.

"Come, get up, Mr. Webb, here's the 'lectric talegraph in the harbour." Thus I was aroused by Captain F. Bullock's old one-eyed steward on board H.M.S. "Widgeon" in Dover Harbour on the morning of August 25, 1850. I hardly knew then what the "'lectric talegraph" meant, and was soon up and prying about on the quays of Dover Harbour till I found a London tug with a great reel of smooth brown-looking stuff across her deck just abaft the funnel. I was only a visitor on board the "Widgeon," but some help being asked from Captain Bullock, Lieutenant Burstal (now Captain Burstal, secretary to the Thames Conservancy Board) was sent with some dozen men on board the "Goliath" (tug) to render any assistance required, and I accompanied them.

The first attempt at a submarine telegraph across the Straits was about to be made. The wire was simply a copper wire insulated with a single covering of gutta percha to a thickness of about half an inch. It was wound on a reel extending across the deck. A cast-iron reel had at first been supplied, but this was so ponderous and heavy that a spar of wood with cast-iron ends was prepared by the late Mr. W. Reid, who was employed by Mr. Wollaston, the engineer in charge on the work. To sink the line and moor it flat leaden weights with a groove running diagonally across them were prepared, so that they could be easily riveted on to the wire. Half the number had two holes in them, and the other half were cast with projecting studs of a size to fit the holes and project a little through. A blow with a hammer on each projecting stud thus riveted them quickly and securely. Some softened gutta percha was placed in the groove to give the wire better protection from the edges of the metal. For shore end the wire was encased in lead.

We went outside the harbour, and the tug anchored close off the works of the Admiralty Pier, then only just begun. There were on board Mr. Wollaston (in charge), Mr. Crampton (a visitor), Mr. H. Brett, the concessionaire, and some other gentlemen. The lead-covered wire was already down the pier, and the end from the tug was joined on to the primitive shore end in a boat. I can well recollect Mr. William Reid (better known by telegraph engineers of that day as "old Reid") standing up in the boat with a soldering iron in his hand, with which he had done something to the lead-covered wire. As soon as we started there was a difficulty in finding a convenient place for riveting the weights together on. I suggested shipping the hawser-bridge. This was done, and a workman sat astraddle across it and had a good place to rivet the lead weights on. At first we stopped altogether to rivet the weights, but after a little while we collected some slack near the taffrail, and then only slowed down and eased the slack over, during which time the weights were being riveted. There was a break on the drum, and at the stern our men from the "Widgeon" had some wet canvas and held this round the wire. Little Mr. Brett came fussing about our men with such impracticable orders that at last they deliberately entangled him in the loose slack, so that he did not come there again. I have no knowledge of the distances the weights were apart, but probably they numbered about 16 or 20 to the mile. I know that a gentleman (I think a Mr. Wollaston, and relative of Mr. Wollaston, the engineer in charge) gave the time to ease down with a whistle. The ship was then eased, a man ran along with a piece of warm gutta percha, clapped it on the lower weight, the wire was pressed into it, another piece put on top, and the top weight put on, two blows given on the projecting studs, and the weight was handed along as the wire slowly paid out again. On the taffrail was a little wooden roller, but no guide of any kind to keep the line on it.

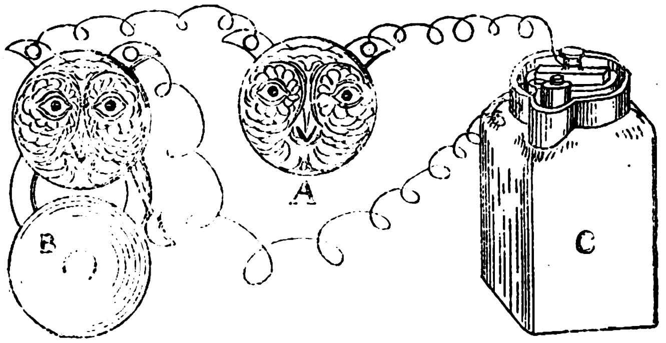
When we got off Cape Grisnez we anchored, and a type printing instrument was put in circuit in the cabin. The instrument began to print off a jumble of letters, and Mr. Brett tore the slip up, although it was a record of the first signals across the Straits. This so incensed Mr. Wollaston that I thought he was going to box Mr. Brett's ears. Being of an archæological turn of mind, I saved a piece and carefully pasted it on paper and labelled it. Captain Bullock requested it of me, and I of course gave it him, and he presented it to the old Duke of Wellington, then staying at Walmer Castle. We joined our own ship, the "Widgeon," soon after this, and did not see the landing of the Grisnez end.

This was my first connection in any way with telegraphy. Of those that were on board Mr. Wollaston, Mr. Crampton, Captain Burstal, Mr. Willoughby Smith, and myself are alive. Mr. Brett died some years ago.

The line was laid to save the concession, which required that telegraphic communication across the Straits should be made before a certain date. The wire answered this purpose, but was cut the day after it was laid by a fisherman, who hooked it up off Cape Grisnez and cut it through with a knife. Dr. Russell, in his work on the Atlantic cable, in alluding to the incident, calls this fisherman a "*pescatore ignobile.*"

ELECTRIC ALARM FOR GREENHOUSES.

Messrs. Jenkins and Co., of Rotherham, are introducing an electric apparatus designed to give warning when the tempera-



Jenkins' Electric Alarm for Greenhouses.

ture of greenhouses and similar places varies from the normal. The apparatus is simple. The case A contains mercury or metal, which expanding or contracting at certain points closes an electric circuit, causing a bell, B, placed in the gardener's house, to ring. The Leclanché cell, C, or cells can be put at any convenient point in the circuit.

THE CITY GUILDS.

The report of the Commission on the City Companies has just been published, and proves to be a document sufficiently thorough, we should imagine, to satisfy even the reforming zeal of those who set the Commission to work. Our own interest in the report, however, is attracted mainly by its incidental mention of the circumstance that the Central Technical Institute, the outcome of the Finsbury Technical Schools, together with University and King's Colleges, have in the course of the inquiry submitted claims to the funds of the City Companies whenever those ancient institutions are disestablished and disendowed. At first sight the applications seem not only premature and unseemly, but in the case of the first named claimant very ungrateful, considering the handsome manner in which it has been treated by the doomed Companies during the very short period it has been in existence. The movement on behalf of technical education has been kept going by the zeal and enlightenment of the City Companies, and but for their liberality active work could never have been begun, or, if begun, would have had to content itself with a very modest career for many years to come. As it is, the endowments of the technical schools are all that could be desired, and there is already a vast sum contributed to the great Central Institute at Kensington, chiefly through the instrumentality of the City Guilds.

A little surprise may be pardoned, therefore, when we see the recipients of such favour now foremost among the vultures who surround the dying carcase of their benefactor. But, on reflection, we come to the conclusion that probably they were put on the scent by the Commissioners, who, to justify their killing the game, would naturally be anxious to show that they could easily dispose of it. In this the Commissioners displayed the true instincts of sport, which but for its trophy, or its bag, would give no satisfaction to anybody. The gentlemen who were set on to hunt down the City Companies have shown a very laudable activity in finding customers for their hares, even before catching them, and the Central Technical Institute is by no means behindhand in offering its services as cook.

It is not our province to offer any opinion upon the political aspects of this scheme of confiscation, except perhaps to gently hint that the turn of the spoilers may some day come to be spoiled. If trade corporations are to be dispossessed of their surplus revenues, why not scientific corporations? They have only to grow rich enough to give good dinners, and the parliamentary axe will then be sharpened for their roots. But that, perhaps, is a remote contingency; not so remote, however, as to afford immunity from verbal criticism of a menacing kind. It is a notable fact, and one that comes handy to illustrate our meaning, that only a few days before the publication of this report an evening contemporary of sound Conservative views fell foul of the Central Technical College itself, on the ground that the whole scheme was a job after the manner of South Kensington, and was framed only to put money into the pockets of certain scientific professors whom it named. We are far from endorsing these reckless and no doubt wholly unfounded statements, but they serve to warn us that in these days science is surrounded with no sacred barriers any more than is trade, and when science gets endowments she must look carefully to her expenditure, or the birds of prey will be upon her.

What we are most anxious about, however, are the uses the surplus revenues of these civic institutions will be put to when distributed. There was certainly one complaint made by the newspaper just referred to with which we cannot help in some degree sympathising. South Kensington is not a neighbourhood where artificers or handicraft flourishes, or is ever likely to flourish, and our contemporary protests with some justice against the seeking of a sumptuous habitation for technical teachers when the object ought to be the finding of needy scholars. This is not a very promising beginning even in its days of comparative poverty. What will its condition be when enriched by the redundant capital of the extinct City Guilds? "Easy come, easy go" is a homely proverb applicable as well to modern institutions as to ancient, and its moral is not without meaning for the younger of those fabrics which are rising on the ruins of the older.

We have before now expressed our regret that some method could not have been found for reviving the original objects and functions of these historic corporations. They originally obtained their privileges as overseers of the trades of London. It is idle to lament their having lost their useful powers in that direction; the times have changed, and we cannot reverse their

Digitized by Google

order even if we would. But there was still, it seems to us, an opening for good work in the regulation and encouragement of skilled handicraft, which none could have undertaken better than the City Trades Guilds. Especially was this the case in respect to the resuscitation of apprenticeship, without which we gravely suspect all technical school teaching will go for very little in improving the great mass of our working artisans. Science might then have gone to the Guilds with greater advantage; the Guilds have instead gone to science, with consequences which we sincerely hope may be satisfactory, but which we cannot altogether look forward to without misgivings.

CORRESPONDENCE.

PRIMARY BATTERIES FOR HOUSE-TO-HOUSE LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR:—In *The Electrician* of July 5th you have published that portion of Mr. Probert's interesting paper on "Primary Batteries for Electric Lighting" which deals with the vital question of the cost at which an electric current can be produced when using a battery as compared with a dynamo electric machine. May I be allowed to demur somewhat to the details of his calculation?

By way of practical illustration, Mr. Probert supposes the case of a house which has to be lighted with 100 incandescent lamps, and, if supplied from a dynamo, requires a steam engine which must develop 12·55 horse-power. He assumes the prime cost of the installation to be £300, the annual interest on which at 4 per cent. is £12, depreciation (10 per cent.) £30, and cost of attendance about £60, so that the total annual cost works out at £147, or £1 9s. 6d. per lamp.

Now, £300 for the prime cost of such an installation is much too low a price. In his book on "The Electric Light in Our Homes" Mr. Hammond states (p. 157) that an installation of the size of his own, where the average number of lamps used is only 66, costs £650, and even this outlay on plant would bring Mr. Probert's figures up to £196, or to within a fraction of £2 per lamp per annum. To obtain an equal amount of light from gas at 3s. per 1,000 cubic feet (burnt in Argand lamps) would cost £180; at 5s. per 1,000 cubic feet it would cost £300.

Proceeding next to a calculation of the cost of producing the current by the oxidation of zinc, Mr. Probert founds his estimate on the theory of the Bunsen battery, using sulphuric acid to "oxidise the zinc" and nitric acid to "depolarise," and he calculates that in order to develop 12·55 electrical horse-power per hour the following minimum expenditure would be incurred:—

	s.	d.
13lb. of zinc at 2½d. per lb.	2	8½
In the zinc cell, 19½lb. of sulphuric acid, at ¾d. per lb.	1	2⅝
In the carbon cell, 8⅝lb. of nitric acid, at 6d. per lb.	4	4
Total per hour	8	3

	£	s.	d.
Thus the cost of materials per annum (1,800 hours) being	£742	10	0
The interest on the prime cost of the battery, at 4 per cent.	5	0	0
And the annual depreciation, at 10 per cent.	12	0	0
The total cost per an. of 100 lamps would be..	£759	10	0

Or at the rate of £7 11s. 8d. per lamp.

Mr. Probert, however, very truly suggests that there are several ways in which this extravagant cost may be reduced, and the possibility of a "cheaper oxidant than sulphuric acid" being used is the point to which I desire specially to address my observations, since that is one of the main distinctions of my battery. He says: "As to the oxidant, or, speaking more generally, the solvent of the positive element of the cell, sulphuric acid has been replaced among other substances by hydrochloric acid, and a battery employing this liquid has been introduced by Mr. Ross."

This is not quite accurately expressed, for I substitute for the sulphuric acid in the zinc cell nothing but water, with so small a quantity of salt dissolved therein that in the estimate of cost it may be neglected, and thus the outlay of 1s. 2⅝d. on sulphuric acid in the zinc cell may disappear altogether from the above estimate.

It is as a substitute for nitric acid in the carbon cell that I introduce the very much cheaper hydrochloric acid, adding thereto a small quantity of my "Eureka," which brings up the cost of the undiluted "depolarising" liquid to about one penny per lb., or ⅙th of the cost of the less powerful nitric acid* of Mr. Probert's estimate; and, having thus reduced the outlay on the liquids which in theory are required in order to produce 12·55 electrical horse-power from 5s. 6⅝d. to 9d., I am able still further to lessen that estimate by adopting Woodhouse and Rawson's "deposited carbon" lamps, because 100 of these lamps (at 333 candles per horse-power) require only six electrical horse-power to produce the light of 2,000 candles.

Theoretically, therefore, Mr. Probert's estimate of 8s. 3d. for the cost per hour of the materials used to produce the current for 100 incandescent lamps of 20 candle-power may with the Ross primary battery be reduced to 1s. 8½d., as follows:—

	s.	d.
Cost of 6·18lb. of zinc for 6 horse-power, at 2½d. per lb.	1	4
Sulphuric acid in zinc cell	0	0
Liquid used in the carbon cell for 6 horse-power	0	4½
Total per hour for 100 lamps	1	8½

And again:

	£	s.	d.
Cost of materials for 1,800 hours, at 1s. 8½d. per hour	£153	15	0
For interest and depreciation, instead of Mr. Probert's £17, I will allow as much as	70	0	0
Total cost per annum of 100 incandescent lamps...	£223	15	0

Or, at the rate of £2 4s. 9d. per lamp per annum.

This is at the rate of 537 pence per lamp for 1,800 hours, but in practice the cost to the user of a battery will no doubt be rather more. Taking it roughly at ½d. per hour per 20 candle lamp, raises the *theoretical* estimate of "cost of materials" for 100 lamps from the before-mentioned 1s. 8d½d. per hour to 3s. 4⅔d. in *practice;* or from £153 15s. to £305 per annum, thus leaving also a margin of profit between the manufacturers' prices and the cost to the consumer.

Should incandescent lamps in the course of time be so improved as to have their efficiency increased to 1,000 candles per horse-power, as is considered "probable" by Dr. J. Hopkinson, it would reduce the cost of the electric light with primary batteries to one-third of this estimate.

Will you permit me, Sir, to add that primary batteries as now constructed are so much less troublesome and less noisy than dynamos; they are so steady and regular in their action, and may be so easily controlled and kept in order by domestic servants, that I have little doubt of their soon coming into general use for house-to-house lighting. The old-fashioned fallacy as to the excessive cost of zinc in producing electric light cannot be adhered to much longer, and it was generally recognised on the occasion of the brilliant *conversazione* given last week at King's College by the President of the Society of Telegraph Engineers and Electricians, when the rooms were lighted by primary batteries of the Holmes and of the Ross types, which stood in the corners in view of all the visitors, to show that they need not occasion any unpleasant smell in a house. The steadiness of the light was in marked superiority to that of the lamps in the hall, which were supplied from a dynamo.

* The chemical combination (combustion) of 1 gramme of zinc with oxygen evolves only 1,306 gramme units of heat, whereas its combination with chlorine evolves 1,547 units.

Digitized by Google

Houses in Mayfair, Belgravia, and South Kensington, &c., ought all to be lighted by primary batteries.

Apologising for the length to which this letter has extended, I remain, Sir, yours, &c., O. C. D. Ross.

21, Austin Friars, E.C.

LIGHTNING CONDUCTORS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have noticed, and read with interest, the articles on lightning conductors that have appeared from time to time in your issues. I beg to draw your attention to the enclosed correspondence, but, before doing so, give you the following particulars :—In the suburbs of this city there is a large brick works; they have on their land two chimney-shafts of about 160ft. in height. They are now erecting a third, and of similar dimensions. All being in a very exposed position, no other tall building or shaft being within a distance of 300 to 400 yards, I wrote as follows :—

"24th June, 1884.

"Messrs. The Stanley Brick and Land Company, Stanley,

"Dear Sirs: On hearing from you I shall be pleased to give you an estimate for erecting a lightning conductor on your new chimney, now building. I need hardly inform you that in an exposed position it is of the utmost importance to have the buildings thoroughly protected.—Yours truly,

"Wilfrid H. Fleming."

"3rd July, 1884.

"The Manager, Stanley Brick Company, Stanley.

"Dear Sir: I wrote you on the 24th ult. respecting lightning conductors for your new shaft, and if not already decided upon shall be pleased to give you an estimate for fixing the same. I called at the office in Crosshall-street, but have been referred back to you.—Yours, &c.

"Wilfrid H. Fleming."

Their reply I enclose, and should be glad to have your opinion on the same. There seems to be no plausible excuse, as the cost is trifling.—Yours, &c.,

Wilfrid H. Fleming.

(Reply.)

"Liverpool, 3rd July, 1884.

"Mr. W. H. Fleming.

"Dear Sir: In reply to your note of to-day's date, the directors have decided not to fit a lightning conductor to our new shaft.—Yours truly,

"Wm. Wethered, pro. Company."

THE CURRENT-CARRYING CAPACITY OF WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Dr. Fleming opens a subject which is most important to all electric light engineers, many of whom, like "Student," look with suspicion on an untried formula. There is one point in your correspondent's letter which does not appear to agree with previous experiments, namely, "that the heat removed from a naked wire is greater by convection than by radiation." It appears to me that in these experiments the amount must be about the same if the temperature does not exceed 50 degrees C. Referring to a paper entitled "Warming Buildings by Steam," which was read at the Institution of Civil Engineers in 1882, the question of radiation is fully gone into as regards the emission of heat from iron pipes. In the discussion which followed Mr. T. H. Blakesley stated that, in accordance with the researches of Dulong and Petit, it appeared that at a low temperature the proportion of heat given out by radiation was greater than that given out by convection, but at about 73 degrees difference (which is, approximately, that between the air and the wires in Dr. Fleming's experiments) the proportion was the same.

As regards the relative heating of the various coils, were they of sufficient length so that the cooling effect of the terminals would be inappreciable? If not, it would, perhaps, account for one metal parting with the heat more rapidly than another, according to its relative conductivity. I pointed out the great influence the cooling effect of terminals has on the melting point of short wires or foils in a previous letter to *The Electrician*. Recent experiments have confirmed this.—Yours, &c. Killingworth Hedges.

Queen Anne's-gate, Westminster, S.W.

ELECTRIC LIGHTING IN MILLS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In the second paragraph of my letter in last week's issue, as to electric lighting, at the end of the paragraph I find I use the expression "considerations of economy and *efficiency*," while I should have said "considerations of economy and *simplicity*."—Yours, &c.,

W. C. Martin.

Commercial-street, Dundee, 3rd July, 1884.

THE HEALTH EXHIBITION.

The following observations are not written for the benefit of those who are familiar with the technicalities of electric lighting, but for those who are interested in knowing something about a subject which is perhaps too often treated in these columns from a scientific point of view. Explain to us as to little children is the request of many sensible people, and we hasten to make the attempt. Unfortunately the subject is one that cannot be fully understood till some knowledge is obtained of it as a whole. It is not necessary to think of the source and the mouth of a river when one stands on its banks at a narrow portion in order to find out why the water rushes onwards with great velocity, raising clouds of foam and spray. We see the water, and perhaps if we could see that which is called the electric current the phenomenon of the electric light would be easier to understand. The rushing water in the narrow river bed is somewhat analogous to the rushing electricity at the point of light. The one causes spray and foam, the other heat and light. In order, however, to have the narrow river bed we must have the river; we must have a source of water—a channel for the water to flow—the action of gravitation causing the water to flow. For the sake of simplicity and on purpose to take advantage in our explanations of analogies that may aid the understanding, we shall speak of a current of electricity just the same as we speak of a stream of water.

In the first instance, let us try and take a rapid glance at the complete system. Imagine a large reservoir of water, and that by means of a steam engine acting on a pump part of the water is raised some distance above the level of the other water and poured into the mouth of a pipe, the other end of the pipe being at the bottom of the reservoir. We all know the water would run down the pipe, and if the pipe happened to have a smaller section at one part than anywhere else the rush through that part would be quicker. Now, with the electric light we have the steam engine driving a dynamo machine which answers to the pump, raising not water but electricity to a higher level, or, as the electricians call it, potential, and putting it into one end of a wire. Like the water through the pipe, we may imagine the electricity going through the wire. In this wire is joined up a piece of something, through which, so to speak, the electricity has to rush faster—like the water through the narrow river bed or the smaller pipe, and in thus rushing faster the electricity causes the material to become very hot; so hot, indeed, that it is rendered incandescent or light giving. A little more may be said of our rushing water. It may be wanted to turn a mill-wheel, and then come questions as to what kind of a wheel, and whether alterations should be made to the channel. In fact when we want the moving water to do work we want as much as possible of it, and so with our electricity. When we ask it to give light or to turn a wheel we want the work done at as small a cost as

Digitized by Google

possible. We want all the electric current to do work and not merely a part of it. If we ask for light we want it economically. Again, it must be pleasant, steady, soft, agreeable. It must be amenable to reason; that is, it must be turned on or off, up or down, without danger, at pleasure. Here, then, is the problem our friends the electricians are asked to solve. Give us in our homes a suitable substitute for gas, which is dangerous, dirty, unhealthy, flickering, and in other ways a disagreeable light. It has its advantages, and whatever you give us we must retain those advantages. Have the electricians solved the problem—can they supersede gas, can they give us an improved light at a fair cost without bringing with it a number of disadvantages which render it practically useless? Visitors to the Health Exhibition can judge for themselves in some measure what the electricians can do, for we can assure them that never in the history of electric lighting has a better opportunity been given for a study of part of the subject. The one part of the question that cannot be studied here is the cost.

It can easily be shown that all parts of the apparatus used must be carefully designed if the result is to be satisfactory. Consider again for a short time the reservoir of water, the engine, pump, and pipe. If we require the same quantity of water to flow through a given portion of the pipe second by second, minute by minute, and hour by hour, it will not do to have your engine now running fast, now slow—it must run with absolute regularity. Nor will it do to allow the pump valves to be in a defective state, sometimes acting well, sometimes badly. The water raised by the pump must not vary second by second, nor must the height to which it is raised, and so on. Remember, we are asking the electric light engineer for a more perfect light, and he must see that his engine, dynamo, lamp, &c., are suitably constructed. The velocity of the water under constant head running through the narrow part of the pipe would vary if the section of the pipe varied; it would also vary if the section remained constant while the head of water varied. Let us take, first, that the section of the pipe is never to vary. What answers to this in electrical matters is called by electricians resistance. So we can see that the electricians must, in order to give the light we want, get hold of some material through which the electricity is to pass that will not alter its resistance. Perfection is perhaps impossible, but the electricians have tried to get as near perfection as possible in two ways. In what they call "arc" lamps they endeavour to keep resistance pretty constant by regulating the distance between two carbon points, through which points the electric current is made to pass. We know that a rapid stream of water rushing along between banks of soft earth tears away the material of which the banks are composed, connecting the banks by a bridge of muddy water; so the electric current rushing along tears off particles of carbon from one point, carries them along, and forms as it were a bridge of torn off particles with the other carbon point. If the carbon is perfectly homogeneous the particles will be torn off pretty equally all round, till the carbon at this extremity assumes the shape of a well sharpened lead pencil. Such a carbon will of course enable the user to get a steadier light than another carbon which is non-homogeneous, and which is torn away more in one part than in another. The opposite carbon under the action of the current should assume a cup-like shape. Now, if it was possible to obtain a perfectly symmetrical cone, and a perfectly symmetrical cup, with the apex and sides of the cone always at the same distance from the bottom and sides of the cup, and with a never-varying bridge of carbon particles between, we might get no variation of resistance so far as this part of the lamp is concerned. Sometimes the carbons are not placed end on with an air space between, but, as in the Jablochkoff and other "candles," are placed parallel, or nearly so, and separated by a layer of plaster of Paris, or similar material. The other plan adopted is to make the current pass through fine filaments of continuous carbon, platinum, iridium or platinum-iridium. Carbon filaments are, however, almost the only ones now used.

Here the electrician meets another difficulty. He can get a beautiful light by using this carbon filament; but under ordinary conditions the carbon filament burns away like a piece of coke in the grate. In order to burn the coke we have to raise its temperature by the use of shavings, wood, or something of the kind. When above a certain temperature the carbon or coke combines with the oxygen of the air, forming a new substance which chemists call carbon dioxide. The same would occur with the carbon filament, so the electricians put it into a little globe from which the air has been withdrawn; in other words, they put the filament into as good a vacuum as they can obtain. There are other evils to be encountered; but we will assume for the moment that we have obtained a fairly good "arc" or "incandescent" lamp. Plenty of both kinds of lamps will be found in the exhibition. The arc lamps are very brilliant, and are used to illumine large spaces. The "incandescent" lamps are more like gas jets, and are used for interior lighting.

Now let us consider for a moment the work of the engineer who designs and builds the engines. His friend and colleague the electrician says, No matter the load on your engines, my dynamos must run with exactly the same number of revolutions per minute, hour in and hour out. My dynamo takes the place of the pump, and the head of electricity must be as constant as the head of water. No matter to you whether the pump is constructed to throw a pint or a gallon at each stroke, or to vary the quantity thrown exactly as the quantity used, the number of strokes of the pump must be constant. The engineer listens to all this, and gets somewhat mixed as to his notions about pumps, dynamos, electricity, and water; but he has one fixed idea—that the number of revolutions of his fly-wheel must remain constant under a varying load.

(TO BE CONTINUED.)

INCANDESCENT LIGHTING.

BY T. H. SEYMOUR HAWKER.

(CONTINUED FROM PAGE 153.)

In any of the modifications of the parallel circuit which circumstances may suggest or practical exigencies render advisable, the resistance of the conductor is the ruling consideration. With a sufficient size of conductor, circuits may be run with fairly good results on any or—as many of the present installations justify us in saying—no particular plan. It is when economy becomes a consideration that *system* and a due recognition of the relative or special advantages which fit the typical methods for particular work become important, enabling a less weight of copper to be employed to produce a good effect.

In the earlier stages of electric lighting (and even in some instances in the present) by far the most common defect was the use of wires of too small section, giving the circuit an uniformly higher resistance, and reducing the efficiency of the circuit.

To get a given effect at the lamps in this case would naturally throw a greater load on engine and dynamo than with a good circuit, and when working with a small margin this has been to blame for many of the failures which have from time to time gladdend the hearts of gas shareholders. Experience is, however, credited with the ability to instruct those who do not possess the mental powers to enable them to guide their conduct by reason, and hence we find that many of this class, having probably had the lesson impressed by a salutary rap on the knuckles, have flown to the other extreme, and waste their copper by blindly pinning their faith to a standard of so many amperes per square millimetre of sectional area. The philosophy of such a scale is more than doubtful, even were it possible to grade the conductor so as to retain the ratio of current to section constant at all parts of the circuit, or even practicable to approximate to this by the use of many different sizes. As, however, we shall see when considering the proportioning of conductors in an example circuit, the conductivity is of greater importance at some points than at others, and in fact different limiting conditions affect the size of cable at different parts.

For these reasons any fixed standard will allow too much copper at some places and insufficient at others.

Digitized by Google

A standard, moreover, seems to tacitly countenance work more by rule of thumb than by scientific investigation and proper special calculation of quantities for each different case.

The general fault introduced by this system is in the right direction, however, and affects the pocket of the installer and not the efficiency of the light.

With the underwired, haphazard circuit this is different, and means have to be taken to remedy the deficiency of copper or its uneconomical distribution.

This can be done by using lamps of higher E.M.F., and increasing the E.M.F. at the terminals, or by reinforcing the existent wires with others of suitable relative section, which can be looped on branch by branch, as shown in Fig. 5, where the added cables are shown dotted, and the existent high resistant circuit in full lines.

The rule to follow in this correction is to add wires of such section as to give when in parallel with the existent leads a

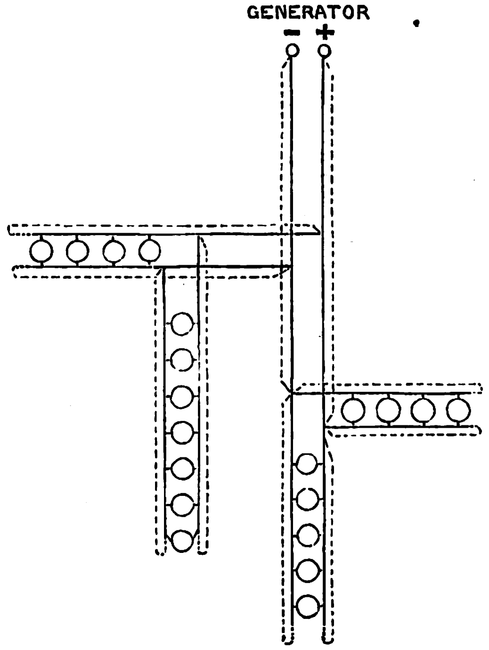

FIG. 5.

conductivity equal to that conductivity required in that portion of the circuit. Thus, if $\frac{1}{R}$ be the required conductivity, and $\frac{1}{r}$ the existing conductivity—in each case the reciprocal of the respective resistances—then the conductivity of the conductor, which must be added in parallel to $\frac{1}{r}$, must be equal to $\frac{1}{r_1} = \frac{1}{R} - \frac{1}{r}$.

The most suitable dimensions for an electric light conductor are determined, generally speaking, by a combination of several ruling conditions, and foremost among those is the increase of temperature which can be safely permitted. While an economical ratio is maintained between the aggregate resistance of the lamps and the resistance of the entire circuit there need be no fear of dangerous heating in any part, but where the section of conductor is otherwise unimportant, as in leads to individual high resistance lamps, the ultimate temperature becomes an important consideration, as it practically limits the economy which may be possible by reducing the weight of copper. Let f = the percentage of heat radiation per unit difference of temperature between a conductor and the surrounding medium expressed as a fraction of entire heat H, contained by the body of mass m, *per unit length*, and specific heat h, at temperature t. Then $H = t\ m\ h$, and the ultimate temperature of the body, if a conductor of resistance R, and surface a, traversed by a current C, will be approximately:—

$$T = \frac{C^2R}{42 \times 10^6 \times m h f a} \text{ (all in C. G. S.).}$$

The constant f is usually taken as = ·00025, but varies considerably with different materials and coverings of various thermal conductivities. The fact that the heat evolved is proportional to the *square* of the current is very important to realise, as it shows that a very small percentage increase of current must have a big effect on the temperature of the conductor. An increase of 41 per cent. will double and 100 per cent. quadruple the heat evolution. If, therefore, we take the safe working current of a cylindrical copper conductor as one half the limiting current, its requisite mass per unit length will be given by the following formula derived from the preceding:—

$$m = C^2R/42 \times 10^6\, h f a t,$$

where t is the limiting temperature in C° of difference from that of the surrounding air or other medium.

This is simple enough to apply in practice if we get the necessary data from any reliable physical treatise; but, unfortunately—at least for the simplicity—the current in a lighting circuit is a most complex function of the E.M.F. at its terminals, and it will be well to consider this matter in detail before proceeding with the methods of determining the sizes of those mains and leads whose resistances are for a given circuit efficiency necessarily too small to allow their heating to be considered. The chief cause of this complication is the variation which occurs in the resistance of both lamps and conductors when a current is passed through them. The variation is in both cases due to, and varies directly as, the heat generated by the flow, which is as we have seen in proportion to the square of current. In the lamp filaments, however, we have the anomalous physical attributes of carbon to contend with, and instead of the almost universal rule of heat *increasing* resistance we find it greatly reduced thereby.

The economical working temperature of a lamp is usually attained when the resistance is reduced to about one half the resistance when cold; but this depends greatly on the "individuality" of the type of lamp used. The luminosity of a lamp is a measure of the temperature of its filament, and is therefore intimately connected with the resistance, and is a very definite function of the cube of the energy evolved therein. We can therefore, by putting L as a measure of absolute luminosity, and Ψ as the ratio of this to the energy cube—C^2R—write:—

$$R_1 = \sqrt[3]{\frac{L}{C^6 \Psi}}$$

In the absence, however, of any absolute system of photometry, this has merely a theoretrical interest, as in practice the lamp resistance R_1 has to be measured directly.

This is best done by a measurement of the E.M.F. at the terminals, when carrying a given current, and a tabulation of a series of such results, with different currents, should be in the possession of every electrician, being invaluable in the calculation of circuit data.

Not only each type, but each size of lamp has a different constant, so a recommendation to experiment on those most in use can alone be given, especially considering the questionable permanency of the lamps at present in the market.

With the conductors the change of resistance is not so great, and can generally be neglected.

In cases of considerable current density, however, the resistance, at a given increase of temperature, becomes important.

CONVERSAZIONE AT KING'S COLLEGE.

At King's College on Thursday week, the 3rd inst., Professor Adams, President of the Society of Telegraph Engineers, gave a *conversazione*, at which many well-known electricians and scientific men were present. Professor Adams received his guests in the entrance hall, the arches of which were illuminated by Edison lamps, of whose performance on this occasion the less said the better. The Wheatstone laboratory was turned into a temporary exhibition of the latest novelties in electrical apparatus. This and the adjoining room were capitally lighted by means of Woodhouse and Rawson 16

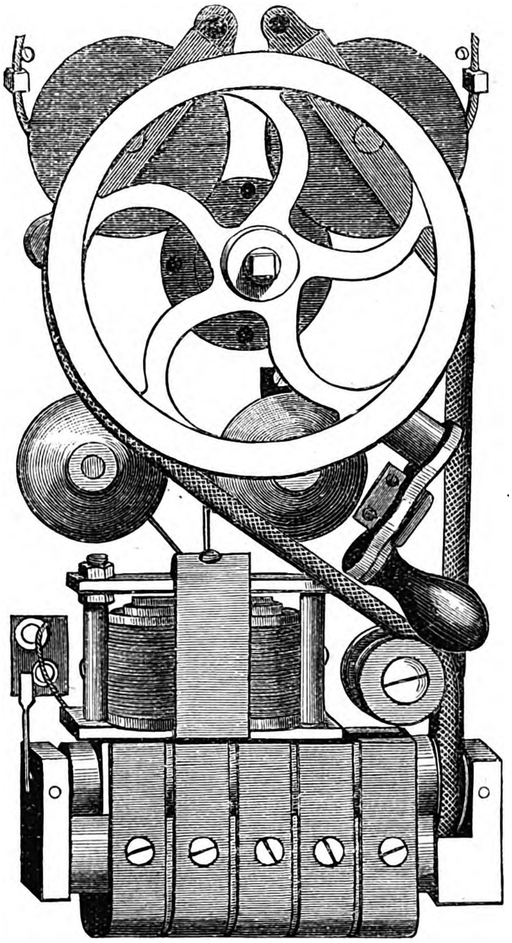
Digitized by Google

candle-power incandescent lamps, the current being supplied by Ross's primary battery. Mr. Ross was present to describe the construction and working of his battery, of which a model was exhibited, and informed us that many of the zincs in the cells supplying the lamps had been in fairly constant use since March, 1883, and that they were only 3-16in. thick to begin with. The museum adjoining the laboratory was also lighted by Swan incandescent lamps fitted up and lent for the occasion by Messrs. Laing, Wharton, and Down, of Holborn Viaduct, E.C., the current in this case being supplied by 23 of Holmes's cells. The number of lamps employed was 28 of 10 candle-power. The light afforded was pleasant and as steady as could be wished. In the laboratory we noticed a working model of the telpher line, which has given rise to so much discussion of late. Professors Ayrton and Perry exhibited their numerous meters and a foot resistance box, which they have recently brought out for use with their motor. By pressing the box with the foot the resistance of the carbon plates inside is decreased, and on releasing the pressure the resistance is not only increased, but the carbon plates are shaken up by a spring, and the freedom of contact restored, which the mere elasticity of the carbons will not do. The application of this box to motors, and its utility for controlling their working, are obvious. Messrs. Crompton and Co. showed drawings of their electric lighting station at Victoria, specimens of the plates used in Dr. Frankland's accumulators, current and potential indicators, and the Crompton-Crabbe arc lamp. Mr. Gisbert Kapp showed his dynamometer for testing small motors, and an energy indicator. We also noticed a collection of testing apparatus made by Messrs. Elliott Brothers, who also showed a table lamp (incandescent) worked by Skrivanon cells placed inside the base of the lamp, Mr. Hedges' cut-outs, apparatus by Siemens Brothers, Captain Cardew's voltmeter, &c., &c. Mr. A. J. Frost showed a new electrical clock, in which the pendulum is entirely controlled and actuated by electricity. The principal novelty about this is the manner in which contact is made, the circuit being completed for an instant once in every 12 seconds. We may mention that one of these clocks is exhibited at the Health Exhibition, and has been going since October last without a stop. Mr. Latimer Clark exhibited a photograph of Edward Davey, whose name Mr. Fahie so prominently brought before our readers a short time since. It is a recent one, and was brought to this country by Mr. Eaton (Dr. Davey's son-in-law), who was at the *conversazione.* In the upper corridor, outside the laboratory, Mr. J. H. Greenhill showed his new dynamo, which he described in his paper on mill lighting, published in our issue of June 28th; and Messrs. Clark, Muirhead, and Co., exhibited resistance coils and apparatus, showing the effect of retardation on an artificial cable, equal to about 8,000 miles of the Bennett-Mackay cable, at present being laid for the Commercial Cable Company. The effect of retardation, under the circumstances, was very marked, the current taking about three seconds to traverse the entire line to show a signal at the distant end. The total electrostatic capacity of the cable was about 2,400 microfarads, and the total resistance about 1,200 ohms. In addition to this exhibit there were several instruments connected with the making of the Muirhead duplex system, as also Mance's new system of testing apparatus, which has been specially designed for fault testing on cables. The apparatus exhibited was manufactured by Latimer Clark, Muirhead, and Co., of Westminster. The resistance coils and condensers are probably by this time on their way to the Irish and American stations of the Bennett-Mackay cable, where they are to be used for duplexing the cable on Muirhead's system. It was curious to turn from these latest advances in cable working and to study Wheatstone's plans for laying a cable between England and France which he drew out in October, 1840. In the Metallurgical Department Professor Huntington showed the application of electro-metallurgy to the analytical determination of copper. We must not forget to mention the interesting exhibit of Mr. W. H. Preece, consisting of Dvorak's acoustic apparatus and a new photometer, the joint production of himself and Mr. A. P. Trotter. A description of Dvorak's apparatus will be found in our issue of September 15, 1883, together with illustrations. The guests did not separate till a late hour, having, thanks to Professor Adams and his scientific *confrères,* spent a most enjoyable evening.

ELECTRICAL TESTING APPARATUS.

At the *conversazione* of the Society of Telegraph Engineers and Electricians Mr. Killingworth Hedges exhibited a very convenient little apparatus for testing the insulation of an electrical circuit. We give a sketch of the apparatus. It is the invention of Mr. Woodbury, an American gentleman intimately connected with the question of fire insurance.

It consists of a Siemens armature, wound with fine wire, and rotating between the poles of a series of permanent magnets. There is no commutator, and the alternating currents pass through the coils of an electro-magnet, which causes oscillation in a small bar magnet, pivoted at its centre, and carrying a striker placed between two bells.



Killingworth Hedges' Electrical Testing Apparatus.

The gear for putting the armature in motion is, as shown, very compact and simple. Connected in circuit are two steel tapes on rollers, 35ft. in length, and provided with steel clamping jaws at their ends. The driving wheel, as well as the tape reels, are worked by means of the same crank, which, when not in use, reposes snugly in the position shown. The whole is contained in an ebonite case, $8\frac{1}{2}$in. × 4in. × $1\frac{3}{4}$in. in dimensions. The bells will ring through an external resistance of 7,000 ohms when the crank is turned 200 times a minute. The mode of using the instrument is to clip some conductor leading to the earth, such as the stop-cock of a gas jet, with the end of one of the steel tapes, and to attach the others to the electric circuit. When the resistance of the insulation between the system and the earth is less than 7,000 ohms the bells will ring. At less speeds the limit is proportionally less. This instrument requires no skill for its use. Its simplicity recommends it strongly for the purposes of testing, for which it was designed.

ARTIFICIAL LIGHTING.*

In early times but a small fraction of our forefathers' lives was spent under artificial light. They rose with the sun and lay down to rest shortly after sunset. During the long winter evenings they sat round the fire telling stories and singing songs of love and war; the fire light was sufficient for them, except occasionally during grand feasts and carousals, when their halls were lighted by pine wood torches or blazing cressets. But, as a rule, after sunset they lived in semi-darkness.

From that early period, as man has advanced in civilisation, in the thirst for knowledge derived from books, and in following the gentler pursuits which demand an indoor life, there has been a steady increase in that fraction of our lives which is spent under light other than that of the sun. But the improvement in the quality of the artificial light has been very slow. The ruddy lights and picturesque shadows so faithfully handed on to us by Rembrandt's pictures show us very graphically what our poets have called "the dim glimmer of the taper" of those days. A few years before the introduction of gas Argand, by his improvements in the burners of oil lamps, enabled our fathers to see for the first time a comparatively white light, but as far as the matter we to-day propose to discuss is concerned, viz., the effect of artificial lighting, and more particular electric lighting, on our health, we need only consider the reign of artificial light as it commenced with the general use of gas and petroleum, for then and then only could it be said to affect our health.

Prior to the introduction of the electric light we have been accustomed to consider hours spent under artificial light as hours during which all conditions are less favourable to perfect health than they would be during daylight. Can we now hope to ameliorate this condition of things through the agency of electricity? Before we can discuss this question I must point out to you the chief differences which exist between hours of work or recreation spent in daylight and under artificial light. In the former case we live in abundance of light. The sunlight itself exercises a subtle influence on our bodies; that mixture of heating and chemical rays which when analysed form the solar spectrum, and combined form the pure white light of daylight, is needed to enable all animal and vegetable organisms to flourish in the fullest conditions of healthful life.

In nearly all cases when the sun is up the functions of life are in the state of fullest activity, and when it sets they sink into comparative repose. In daylight life wakes, in darkness life sleeps. In addition to the abundance of pure white light, the heat attending sunlight is only that necessary for health. The air remains unvitiated, except by our own breathing. On the other hand, when working under artificial light, we have these conditions all altered in degree:

1st, we have an insufficient light; as a scale of lighting by gas or by electricity which would be pronounced excessive at night time is still far inferior to average daylight.

2nd. All artificial lights, whether produced by combustion, as in the case of candles, oil, gas, and petroleum, or by the incandescense of a conductor by the means of electricity, produce heat; this heat, in proportion with the light afforded, is enormously in excess of the heat given by sunlight. Electricity, as you will see hereafter, is far the best in this respect, but even it is inferior to sunlight.

3rd. All these same illuminants, excepting electricity, contaminate the air, and load it with carbonic acid, sulphur, and other compounds—all injurious to the health and to the general comfort of the body.

It will be convenient to consider the effects—first, on our health generally; second, on our eyesight in particular. I have already called your attention to the fact that that proportion of coloured rays which when combined form white sunlight is that best suited to healthy life. It is necessary for that sufficient and proper stimulus to the organic changes which go on in our bodies, and which we call a state of good health. The various artificial lights differ very widely from sunlight in this respect, that they are all more or less deficient in the rays at the violet end of the spectrum, commonly called the actinic rays, and which most probably exercise a very powerful effect on the human body. It is the want of a due portion of these violet rays which makes all artificial light so yellow. Even the light of the electric arc, which is richer in these rays than any other, is still on the yellow side of sunlight. The incandescent electric light is next best in this respect; next in order comes gas, petroleum, and the various oil lamps. No doubt some of you will challenge my statement that the electric arc is yellow. It has always been called a cold blue light. It is not so; it is only by comparison with the yellower light of gas or with the incandescent lamps that it appears blue; when compared with the sunlight reflected from a white cloud it will be seen to be distinctly yellow in tinge, but still both classes of electric light are far superior to all others in nearest approaching the white light of daylight, and thus satisfying the actinic action which our bodies demand.

Turning now to the comparative heating and air vitiating properties of artificial lights which we shall find it convenient to take together, I have here a table (Table A) prepared by Dr. Meymott Tidy, which shows the oxygen consumed, the carbonic acid produced, the air vitiated and the heat produced by the combustion of certain bodies burned so as to give the light of twelve standard candles, to which Mr. R. Hammond has added the heat produced by a 12-candle incandescent electric lamp.

Table A showing the oxygen consumed, the carbonic acid produced, and the air vitiated, by the combustion of certain bodies burnt so as to give the light of 12 standard sperm candles, each candle burning at the rate of 120 grains per hour:—

Burnt to give light of 12 candles, equal to 120 grains per hour.	Cubic feet of oxygen consumed	Cubic feet of air consumed	Cubic feet of carbonic acid produced	Cubic feet of air vitiated	Heat produced in lbs. of water raised 10°F.
Cannel Gas.........	3·30	16·50	2·01	217·50	195·0
Common Gas	5·45	17·25	3·21	348·25	278·6
Sperm Oil	4·75	23·75	3·33	356·75	233·5
Benzole	4·46	22·30	3·54	376·30	232·6
Paraffin	6·81	34·05	4·50	484·05	361·9
Camphine	6·65	33·25	4·77	510·25	325·1
Sperm Candles ...	7·57	37·85	5·77	614·85	351·7
Wax	8·41	42·05	5·90	632·25	383·1
Stearic...............	8·82	44·10	6·25	669·10	374 7
Tallow...............	12·00	60·00	8·73	933·00	505·4
Electric Light ...	none	none	none	none	13·8

From these figures you will see that the air of a room lighted by gas is heated twenty times as much as if it were lighted to an equal extent by incandescent electric lamps. When arc lamps are used the comparison is still more in favour of electricity. You will be surprised to see from the table that our old friend the tallow candle, and even the wax candle, is far worse than gas in the proportion of air vitiated and heat produced, and you will be disposed to disbelieve it, but the fact is that so long as candles were used light was so expensive that we were obliged to be content with little of it; in fact, we lived in a state of semi-darkness, and in this way we evaded the trouble. It is only since the general introduction of gas and petroleum that we have found what an evil it is.

It is not unusual, in fact we almost always find the upper stratum of air of the rooms in which we live heated to 120 degrees after the gas has been lighted for a few hours. We have grown accustomed to this state of things, and are not surprised that when we take the library ladder to get a book from the upper shelf we find our head and shoulders plunged in a temperature like that of a furnace, producing giddiness and general malaise. If you look again at the table you will see that each gas burner that we use consumes more oxygen and gives off more carbonic acid, and otherwise unfits more air for breathing, than one human being, and it is this excessive heating and air vitiation combined which are the main causes of the injury to the health from working long hours in artificial light. I could go on for a long time giving instances of the fearful state of the atmosphere of our large public buildings as well as of our private homes after the gas has been lighted for a few hours, but this paper is not intended as an onslaught on gas; moreover these ills are so well known to nearly all of

* Lecture delivered at the Health Exhibition by R. E. B. Crompton, Esq.

Digitized by Google

you that I need not bring them more prominently before you. I will only take one instance, viz., that of the Birmingham Town Hall, which has been lighted alternately by gas and electricity.

During the grand Birmingham Musical Festival, which was held in that hall two years ago, some careful experiments were made to show how the orchestra and audience in the hall were affected by the two kinds of lighting. The gas lighting was in the form of several huge pendants suspended down the centre of the hall. The electric lighting was in the form of clusters of lights placed on large brackets projecting from the side walls, with two central pendants spaced between the gas pendants. The candle-power given by the electric light was about 50 per cent. in excess of that given by the gas light, the degree of illumination by electricity was consequently very brilliant.

It was found that when the gas was used the temperature near the ceiling rose from 60 degrees to 100 degrees after three hours' lighting. The heating effect of the gas was, therefore, the same as if 4,230 persons had been added to the full audience and orchestra of 3,100. Similarly the vitiation of the air by carbonic acid was equal to that given off by the breathing of 3,600 additional persons added to the above audience of 3,100. But on evenings when the electric light was used the temperature only rose one-and-a-half degrees during a seven hours' trial, and the air, of course, was only vitiated by the breathing of the audience. The further experiment was tried of giving to every member composing the large orchestra a printed paper of questions asking him how the new mode of lighting affected him or her personally, and I have here 265 replies to those questions. They are very interesting. I will read a very few of them out to you.* From them you learn that without exception the comfort and general well-being of this large orchestra was increased enormously by the use of the new illuminant, and it is reasonable to suppose that the comfort of the audience was increased in an equal degree. I must here add that I have to thank Mr. Henry Lea, of Birmingham, who conducted these experiments, for kindly allowing me the use of his papers. Now, we all of us know that the times when we suffer most from the effect of artificial light is in crowded places of public amusement, which are at the same time brilliantly lighted. Many of us are unable to go to the theatre or to attend evening performances of any kind, as the intense headache which invariably attends or follows our stay in such places entirely prevents them. This headache we commonly say is inseparable from the heat and glare of the gas. Now, this phrase is not strictly correct. It is, no doubt, due to the heat of the gas and its air-vitiating properties, but when we use the word glare I believe we refer to the effect the gas light has upon our heads, and which effect is not due to excess of light. On the contrary, I believe if a far greater amount of light be given by the electric light without the heating and air vitiation being present such headache is never produced, although some of the more tender headed amongst us will at first complain of the glare because they are habituated to associate plenty of light with great heat, great air vitiation, and other evils.

Indeed, so long have we been accustomed to closely associate brilliant artificial light with headache and glare, that we who are introducing electric light are most cautious not to give the full quantity of light which we could afford to give, and which would afford the greatest rest to the eye and greatest bodily comfort. I now come to the effect that light has upon the temperament. If we try the experiment in an assemblage of people of gently decreasing the lighting of the room, it will be found that the spirits of every one will be depressed just as the light is depressed, and, *vice versâ*, their spirits will be raised just as the light is raised. I have many times when conducting experiments of electric lighting on a large scale noticed this fact, and I have been led to the conclusion *that during hours of waking every person is benefited by increase of light up to the extent of full sunlight*, providing that this high degree of lighting is not attended by heat and by air vitiation; and I must add that the source of light must not be from one or two brilliant points only, but it must be well distributed and not such as to cause dark deep shadows.

This leads me on to the subject of the effects on the eyesight of the electric light as compared with other lights. *Healthy eyesight demands a plentiful supply of light. It is the greatest mistake to suppose that a state of semi darkness is good for our eyes*, unless they are defective, or recovering from the effects of past injury or disease. Whoever saw a painter, engraver, printer, watch maker, or indeed anyone the quality of whose work depends on the excellence of his eyesight, who did not desire a flood of pure white light thrown on to his work. I think I have the authority of oculists when I say that 19-20ths of the diseases of the eyes arise from working the eyesight long hours with insufficient light. Again, another great cause of injury to eyesight is the unsteadiness of most artificial lights. Much improvement has been made in the light of gas during the last few years by the introduction of argand burners, and globes for the flat gas burners having much larger lower openings, so that the dancing and flickering batswing burner of five years ago is not now common in a good house. But even the steadiest of the modern gas burners is extremely unsteady as compared with the light of the incandescent electric lamp. Those of you who have been to the Savoy Theatre will have noticed the effects of the lights behind the scenes on the scenery itself. The light is so absolutely steady that it is comparable to sunlight. Hitherto I have said nothing as to the comparative excellence of the two forms of electric light, viz., the electric arc and the incan-

---

* *The following are some of the answers to Mr. Crompton's questions to the band and chorus:—*

Well lighted, the atmosphere of the room greatly improved, and the equal temperature of the whole building has greatly diminished the risk of taking cold from the draughts in entrance and exit.

Much more pleasant than on any other occasion, in fact I never saw a more brilliant light in any hall or concert room in my life. It is a great success, I should imagine.

Well lighted, very much cooler, thus allowing *us* to warm to our work by our own exertions, and also to cool down by resting. A general satisfaction is expressed at the improvement of the comforts of the workers.

At a comfortable, even temperature the light has not afflicted me in the least, although I sit in between four dozen, and on a line to the side gallery lights. The gas used to make me dim.

I, as a member of the Festival Choral Society, think your improved light is a source of great pleasure to those of us that have to occupy the orchestra so often during the concert season.

I have never been on the orchestra before this Festival, but I found the part of the orchestra I occupied was as cool as the floor of any previous concert that I have attended in this or the Wolverhampton Hall.

Cooler and fresher, likewise the violin strings of my own instrument have not been subjected to variation in pitch or otherwise, as is often the case with gas, and think this is important on such occasions when a cool atmosphere is an acquisition to a body of instrumentalists.

Lower in temperature, could see music books better. Freedom from oppressiveness—attended six previous Festivals, someone has fainted. I believe this has not happened this time.

Very cool as regards temperature compared with the temperature when gas has been used to light the orchestra. Instruments have been better in tune with organ. Light excellent.

Very much cooler than on former occasions, and free from that nasty gaseous vapour that made breathing difficult, and parched the throat and injured the voice.

Very much cooler than is usually the case with gas. The light is very pleasant, being a cool white light, not trying to the eyes, always keeping the same colour, never jumping as I have found the case with other electric lights.

Exceedingly cool and agreeable. Certainly one of the most pleasing reminiscences of the 1882 Festival will be the advantages of your electric light.

Delightfully cool, and at the close of the performance but very slightly different in temperature than at the beginning. It is vastly superior to the old system of lighting by gas.

Brilliantly and equally lighted; whilst from my elevated position on the uppermost seat by the side of the organ, had the hall been lit by gas the heat would have been simply unbearable.

Deliciously cool and comfortable, no comparison with any preceding Festival, the heat at the end of the evening being scarcely greater than at the beginning. There has not been one case of fainting near me.

Remarkably cool; in fact the change from the shifting atmosphere under ordinary circumstances is wonderful. I sincerely hope that arrangements can be made to secure this lighting as a permanency.

Much more comfortable in consequence of the substitution of the electric light for gas; it has been but very little warmer for the evening performances with the light than for the morning performance. I have sung in all the principal halls in London (including Royal Albert Hall, Kensington,) and have always found the orchestra quite unbearable soon after lighting the gas. I have pleasure in speaking most favourably of your light, and the comforts in every respect attending it.

Digitized by Google

descent lamp. Both have their proper places. The arc light, which is the whitest in colour and most economical to produce, is not so steady as the incandescent lamp. It is therefore unsuitable for indoor use or for reading by, or for such occupations as require the maximum of steadiness. But it is well suited for the lighting of large buildings and public places. I am unaware if any experiments have been made as to the effects of brilliant arc lighting on the eyesight of men who have to work night shifts, as although the opinion of the workmen who have to work under it is unanimous in its favour, yet that opinion is more based on their personal convenience, due to their being able to carry on their work with facility almost equal to that given by daylight than with special regard to their health. The large sorting rooms at the General Post Office at Glasgow have been for a long time lighted by the arc light, and with a most beneficial result to the health and eyesight of the letter sorters and telegraph clerks. The former occupation is one which tries the eyesight very severely. The public generally does not know how the habit of writing the addresses on envelopes with pale ink and blotting it off rapidly before it has time to darken tries the eyesight of the Post Office letter sorters. So long as gas is used a powerful burner has to be brought very close to the head of the sorter, and under such conditions the eyesight fails at an early age. At Glasgow Post Office I am able to boast that by the introduction of the electric light I enabled many of the more aged sorters who were commencing to use spectacles to do without them—and even I put back the clock of time, in enabling several who had used them for some years to discontinue them. I am aware that it has been alleged by the opponents of the electric light, whether interested or otherwise, that in many cases the intensity of the light has injured eye sight. I do not think any such cases can be substantiated. Many of us who are in the habit of experimenting with powerful arc lamps have had our eye lids temporarily affected by incautious exposure at too short a distance. Again, over and over I met with the complaint that if I stare at an arc lamp for a long time it will make my eyes ache; the obvious retort being why should you stare at the light? If you do the same with the sun you will be equally inconvenienced. Before such an audience as this, which is, of course, familiar with the beautiful electric lighting in the Health Exhibition itself, it is useless for me to enlarge on the many conditions of the electric light as it indirectly affects health. I may only name the many additional pleasures of the eye we get from its use. Our flowers in our rooms do not fade away, and are seen in their true colours. Our pictures or all coloured objects are seen to better advantage. I may mention one thing which would not generally occur to you, that in London certainly an electric-lighted house can be cleaned properly in winter. You may smile at this, but I assure you that the advantage of being able to turn a flood of light into your drawing rooms and dining rooms at six o'clock on a winter's morning, and this without taking away the freshness of the air, so that the whole of the cleaning can be finished as thoroughly as if done by daylight before the family comes down to breakfast, is one that must be experienced before it can be thoroughly appreciated. Again, the advantage to the health of our children is simply inestimable. No night lights, matches left about, or gas turned down low are required. A child six years old can be trusted to press a button and so turn the light off or on; the lamps being high and out of reach are not easily broken or over-turned, and the air of the children's nursery, even if the light be kept burning the night through, remains pure throughout. Another indirect advantage due to the absence of heat is that it is comparatively easy to thoroughly ventilate and cool during the hot weather a room lighted by the electric light. The heat of gas placed high in the room causes such intense draughts when the windows are open that the discomforts and dangers of the draughts are almost worse than the discomfiture from the heat and vitiated air, whereas in an electric lighted room there is no difficulty in opening wide all the windows, the draughts produced being so gentle as to hardly be felt.

[We are sorry to be unable to find room for the discussion on this paper.—Ed. *E.*]

EXPERIMENTS ON THE PASSAGE OF ELECTRICITY THROUGH GASES.

SKETCH OF A THEORY.*

The passage of electricity through gases has of late years become a very favourite subject for experimental investigation. A large number of facts have thus been accumulated, and it becomes of importance to see whether these facts throw any light on the theoretical notions which we have based on other branches of electrical inquiry.

If we have two bodies at a different electrical potential separated by a layer of air, we might imagine the air in contact with the bodies to become electrified, then move on, impelled by the electric forces, and re-establish equilibrium by giving up their charges. The passage of electricity through gases would then be similar to the diffusion of heat. But, however natural such a view would be, it is impossible to maintain it in the face of experimental facts. The experiments which I shall bring before you to-day seem to me to support, on the contrary, the idea that the passage of electricity through a gas resembles the phenomenon studied by Helmholtz under the name of electrolytic convection.

I shall avoid as much as possible all suppositions and hypotheses, which cannot be put to the test of experiment; but it seems necessary to start with some assumption in order to avoid too great a vagueness in the subsequent explanations. The assumption which I shall make is this: In a gas the passage of electricity from one molecule to another is always accompanied by an interchange of the atoms composing the molecule. I shall also try to prove that many facts are easily explained by the assumption that the molecules are broken up at the negative pole.

If, in a vacuum-tube of the ordinary form, the discharge is passed at a pressure of about one millimetre, a luminosity is seen round the negative pole which is called the negative glow. A luminous tongue projects from the end of the positive pole, which I shall call the positive part of the discharge, without meaning to imply that it is charged with positive electricity. The positive part of the discharge and the negative glow are separated by a non-luminous space, which I shall call "the dark interval." The glow itself is divided into three layers, the thickness of which increases with decreasing density. Closely surrounding the electrode itself, we have in the first place a luminous layer, which on new electrodes is of a golden colour. The spectroscope shows the presence of sodium and hydrogen; the sodium is due to foreign matter deposited on the electrode, and the hydrogen is expelled by the action of the heat out of the electrode by which it had been absorbed. When the electrodes have been in use for some time the golden colour disappears, and the spectrum belonging to the gas used is seen. The second layer is known by the name of the dark space. The third layer is the glow proper.

The theory which I shall endeavour to establish is this: That within the first layer the gaseous molecules are decomposed, that their negative parts are projected with great velocity through the dark space, that this velocity is gradually reduced by impacts within the glow, and that in the positive part of discharge the discharge takes place by diffusion except when stratifications appear.

According to the kinetic theory of gases, the molecule of mercury vapour consists of a single atom, which is incapable of vibration. Mercury has a very brilliant spectrum, which proves that the theory is incomplete in some important point. It is well known, on the other hand, that the theoretical conclusion receives support from the fact that the vapour density of mercury vapour is anomalous. If, as is generally supposed, the molecule of the majority of gases contains two atoms, that of mercury can only contain one. If an essential part of the glow discharge is due to the breaking up of the molecules, we might expect mercury vapour to present other and much simpler phenomena than the gases with which we are

* Abstract of the Bakerian Lecture. Read before the Royal Society, June 19, 1884, by Prof. Schuster, Ph.D., F.R.S.

Digitized by Google

generally accustomed to work. *This, indeed, is the case; for I find that, if the mercury vapour is sufficiently free from air, the discharge through it shows no negative glow, no dark spaces, and no stratifications.* At the ordinary temperature the spark does not pass through mercury vapour; but if a tube free of air, but containing mercury vapour, is heated, the discharge passes always in a continuous stream of light. It is not always quite symmetrical with respect to the two poles, and a very curious tendency of the spark is noticed to pass at the negative pole rather from the glass out of which the electrode protrudes than from the metallic electrode itself. A brilliant sodium spectrum then appears at the point from which the spark sets out. Whenever small traces of air remain, stratifications are very apt to appear, as a mixture of air and mercury gives fine stratifications, but I have never noticed them after sufficient removal of the air.

I now pass to the description of an experiment which seems to me to be only capable of explanation by the views brought forward in this paper, and I should like, therefore, to consider them as crucial experiments, which have to be explained by any true theory of the discharge. As negative electrode, I use an aluminium cylinder of 5·5 cm. internal diameter and 8 cm. long. A long aluminium wire running parallel to the axis of the cylinder at a distance of about an inch formed the positive electrode. On exhaustion, the discharge at first passes as a spark in the ordinary way, but as the pressure decreases the glow gradually surrounds the whole cylinder, *with the exception of a dark strip about 2 or 3 cm. in width, directly opposite the positive wire.* The positive electrode seems, therefore, to repel the negative glow.

The following seems to me a plausible explanation of the phenomenon which I have just described. The rapid fall of potential which is observed on crossing the negative electrode suggests at once, independently of any theory that we have to deal with, the action of a condenser, for we know that no statical charge can produce a finite difference of potential at the electrode, while a double layer will produce a discontinuity. Although it may not be proved that an absolute discontinuity of potential exists at the cathode, it is yet certain that a very rapid fall occurs at that place. This is all that is necessary for the argument.

We recognise such a double layer in the case of electrolytes, but there is an essential difference in the thickness of the layer within which we must imagine that condenser action to take place. In the liquids that thickness must be very small, as is shown by the intensity of the observed polarisation currents. The positively electrified matter in every case is kept against the negative surface by a joint action of electrical and chemical forces, for it has been shown by Helmholtz that only thus can we explain a difference of potential between two bodies. It is the chemical forces which keep the electricities asunder. The gaseous molecules or atoms, however subject to their mutual encounters, and always having certain velocities, will tend to leave the surface. They are kept near the surface, however, by the electrical forces.

Suppose, now, that a positive electrode is placed near such a condenser. The resistance of the gas is so much greater than that of the metal electrode that we shall assume the whole electrode to be of the same potential. The lines of force will then cut the surface at right angles, and could we assume the condenser to be infinitely thin, there would only be a normal force acting on its particles; but as the lines of force are curved, the particles not in immediate contact with the surface are acted on by a tangential force which will tend to drive them away from the positive electrode. As a steady state will only be possible when the total force is normal throughout the condenser, we arrive at the condition for the steady state that within the condenser the fall of potential must be the same for equal distances measured along the normal to the surface.

Experimental evidence speaks strongly in favour of such a conclusion. If, for instance, a thin wire is used as electrode, it is well known that the tension at the end of the wire before discharge is very much larger than anywhere else. At high pressures the discharge passes indeed from the end of the wire, but as the exhaustion proceeds, the glow gradually covers the whole wire, and the same amount of electricity flows out of equal areas situated anywhere on the wire, for the dark space which alters its width with the intensity of current is everywhere the same; this implies that the fall of potential per unit distance is the same all over the wire.

Hitherto we have only assumed a certain number of particles positively electrified in the immediate neighbourhood of the negative electrode, and we have left it altogether undecided what these particles are. But if we consider now the fact that the glow does not appear opposite the positive electrode—that is to say, that while the fall of potential is the same all over the surface the flow is stronger at some places than at others, we are driven to the conclusion that the flow does not altogether depend on the fall of potential, and we must again look for an explanation in the chemical as well as the electric forces. Wherever the fall of potential is chiefly produced by the presence of the positively electrified particles, which I now assume to be the decomposed molecules of the gas, these will help by their chemical action to decompose other molecules. Opposite the positive pole the fall of potential is principally due to nearness of that electrode; chemical forces are absent, and the molecules will not be decomposed, This is, I believe, the explanation of the dark area. And it brings with it the explanation of a large quantity of other facts, as, for instance, the one which has been so long observed and well established, that once a current is set up in the gas it requires a much smaller electromotive force to keep it going. For the discharge, according to us, will generally be introduced by a spark which must give the first supply of decomposed molecules before the continuous glow discharge can establish itself.

I may for the sake of clearness once more mention shortly the principal points of the argument.

The rapid fall of potential in the neighbourhood of the negative electrode renders the presence of positively electrified particles in its neighbourhood necessary.

If the distance through which the condenser action takes place is sensible, the positively electrified particles will be acted upon by a neighbouring positive electrode.

A steady state will be established in which the fall of potential along the normal from the surface will be everywhere the same.

As, however, the flow is stronger away from the positive electrode, we must conclude that other forces besides electrical forces determine the flow.

It is natural to assume that these are chemical forces; that, in other words, the positively electrified particles are the decomposed molecules, which by their presence assist the decomposition of others, and therefore the formation of the current.

Unless a flaw is detected in this line of argument, I think that the conclusion must be granted, namely, that the decomposition of the molecules at the negative electrode is essential to the formation of the glow discharge. This is really all that I endeavour to support in this paper. The rest can only be settled by further experiments. And amongst the rest I count also the primary cause which originally produces the decomposition of molecules at one pole rather than at another. It is possibly due to an electromotive force of contact between the gas and the electrodes which tends to make the gas electronegative.

The gaseous molecules, then, according to our theory are decomposed at the negative pole. Their negative constituents can follow the electric action, and as the fall of potential in the immediate neighbourhood of the pole is very rapid, the atoms will leave the pole with considerable velocity. That the region of the dark space is filled with matter projected from the negative pole follows almost conclusively from the experiments of Goldstein and Crookes, and is also shown in a most striking way by an experiment due to Hittorf. If a tube contains two parallel wire electrodes at a distance of say a quarter of an inch, the discharge will at high pressure pass in the usual way from electrode to electrode, but at a very low pressures the discharge from the positive pole goes away from the negative. The results can be shortly expressed by saying that, as far as the positive pole is concerned, the inner boundary of the dark space forms the negative electrode. If the dark space is small

Digitized by Google

and does not reach the positive pole, the discharge passes from the latter towards the negative pole, but as soon as the dark space extends beyond the positive pole, the positive part of the discharge goes towards the nearest point of the dark space that is straight away from the negative pole.

We have then two closely adjoining, almost overlapping parts, in which the discharge is in opposite directions, and this could not be unless electricity is carried by matter which can, owing to its inertia and high velocity, move against the electric forces. To my mind this experiment proves conclusively that the negative electricity is bound to matter projected with high velocity away from the negative pole.

Goldstein has shown that when a thin pencil of the negative glow belonging to one electrode passes close to another the pencil is deflected. According to our view, such a pencil would be formed by a succession of negatively charged particles projected in nearly the same direction away from the negative electrode; as these particles pass by another cathode they are naturally deflected out of their path by the electric forces. Goldstein has shown that if the current is equally divided between the two cathodes, the deflection is independent of the intensity of the current, the pressure, and the nature of the gas. This is exactly what ought to happen according to our theory, for strengthening the current at one cathode means, as will presently appear, increasing the velocity of the particles. The square of the velocity will increase in the same ratio as the total fall of potential in the neighbourhood of the negative pole; as the particles pass the other cathode, the forces from it are increased in the same ratio as the square of the velocity with which they are moving, and consequently the path will remain the same. Similarly all the other experimental facts established by Goldstein can be easily explained.

The most conclusive proof of the view adopted in this paper would be found in the demonstration that the amount of electricity carried by each particle was always the same, whatever the current. I propose to test this fact in the following way: It was found by Hittorf that the particles proceeding from the negative electrode, and projected at right angles to the lines of force in a magnetic field are bent round in a circle. This is as it should be, and I calculate that the radius of the circle ought to vary as $\sqrt{F/e}$, where F is the total fall of potential within the region in which the particles acquire their velocity, and e is the amount of electricity carried by each particle. As the current increases, it is shown by Hittorf that F increases; and I find that at the same time the diameter of the ring in the magnetic field increases. If this diameter varies as the square root of F, it would be proved that e must be constant as it is in electrolysis. At present we can only say that the average amount of electricity carried by the particles must increase less rapidly than the fall of potential. If e varies at all, we should expect it to vary proportionally to the fall of potential in the neighbourhood of the negative electrode, and in that case the diameter of the ring would be independent of the current, which it is not.

The theory which I advocate involves the existence of a polarisation, and it might be considered a difficulty that no polarisation currents have with certainty been observed in gases. I believe the difficulty only to be apparent, for the experiments prove that the fall of potential near the negative pole, though rapid, is not sudden, so that the layer within which the condenser action takes place is very much thicker in gases than in liquids. The capacity of the condenser is therefore smaller, and though the total fall of potential in the gas may even be stronger than in the liquid, the polarisation currents might escape observation.

With regard to the positive part of the discharge, it will be sufficient here to mention that stratifications are principally observed in mixtures of gases or in compound gases, and that in the intervals between two stratifications the discharge is very likely carried as through the dark space at the negative electrode, while in the stratifications recombination of the decomposed atoms takes place.

An interesting law has been proved by Hittorf and E. Wiedemann in the case of the unstratified discharge. Hittorf shows that the fall of potential is the same in the positive part for the same tube whatever the current. This means that the energy dissipated is proportional to the current, and not to the square of the current as in a liquid. In the latter form the proposition had previously been proved by E. Wiedemann, who has shown that the total quantity of heat generated is proportional to the total quantity of electricity which has passed through the tube, whether in a few strong sparks or many weaker ones.

These experiments seem to point to the fact that once the original velocity of the particles at the regular pole has been reduced the velocity becomes independent of the strength of the current, that is to say, that in the positive part of the current greater intensity only means a greater number of particles taking place in the discharge.

The paper also contains spectroscopic evidence as to the state of dissociation in a vacuum tube, especially in the negative glow.

The question as to how the electricity passes from the electrode to the gas is not discussed, nor is it possible at present to decide, should the theory prove true, whether the polarity of the atoms in the molecule depends on the way in which these are combined, or whether that atom takes positive polarity which happens to be nearest the negative electrode as the molecule approaches it.

In conclusion some novel influence of the magnet on the negative glow is described, and it is shown that two different effects have to be clearly distinguished. The first is an effect of the magnet on the discharge when that discharge is established, and has been sufficiently well investigated. But the second effect depends on the question from what part of the negative electrode the discharge sets out. With respect to this question we meet with many contradictory and inaccurate statements. If at any place the magnet tends to throw the glow together the temperature will be raised, and owing to this fact the current will be strengthened, which again raises the temperature. It may thus happen that a slight cause can induce the current to pass almost exclusively from one part of the negative electrode. For a detailed description the reader is referred to the paper itself and the illustrations accompanying it.

LEGAL.

Central News v. Eastern Telegraph Company.

This case came on on Saturday morning last, before the Lord Chief Justice, for further consideration on the findings of the jury which took place at the last sittings before his lordship and a special jury in the Queen's Bench Division. The defendants are the Eastern Telegraph Company, Limited, and the Exchange Telegraph Company, and coupled with these defendants were Sir James Anderson, the managing director of the Eastern Telegraph Company, and also at the time in question a director of the Exchange Telegraph Company, and Mr. Benjamin Smith, the chief officer of the former company at Alexandria. The action was brought against these companies and their representatives above named, individually, to recover £10,000, in consequence, as alleged, of the Eastern Telegraph Company having divulged to the Exchange Telegraph Company the contents of a message entrusted to their care at Kassassin by Mr. Burleigh, the special correspondent of the Central News in Egypt during the late war, announcing the fall of Tel-el-Kebir, whereby the Exchange Company were enabled to publish the first intelligence of the issue of that battle, to the detriment of the plaintiffs, in this country. The substantial defence, as our readers already know—*vide Electrician* for May 10th last—was that the news in question was not purloined from the Burleigh telegram, but was gathered from a telegram transmitted by Sir Charles Wilson from Kassassin to Sir Edward Malet at Alexandria, to whom Mr. Benjamin Smith, who was then on board the Eastern Telegraph Company's ship, "John Pender," at once sent it off, and having copied it, sent it as a "service message" by the company's wire *viâ* Malta and Marseilles, and thence to Sir James Anderson, the managing director of his company in London, who, or those who represented him, in turn transmitted it to the Exchange Telegraph Company, which had no correspondent at the front. The Burleigh message was to this effect. "Kebir taken by assault, enemy in full retreat; over 2,000 slain; our loss about 200 killed; forty guns taken; cavalry now in pursuit." This important news was absolutely gathered by Mr. Burleigh on the battlefield, and it was proved that no other correspondent had in his telegram made any allusion either to the guns captured or the number of killed, although these figures were introduced in the telegram sent by Sir Charles Wilson to Sir Edward Malet, and who, it was alleged, had obtained the intelligence from Mr. Burleigh's

Digitized by Google

message during the military censorship of all messages from the seat of war at Kassassin. The trial extended over several days, and in the result the jury, answered the questions put to them by Lord Coleridge, firstly that Sir C. Wilson did indirectly make use of the Burleigh message, and secondly that the Eastern Telegraph Company had not divulged the Burleigh message to the Exchange Telegraph Company to the detriment of the plaintiffs. On these findings his lordship reserved judgment, and the case now came on for argument.

Mr. Murphy, Q.C., Mr. H. Dickens, and Mr. A. M. Sullivan were counsel for the Central News (the plaintiffs in the action); the Attorney-General, Mr. Charles Russell, Q.C., and Mr. Moulton were counsel for the Eastern Telegraph Company, Sir James Anderson, and Mr. Benjamin Smith. The Exchange Company was represented by the Solicitor-General, Mr. Bompas, Q.C., and Mr. Jeune.

On the case being called on,

The LORD CHIEF JUSTICE, addressing Mr. Murphy, Q.C., for the plaintiffs, said: I did not give judgment because on the finding of the jury they would not assess any damages, for they found there was no divulgence of the telegram to the detriment of the plaintiffs. I was very anxious that the jury should assess the damages, if any.

Mr. MURPHY: I asked your lordship to direct the jury whether there was any interference with the rights of the plaintiffs in the telegram of which Mr. Burleigh had the property.

The LORD CHIEF JUSTICE: It seems to me that the finding of the jury put you out of court, and I think the best thing I can do is to give judgment for the defendants, and leave you to move.

Mr. MURPHY: If so, may I ask your lordship what was the good of reserving this case for further consideration?

The LORD CHIEF JUSTICE: I am not sure, if you ask me to be candid, that there was any good at all in it. I certainly directed the jury that if there was a message from Sir Charles Wilson to Sir Edward Malet, some of which was taken from the Burleigh message, that of this the plaintiffs had a right to complain. If I was wrong this was misdirection, and you are entitled to a new trial. I will now give judgment on the findings of the jury for the defendants, and on this Mr. Murphy may move for a new trial.

The ATTORNEY-GENERAL: Does Mr. Murphy contend that on the finding of the jury judgment can be entered for the plaintiffs?

Mr. MURPHY: I think not on the findings.

Mr. RUSSELL suggested that on one paragraph, No. 7 in the statement of claim, judgment should be given for the plaintiffs, with nominal damages, this being as regarded the plaintiffs' common law right in the telegram.

Mr. MURPHY: I certainly think I am entitled to judgment on that part of the case. Would it be a convenient course to leave either party to move for judgment?

The ATTORNEY-GENERAL: No.

Mr. RUSSELL: No, no.

Mr. MURPHY: I would rather not have to argue the case before you a second time. I have got a whole battery behind me [laughter].

The LORD CHIEF JUSTICE: I think the most convenient thing is that I should give judgment for the defendants, and then the whole matter can be raised before the Divisional Court.

His LORDSHIP accordingly entered judgment for the defendants.

This decision will be appealed from.

The Lancashire and Cheshire Telephonic Exchange Company (Limited), Appellants, v. the Overseers of Manchester, Respondents.

This case came before Mr. Justice Mathew and Mr. Justice Day in the Queen's Bench Division of the High Court of Justice on the 3rd inst. It was a special case stated for the opinion of the Court upon the question whether a telephone company were liable to be assessed for rates in respect of their telephone posts and wires standing upon ground or attached to buildings of which the company were not occupiers or owners. The Telephone Company carry on business in Manchester, having a central office in the centre of the Exchange system, with wires running thence to the premises of their subscribers. These wires, which are overhead, were erected by the company, but are used exclusively by the subscribers, the wires being attached to buildings or to posts placed on buildings by the consent of the owners or occupiers, and the company's servants can only get at them by entering the buildings upon receiving permission from the owners or occupiers. The wires, posts, &c., of the company had been assessed at £2,000 rateable value, and against this assessment the company appealed, contending that their occupation was not such as to make them liable to rates, being neither exclusive nor permanent.

Mr. Webster, Q.C., and Mr. Henn Collins, Q.C., appeared for the company; Mr. Ambrose, Q.C., and Mr. Smyley for the overseers.

Mr. Justice MATHEW, in giving judgment against the contention of the company, said that the case was concluded by the decision in the case of The Electric Telegraph Company v. The Salford Overseers (reported in 11 "Exchequer Reports," p. 181, in which it was decided that the Electric Telegraph Company were liable to be rated in respect of their wires and posts placed along the lines of railway companies, although the latter could have required their removal to a more convenient place). There the question raised was whether such property was capable of rateable occupation, and the Court held that it was. The case here was the same, the posts and wires were in the exclusive and permanent occupation of the company. There was therefore nothing to distinguish this from the earlier case.

Mr. Justice DAY concurred.

Re Devon and Cornwall Electric Light Company.

On Friday, the 3rd inst., before Mr. Justice Chitty, Mr. Ince, Q.C., moved, on behalf of a Mr. Cadogan, that he be allowed his costs in the suit, and his name struck off the list of contributories on the ground of misrepresentation on the part of the company, who alleged that they had certain special privileges, which was proved not to be the fact. A petition was also presented for the winding up of the company, which was opposed; but when the Court decided that there was misrepresentation the petition was allowed to go after being appealed. It was contended on behalf of the company that the applicant had no right to costs under any circumstances.

Mr. Romer, Q.C., was for the company.

His Lordship refused the application, with costs.

COMPANIES' MEETINGS.

Eastern Telegraph Company (Limited).

The twenty-fourth half-yearly general meeting of this Company was held on Thursday, under the presidency of John Pender, Esq., M.P.

The CHAIRMAN reviewed the financial results of the half year's work as detailed in the report of the directors, and stated that the repairing expenses had been £37,113, being a decrease of £13,788 as compared with the corresponding period of last year. They carried to the general reserve fund £65,000, making that sum, with interest on investments, £614,170, from which amount they had applied £300,000 in part payment for new cables, leaving the general reserve at £314,170. But the total amount of the reserve fund, including the Sardinian cable and other special reserves, was now £349,777. The investments against this were £328,574. In addition to that £100,000 had previously been taken from the fund in part payment of expenditure on account of the Aden-Bombay duplicate cables. Since the amalgamation in 1872 the ordinary working expenses had averaged nearly 26 per cent. of the revenue, and the repairs had averaged 11 per cent. The average amount carried to reserve had been £50,000 per annum. The number of stations in 1881 (to give a review of the last three years) was 42, and in 1884 there were 50. The number of the staff in 1881 was 419, and in 1884, 533. Since March, 1881, they had laid the Malta-Tripoli, the Trieste-Corfu, and the Alexandra-Port Said cables, besides the Suez-Aden triplicate cable and the cable connecting Suakim, being a total length of 2,440 miles. The present length of the cables (including the Black Sea) was about 19,000 miles, and the land lines about 3,000 miles. With regard to the issue of £500,000 of debenture stock at 5 per cent., many thought it a bold thing to offer stock at such a rate of interest, but it had been all taken up, and more would have been taken had they had it to allot. Having given the full details of the manner in which the money so obtained had been dealt with, he alluded to the satisfactory results of the opening of the station at Glasgow. As to the triplicate cable which they had laid in the Red Sea, he thought that step might be regarded as showing a display of foresight, because but for it they could not have given the country the enormous advantage of telegraph communication later on with Suakim. He regarded this as a very important feature in the history of the Company, and they had no reason to regret having carried out this work, as it had already given them a fair return. At their last meeting he had told them that they had made arrangements with the Greek Government for the completion of their system, and that work was all but completed, and when finished they would have connected twenty five islands in Greece with the Government of that country. One of the results of their visit to Constantinople in the autumn had been a concession from the Turkish Government, which gave them in the Mediterranean and the Levant a very strong position indeed. When referring to the Suakim cable he ought to have mentioned that the Government contemplated making a railway from Suakim to Berber. If that were done he had no doubt that Suakim would be a very important point in the Red Sea. He then referred to the preponderating interest which they had acquired in the Direct Spanish Company, and afterwards announced the receipt of a telegram a few minutes previously stating that the necessary authority had been obtained from the Italian Government for completing the purchase of the lines of the Mediterranean Extension Company. During the last three years they had done an amount of work which was simply startling. The average of paying words had been 10,300,000 per annum, the number of non-paying being 3,700,000, or a total of 14,000,000 words per annum, being a daily average, including Sundays, of 38,300. He mentioned this that they might understand how much they were in the hands of the young men who were employed to convey these messages, and in the second place because they could well understand during a time of war what the difficulties of maintaining such a system were. He then alluded to the suit which had been going on between the Company and the Central News, and remarked that he thought in view of what he had just stated the wonder was that the matter had come out as it had done, looking at the fact of the frequent attempts which were made to tamper with their *employés*. He regretted that he could not say the litigation was at an end. He thought the other side had to give them some little credit in face of the difficulties against which the Company had to contend, just as they themselves gave the Central News credit of

Digitized by Google

endeavouring to do their work well. He was happy to inform them that their ships at the present moment were not employed, and in the interests of the Company they were well employed when they were doing nothing. He concluded by moving the adoption of the report and the declaration of the dividend and bonus recommended therein, making, with the previous payments, 6 per cent. for the year on the ordinary shares.

The VICE-CHAIRMAN, the Marquis of Tweeddale, seconded the motion, which was carried unanimously after a brief discussion.

A cordial vote of thanks to the chairman and directors was then proposed and seconded, the management of the Company being warmly eulogised.

The CHAIRMAN briefly acknowledged the vote, and the proceedings terminated.

[A full report will appear in our next issue.]

Faure Electric Accumulator Company (Limited).

An extraordinary general meeting of this Company was held on the 9th inst. at the City Terminus Hotel, Mr. Harcourt Turner presiding, to consider the confirmation of the resolution passed at the meeting on the 19th ult. for winding up the Company voluntarily.

The CHAIRMAN stated that the result of the liquidation would be that instead of the directors the liquidators would carry on the affairs of the Company. They would go thoroughly into the accounts, and would have full power to recover any assets. Should it be found that they had any assets—the French patents, for instance—so that the Company could carry on business, the liquidators would call a meeting of the shareholders, with whom the decision would rest whether the Company should be resuscitated, or the assets sold and the proceeds divided. When he went to his office that morning he found a postcard from Mr. Bogler inviting his presence at the meeting to hear an important statement respecting the Company's affairs. He thought it would be advisable that that statement should be made before he put the resolution.

Mr. A. R. BROWN then intimated that he would propose the adjournment of the meeting for fourteen days, and that meantime the resolution for winding up the Company should not be confirmed. Within the last few days important facts had come to his knowledge which led him to hope and believe that the Company might recover its property. He did not believe it would be to the interest of the shareholders that he should disclose at a public meeting the information which had come to him. He would propose that the contract of 1882, made with the Electrical Power Storage Company, by which they ceded their rights and privileges in the the United Kingdom to that company, should be submitted to the Solicitor-General. Counsel's opinion ought to be obtained on it, and if his suggestion were adopted he would be willing to hand the directors a cheque for 200 guineas, or more if necessary, to obtain the high legal opinion he had suggested.

Mr. HENRY STAPLES fully endorsed this proposal, providing the directors saw nothing against it. He had never hesitated to attribute some "hocus-pocus" to the contract, and he endeavoured at the time to elicit from M. Philippart its real nature; but his mouth had been closed by hearing that they were in the hands of M. Philippart. If they found that the sale of their patents to the Storage Company was *ultra vires*, and that no proper consideration was given for them, the agreement might be cancelled by process of law. If they should become possessed of the English patents as well as the French patents—which he maintained were certainly the property of the Company—they would then have something of value.

In reply to a question, Mr. SNELL (the solicitor) stated that nothing had yet been done as to taking counsel's opinion; but he presumed that that would be the first duty of the liquidators after their appointment.

Sir A. J. OTWAY, M.P., thought Mr. Brown's proposal only reasonable, but he would like to know whether the directors saw anything in it which would be prejudicial to the Company's interests. He had had nothing to do with the Company since 1882, but he had always taken a great interest in it. He was satisfied as to the value of the patents; but his information was that the property of the Company had been very improperly parted with, not however in the contract of the date mentioned, but in a contract passed subsequently. It was to be remembered by the shareholders that there had always been this disadvantageous peculiarity about the Company—that more than one-half of the property was held by one person, the individual who had now gone into bankruptcy, and who had been so much denounced (M. Philippart). He at all times had power to do what he chose, owing to the number of shares held by him, and by disseminating them. The old directors nevertheless warned the shareholders against taking the course that gentleman had proposed; but they acted unanimously against the advice of the directors, who then resigned, handing the Company over in a very flourishing condition. The valuable patents and the £23,000 cash had since disappeared, and a later contract had been made signing away their valuable patents. He had received private information which led him to believe that there was very valuable property in the possession of the largest shareholder of the Company (M. Philippart), which property might, by the right steps being taken, be made available to them if the law sanctioned such a proceeding. If the contract which was made subsequent to the one which was ratified by the shareholders should not hold good, they would re-enter into possession of the patents which were made over to the Electrical Power Storage Co. He did not think that anything could touch the contract of July, 1882, because it was made under legal advice, and valuable consideration was given for it. It was also to be remembered that at that time the Faure patents were very much threatened by those who held the Sellon-Volckmar inventions. The secretary would say whether it was right that that contract was submitted to a general meeting.

The SECRETARY (Mr. Herbert Canning) replied that it was "foreshadowed" to a general meeting, not submitted.

Mr. STAPLES repeated that he distinctly endeavoured to elicit information as to what the contract was, but failed.

A letter was then read by the secretary, which had been received from M. Philippart, dated Paris, the 5th inst. He protested against the proposal to go into liquidation, and urged the shareholders to vindicate their right to the exclusive possession of the Faure patents for the whole of the United Kingdom. The Sellon-Volckmar patents were, he wrote, nothing but a counterfeit of the Faure patents, and therefore they received nothing by the first agreement of 1882 with the Storage Company.

The CHAIRMAN pointed out that the adjournment of the meeting would be adverse to the Company's interest, as if there were any delay there was no doubt that others would try and obtain the winding up of the Company.

The resolution was then confirmed, on the motion of the CHAIRMAN; and subsequently a resolution was passed appointing Messrs. F. Cooper (of Cooper Brothers, chartered accountants), H. Canning, and A. R. Brown as liquidators.

PHILADELPHIA ELECTRIC EXHIBITION.—WANTED by an Electrician proceeding to above, total or partial CHARGE of EXHIBITS. Can give good references. Address, care Mr. Cheyne, 135, Stamford-street, E.C.

THE ADVERTISER seeks a SITUATION as PHYSICAL DEMONSTRATOR. Has had five years' experience at two colleges. Reason for leaving the present position is the rearrangement of classes. Good practical knowledge of electrical testing. Good testimonials. Address, "Ohm's Law," *The Electrician* Office, 1, Salisbury-court, Fleet-street, E.C.

NOTES.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 11th July were £2,539.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.—This company will pay a dividend of 12s. per share. The transfer books will be closed up to the 22nd inst.

ELECTRIC LIGHTING IN PHILADELPHIA.—The Brush Company in Philadelphia now have 700 lights at work, and by October next expect to be running as many as 1,200 lamps.

THEATRE LIGHTING.—It is stated that the Ambigue Theatre in Paris is to be lighted by arc and incandescent lamps. Twenty of the former and three hundred of the latter are to be tried at first.

STORMS IN MORAVIA.—According to telegrams from Vienna, violent thunderstorms occurred in the beginning of this week throughout Moravia, many houses being struck by lightning, and several persons injured.

EXHIBITION AT ROUEN.—An industrial exhibition has been opened at Rouen. The interior is lighted by Breguet arc lamps, Swan lamps, and Jablochkoff lamps. Among the exhibits is a small electric railway.

THE LEGION OF HONOUR.—The following gentlemen have been nominated for the Legion of Honour:—Dr. D'Arsonval, of the College of France, a well-known electrician; and M. Postel-Vinay, an electrical engineer.

INTERRUPTION OF TELEGRAPHIC COMMUNICATION.—In the early part of this week telegraphic communication between London and Berlin was partially interrupted, owing to the highly charged state of the atmosphere.

LLOYD'S SIGNAL STATIONS.—A Post Office notice says that the Committee of Lloyd's do not allow their signalmen to signal telegraph messages to passing ships unless the sender has made a previous arrangement with them.

TEMPERATURE OF THE SUN.—Professor de Volson Wood, in an article contributed to *Van Nostrand's Magazine* for this month, concludes that, adopting the method of Pouillet, the temperature of the solar surface is less than 6,000deg. Fahrenheit.

REMOVALS.—The Jarman Electrical Company have removed from Richmond-street, City-road, to Mackintosh-lane, Homerton, E.—The registered office of the British Insulite Company has been removed from 20, Coleman-street, E.C., to Charlton, Kent.

CASTLE STRUCK BY LIGHTNING.—Kranichberg Castle, the summer residence of the Cardinal Prince Archbishop of Vienna, was struck by lightning on Sunday. The apartments usually occupied by his Eminence and the old keep of the castle sustained much damage.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th July are £3,120, as compared with £2,389 in the corresponding period of 1883. The March receipts, estimated at £6,255, realised £6,315.

TENDERS FOR LIGHTING.—The Clevedon (Somerset) Local Board are inviting tenders for lighting the streets of that town for nine months from 15th August next. The number of gas lamps now used is 186. Tenders are to be sent to Mr. H. C. Fry, Clerk to the Board, by the 29th inst.

RESIGNATION.—We are informed that Mr. H. Z. Harold has resigned his post in the firm of Messrs. Johnson and Phillips, telegraph engineers, of Charlton, S.E., and Union-court, Old Broad-street, E.C., with whom for some years he has held a responsible position, and is now about to start in business for himself.

THE MAXIM LAMP IN AMERICA.—The United States Electric Illuminating Company have fitted up the following installations in New York:—New York Press Club, 70 lights; Union Club, 130; Lotos Club, 70; Phœnix Insurance Company, 50; and they also have 227 arc lamps running in various quarters of the city.

INCANDESCENT LAMPS.—Mr. H. B. Gale has made a series of interesting experiments on the efficiency of incandescent lamps, the results of which he has contributed to *Van Nostrand's Magazine.* These experiments were carried out in the Massachusetts Institute of Technology. We shall hope to reprint this paper in an early issue.

A NEW TORPEDO BOAT.—An American paper says:—A new torpedo boat which has recently been exhibited to Government officials at Milford Bay is to be taken to the experimental station at Sandy Hook, where it will undergo still further tests. It is driven and steered by electricity, the operator on shore having perfect control of it, although he may be a mile away.

MEMORIAL TO THE LATE MR. SPOTTISWOODE.—It is announced that this memorial has already reached the sum of £662 10s. The committee are desirous of increasing the amount so as to realise their intention of founding the Spottiswoode Memorial Pension in connection with the Printers' Corporation. Mr. Samuel Spalding, of 147, Drury-lane, is the treasurer to the fund.

INDIA RUBBER, GUTTA PERCHA, &c., COMPANY.—According to the report of this company the business of the past half year has been satisfactory, and the directors will, at the ensuing meeting, recommend the distribution of an interim dividend of 5 per cent., or 10s. per share, free of income tax. The half-yearly general meeting will be held at Cannon-street Hotel on the 22nd inst., at 12 noon.

ELECTRIC LIGHTING IN HANOVER.—The printing establishment of Messrs. Jaenecke Brothers at Hanover has been lighted by incandescent lamps for the last six months. The total number of lights employed is 135, of which 125 are 8 candle-power, eight 10 candle-power, and two 16 candle-power, all Edison's make. The machines used are Schuckert's, made by Uppenborn and Gackenholz, of Hanover.

ELECTRIC LIGHT IN MANCHESTER.—The contract for the lighting of Larard's Still, Oldham-street, which is now undergoing extensive alterations, has been placed in the hands of Mr. F. D'A. Goold, electrical engineer and contractor, 29, St. Mary's-gate, Manchester. The lighting will comprise both arc and incandescent lamps, which will be fed by separate machines. The motive power will consist of an Otto 8 horse-power gas engine.

INSTITUTION OF CIVIL ENGINEERS.—The council of this institution have awarded Mr. Thomas Andrews a Telford medal and premium for his paper on "Galvanic Action between Wrought Iron, Cast Metals, and Various Steels during long Exposure in Sea Water." They have also awarded the Miller Scholarship of £40 per annum for three

Digitized by Google

years to Mr. Alfred R. Sennett for his paper on "The Electric Light."

Ship Lighting.—The steamship "Yarra," belonging to the Messageries Maritimes, is lighted by means of 188 Swan lamps, 166 being 10 candle-power and twenty 20 candle-power lamps. Two compound wound Siemens dynamos supply the necessary current. There is also telephonic communication between the bridge and the captain's cabin at the stern. Ader telephones are used, and the captain reports that they have worked extremely well.

Meteorological Forecasts by Telegraph.—The Postmaster-General announces that telegrams containing forecasts of the weather are sent by the Meteorological Office during the harvest, and that such telegrams may, if the addressees make a request to that effect, be exhibited at the local post office instead of being delivered. If one copy is required to be delivered and another to be exhibited an additional charge of 3d. will be made.

A Curious Accident.—A curious accident, says a New York journal, occurred recently on the West Shore Railway, near West Point. The cadets were engaged in target practice with a sea-coast battery, when a shot went 100 yards wide of the mark, striking a steel rail in the centre, bending it in the shape of a letter U, and tearing it from its fastenings. The automatic electric signals used on that section gave warning of the breakage, and the rail was replaced before any further trouble ensued.

Electric Gate Openers for Level Crossings.—A French paper says that the railway companies are about to try an electric gate opener. The method to be tried is briefly as follows:—A catch connected with an electro-magnet keeps the gates closed. An approaching train closes the circuit at a certain distance from the gates, the catch is released and the gates open. When the last carriage has passed the circuit is broken again and the gates close. A bell is also rung as the train approaches.

Fire Caused by Gas.—On Wednesday evening the ventilating shaft above the sunlight in the Royal Albert Hall, South Kensington, was set on fire. Luckily help was close at hand, and the flames were soon extinguished, or history might have had to record the same fate for this building that recently overtook the Brussels Houses of Parliament. Sunlights, as they are called, are prolific causes of fire, and when a few more noble buildings have been burnt down possibly this fact may be recognised and dealt with.

Electric Lighting Provisional Orders.—In the House of Commons, on Thursday, the 10th inst., in answer to Mr. W. Fowler, Mr. Chamberlain said: One hundred and twenty applications for provisional orders have been made to the Board of Trade since the passing of the Electric Lighting Act. Of these seventy-three have been granted by the Board of Trade and confirmed by Parliament. There have been ten applications for licences. One for Colchester will be granted in the course of a few days. The remainder have not been proceeded with by the applicants. The supply of electricity has not been commenced under any of the orders.

Society of Chemical Industry.—On Wednesday, the 9th inst., the annual meeting of this society was opened at Newcastle-on-Tyne. The president, Mr. W. Weldon, occupied the chair, and amongst those present were Dr. Perkin, and Professors Roscoe, Huntington, and Armstrong. The report of the council announced that the members now numbered 1,809, against the 297 who formed the nucleus of the society when started in 1881. The president then delivered his address, which related chiefly to the soda industry and the recent chemical improvements connected with it. Subsequently the members paid visits to the chief works in the neighbourhood.

Underground Wires.—At the last meeting of the New York Electrical Society, Mr. Sinclair, of the United States Experimental Station (for gunnery) at Sandy Hook, gave a short description of the Howe system of underground wires in use by them. He said it was simply a covering of composition of tar, rosin, &c., surrounded with braided cotton, and then painted. Wires thus prepared were then laid in a trench 4ft. deep on a board, and fastened with a wooden cleat about 1in. apart. They were covered with another board, and the trench was refilled with sand. These wires, he said, have worked satisfactorily through the winter, with the ground in some places covered with water and ice.

Eastern Telegraph Company.—Some interesting information concerning this company will be found in our detailed report of the half-yearly meeting of the shareholders. Thus it appears that the number of stations increased from 42 in 1881 to 50 in 1884, and that the staff, in like manner, had increased from 419 in the former year to 533 at the present time. The company have laid the following cables since March, 1881, viz.:—Malta to Tripoli, 204 miles; Trieste-Corfu, 303 miles; Alexandria-Port Said, 153 miles; Suez-Aden, 1,402 miles; connection with Suakim, 178 miles, making a grand total of 2,440 miles. The company now owns 19,000 miles of cable and 3,000 miles of land lines.

Indian and Oriental Electrical Storage Company.—The following is the minute giving particulars of the affairs of this company required by the High Court of Justice before allowing a reduction of capital:—"The capital of the Indian and Oriental Electrical Storage and Works Company (Limited) is £280,000, divided into 10,000 deferred shares of £3 10s. each, and 70,000 ordinary shares of £3 10s. each. At the time of the registration of this minute (July 11) none of the deferred shares have been issued; the sum of £2 5s. has been called up upon each of 30,000 of the said ordinary shares, and the sum of £3 10s. is to be deemed to be paid up upon each of the other 5,000 ordinary shares; and none of the remaining 35,000 ordinary shares have been issued." The original capital of the company was £400,000; according to the above minute it will now be £280,000.

Dry Batteries.—MM. Becquerel and Onimus have been experimenting on dry batteries. Many have endeavoured to obtain a dry cell by mixing sand with chlorhydrate of ammonia. The two above mentioned obtain a modification of this process by mixing plaster with the exciting liquid, and then allowing it to solidify. As this plan can only be adopted with those cells which work only when the circuit is closed, the chlorhydrate of ammonia and chloride of zinc cells are the only ones that can be used to any advantage. Instead of using plaster only, MM. Becquerel and Onimus sometimes mix peroxyde of manganese or sesquioxyde of iron with it. In these cases the E.M.F. is slightly greater. When the battery has run down, all that is required is to moisten with more exciting liquid. The common defect of all dry batteries is that the quantity of exciting liquid being a minimum, the total electrical energy they are capable of furnishing before being recharged is also a minimum

DEATH OF M. L'ABBE MOIGNO.—This celebrated man, both theologian and scientist, died at Paris on Sunday last. His loss will be severely felt, not only in French circles, but outside his own country. He was a marvellously fertile writer, and wrote a great deal for the press and periodical literature. He established a scientific periodical of his own, which he named the *Cosmos*. To this he added the sub-title of *Les Mondes*, by which it is better known at the present day. The Abbé was the descendant of an old Breton family, and was born at Guemenee in 1803. He was taught mathematics at the Jesuits' College in Paris, but one of his treatises being disapproved of by his superiors, he resigned his post, and took to writing scientific articles for newspapers. He was assistant-chaplain at a Paris Lycée, and in 1873 was appointed a canon of St. Denis. He spoke a dozen languages, had a wonderful memory, and in his younger days was acquainted with Humboldt, Arago, and other eminent men of science.

ELECTRIC LIGHTS FOR LIGHTHOUSES.—General Duane has, since August last, been carrying out a series of experiments as to the applicability of electric lights for lighthouse work for the United States Lighthouse Board. The experiments have been carried out at Tompkinsville, Staten Island, the electrical portion being under the charge of Lieut. John Millis. The present result of the experiments is that the electric light is found to be ten times more powerful than the oil light, and that for a given amount of light it is the cheaper of the two. It is said that of the apparatus tried the most useful has been found to be that at present in use in the French lighthouses. Among the dynamos tried have been the Gramme, Elphinstone-Vincent, Siemens, and Weston. The report on these experiments is not expected to be ready for some months yet, but when it does appear it will be of the greatest interest. If the report of the committee now engaged in the same kind of experiments for the Trinity House at the South Foreland should appear contemporaneously with that of General Duane, some interesting comparisons might be made.

DOMESTIC LIGHTING.—Our contemporary, *L'Electricien*, in its last issue, gives some particulars of the lighting of M. Gaston Menier's house. The installation comprises 150 forty-volt Swan lamps, requiring ·7 ampere of current, which are fed by 22 Faure-Sellon-Volckmar accumulators of the 60 kilogram type, mounted in series. These accumulators will give normally from 40 to 45 amperes, or sufficient current for 60 lamps at once. They are charged every day by a Gramme continuous current self-excited machine. This is driven by an Otto gas engine of five horse-power. With a little practice the servant who has charge of the lighting estimates with sufficient accuracy the night's consumption in ampere hours, and recharges the accumulators with just the amount expended, allowing them about 10 to 15 per cent. extra to make up for losses or errors. Suppose, for instance, that during the night 60 lamps have been alight for 4 hours. The total consumption in ampere-hours will have been:—$60 \times \cdot 7 \times 4 = 168$ ampere-hours. He will charge the accumulators on the following day for about 5 hours with a current of 40 amperes, or, in other words, $40 \times 5 = 200$ ampere hours. The accumulators which have been in use for six months or more have only required partial renewing. Our contemporary thinks that this method of running lamps from accumulators is preferable and more economical than that of feeding them direct from the machine, even though the first cost of the accumulators is by no means a small item.

THE NEW STANDARD OF LIGHT.—The practical difficulties in the application of the new standard of light fixed upon by the Paris Congress are likely to prevent its extended use. Dr. Werner Siemens suggests the following modification of this standard, viz., that instead of measuring with the aid of a surface of liquid platinum on the point of solidification, we should measure with solid platinum on the point of liquefication. If the solidifying and melting point of platinum are identical, his method would give absolutely the same results as that of the Paris Congress. If, however, further researches should prove that platinum melts at another temperature than that at which it solidifies, then a correction will have to be made by introducing a coefficient, expressing the proportion between the light emitted by platinum at these two temperatures. The apparatus of Dr. Werner Siemens consists of a closed metallic box, within which a thin strip of platinum foil 6 mm. wide and 0·02 mm. thick can be heated by a current from some cells. A circular opening in one of the sides of the box of exactly 0·1 square centimetre area allows the rays of light from the incandescent platinum (which is immediately behind the opening) to pass out to the photometer. In taking a measurement the current is gradually increased, and the screen of the photometer gradually shifted so as to maintain always a photometric balance between the platinum and the source of light which is to be measured. The position of the screen at the moment when the platinum lamp is extinguished—that is, at the moment when the foil has melted—gives the value of the light measured in new standard units. The platinum foil is coiled upon a small drum, and by means of a set of levers moved by a handle from the outside of the box, a new surface of the foil can immediately be brought before the opening in readiness for another measurement.

PROTECTION FROM LIGHTNING FOR OIL TANKS.—The fires that have occurred in the oil regions of America through oil tanks being struck by lightning, have raised some discussion as to the best protection for these tanks. Mr. Oberlin Smith writes to the Chicago *Industrial World* on the subject, and offers a suggestion. Accepting the theory that the vaporisation of the oil creates a lofty column that acts as a kind of lightning rod, he contends that the way to meet the difficulty is to run a rod or metallic conductor high enough to overtop the inflammable column of vapour, with branches extending laterally to protect against lower clouds that might discharge their lightning in a partially lateral direction. It is said that the lightning at Point Breeze, Philadelphia, where twenty large tanks were recently destroyed, caused an explosion in the air at a height estimated to have been from 100ft. to 300ft. Mr. Smith says: "I do not know whether any experiments have been made with regard to the height and inflammability of these vapour columns; undoubtedly there is a height where the gas is so diluted by air as not to be combustible. Guessing at the subject, it would seem as if a rod extending 300 or 400 feet high might protect a considerable area of oil-yard. A friend at my elbow suggests a construction something like the electric light towers used by some of the lighting companies. The expense of this would not be worth consideration compared with the loss sometimes occasioned by one stroke of lightning, and such a tower might be utilised for lighting the oil works by arc lights in the usual manner. At the top of the tower, a rod cheaply made of gradually reducing gas pipes could be extended a good many feet above the summit, to still further lessen the danger. Of course such a tower should have ample metallic connections with an extensive system of underground water pipes, and all joints should be made with as perfect contact as possible."

WILKINS'S TELEGRAPH.—In turning over the pages of Vol. II. of the *Journal* of the Society of Arts for 1853-4, we came

Digitized by Google

across the following description of the recording telegraph designed by Mr. J. J. Wilkins, which is additionally interesting as containing a reference to Davey's telegraph, described by Mr. Fahie in our eleventh volume. The description is as follows, *vide* p. 135 of above journal:—"A point or marker is held by a spring in contact with a ribbon of paper against a marking surface, and if the marker were moved by the hand, lines of any form might be traced. The marker is mounted upon an iron armature between four poles of two electro-magnets placed *vis-à-vis*. The armature is fixed on a centre between the poles, and attracted each end in an opposite direction. The armature being at rest, equidistant between the magnets, it follows that while the ribbon of paper is travelling between the marker and the marking surface, a line is drawn in the middle of the paper, and any diversion of the armature from the position of rest entails a corresponding diversion of the line drawn, and by the number and form of such diversions the message is composed. The automaton repeater connected with this telegraph is an apparatus devised to carry out the objects of Davey (who, to a certain extent, succeeded to work (*sic*) a telegraph recording instrument), and to act as a relay of power to work other circuits. This instrument, as now constructed, enables the longest circuits to be telegraphed over at once without the operation of repeating. The telegraph is one-wired, and one operator only is necessary. This advantage would recommend it were expense only considered, but the addition of greater certainty is secured likewise. The insulator is a means evident to the most ordinary capacity of accomplishing the insulation of overground wires. November even at the present day (January, 1854) is the purgatory of telegraphs."

THUNDERSTORMS.—On Friday, the 11th inst., a house in the Westmuir of Kirriemuir was struck by lightning. The lightning entered by the kitchen chimney, shattering to pieces a clock, passed to another room, the window of which it smashed to atoms, and then escaped through the roof, damaging the ceiling considerably. The wife of the occupant and her children were at the time seated at the kitchen window, but fortunately escaped uninjured.—A heavy storm of thunder swept over Durham and district on Sunday night about eight o'clock. A contemporary says that at the height of the storm a fire-ball fell on to the road, in front of a number of people who were sheltering in Oswald-court, Church-street. It burst into a myriad of jets of fire, and emitted a strong sulphurous smell, the lights being of dazzling brightness. No damage was done to the roadway where it fell. The thirty or forty people who saw it, however, fled in all directions, notwithstanding that the rain was falling in torrents. At the colliery village of Shield Row, in north-west Durham, a boy was struck by the lightning and killed on the spot.—At Birmingham Barracks, on the same day, a chimney was struck.—On Sunday afternoon, during the races which were being held at Barmen, near Elberfeld, a thunderstorm occurred, and the lightning struck a circus while the performance was going on, with the result that four persons were killed and seven severely and many others slightly injured.—During a storm which passed over the North Riding of Yorkshire on Sunday night the vicarage of Osmotherly was struck by lightning, and the gable end carried away and other damage inflicted. A cottage near Sutton was struck and the furniture destroyed. Some farm buildings belonging to Mr. Carver, at Thirlby, were unroofed, and clover and haystacks swept away. The lightning struck the workhouse at Guisborough, entering a room in which there were eighteen females sleeping. The ceiling was damaged, a water pipe in the room broken, and one of the beds scorched, but the inmates were unharmed. At Mickleton-in-Teesdale twelve sheep were killed.

EFFECTS OF LIGHTNING.—Mr. Worthington G. Smith writes to *Nature* as follows:—"On June 6th, 1881, I was in the open country, near the sea, between Gosport and Southampton, in a place where there was no shelter. Here I was suddenly overtaken by a violent storm of thunder, lightning, and rain. Before I had time to think of escape the air became darkened by the pouring rain, and to save myself from a drenching I, perhaps foolishly, put up my umbrella. At the same instant I saw a blaze of fire on the right hand side of my face; the thunder burst at the same moment, and a violent wrenching pain seized the fingers of my right hand (which held the umbrella), the pain instantly travelling to my elbow and shoulder, where it ceased. With the exception of a strong pain in the arm like rheumatism for the rest of the day, I felt no further ill effects. There is a blind beggar sometimes seen about here [our contemporary omits Mr. Smith's address, but we gather from his letter that it is somewhere between Gosport and Southampton], who carries a label stating that his eyes were destroyed by lightning. There is no iris to either eye; both are quite white. One day lately I asked him how he lost his sight. He said that he was leaving a country public house during a thunderstorm, and he received the blow from the lightning at the street door as he stood on the top of a short flight of stone steps. He could only remember seeing the blaze of the lightning and being hurled to the ground down the steps into the street. On his senses returning he was blind. He states that he had a little glimmering sight at the time of recovery, but first one eye and then the other soon became totally blind." Mr. Smith also mentions that on the 5th July, 1881, at 11:30 p.m., he saw a ball of fire drop from the clouds to the earth. The descent was rapid, but not comparable with lightning, and with an inclination to the east. The ball appeared large, and about $\frac{1}{2}$ or $\frac{1}{3}$ the apparent size of the moon. Mr. Smith mentions that this ball of fire was also independently observed by another man at the same time.

ELECTRIC LIGHTING FOR DANCES.—Two dances given by Mrs. Mendl, of 39, Holland Park, on Tuesday and Thursday, were much enhanced by the rooms being lighted by incandescent lamps. Although both evenings were extremely hot, the rooms, as usual when lighted by the electric light, were not nearly so close as when lighted by gas on a cool evening. The following particulars may be of interest:—The size of the dining room was 27ft. by 16ft. by 13ft. high; this being merely a refreshment room was underlighted, except at the extreme end over the table, where there were two 20 and one 10 candle-power lamps. At the other end of the room there was only one 20 candle-power lamp. The drawing room, where the dancing took place, was 34ft. by 19ft. by 13ft. high; this room was brilliantly lighted. There were twelve 10 candle-power lamps in the centre chandelier, three 20 candle-power lamps hanging from pendants in the centre of each window, one on a statue underneath, and one 20 candle-power lamp at the further end lighting up the conservatory as well as one end of the room. One 20 candle-power lamp was arranged under water in the conservatory. The hall was well lighted by one 20 candle-power lamp in front and one 10 candle-power lamp behind, the size being 32ft. by 7ft. by 10ft. high. The supper-room upstairs, 27ft. by 16ft. by 10ft. 6in. high, was very brilliantly lighted with six 20 candle-power lamps hung as pendants, with small globes. The lamps being of the new Woodhouse and Rawson type took very little current. From 9:30 to 12 o'clock—that is, before the supper room was

Digitized by Google

lighted—15 amperes were required; from 12 to 2:30, 21 amperes; from 2:30 to 3:50, 15½ amperes. On the second night the current was slightly in excess of this, there being more cells switched on. Thirty-one horse-power Faure-Sellon-Volckmar cells were used, and the total number of ampere hours taken out of them was 252. The lamps were running somewhat over 20 and 10 candle-power. The lamps, instruments, wires, &c., were supplied by Messrs. Woodhouse and Rawson, and the installation was superintended by Mr. E. Manville.

The Swan and Edison Works at Newcastle.—The Association of Sanitary and Municipal Engineers opened their annual meeting last week at Newcastle-on-Tyne, under the presidency of Mr. W. G. Laws, the borough engineer of that town. Among the works visited during the course of the meeting, which extended over several days, were those of the Edison and Swan United Electric Light Company. We extract the following account of the visit from the *Newcastle Chronicle*:—"This establishment is rigorously closed to the public, and the privilege of inspecting the modes by which the Swan incandescent lamps are made has very rarely been accorded to any number of persons. The industry is an entirely new one, and machinery and tools have had to be invented for carrying out its processes. Many of the work-people employed are Germans, and the rules and instructions for the guidance of the hands are in several cases printed or painted in two languages. The members of the visiting party were conducted over the greater part of the establishment, and were shown the means by which the filaments and platinum wire attachments were prepared and fitted into the now familiar lamps. The next section of the work inspected was that connected with the exhausting of the atmospheric air from the lamps and the securing of a non-conducting vacuum in their interior. A most ingeniously designed machine is used for this purpose, and the visitors spent a large proportion of the time at their disposal in examining its plan and mode of operation. Finally, the party was conducted to the testing rooms, where the lamps were seen lighted on a frame so placed that the rays from each were thrown through a slit on to a screen in a darkened chamber. In this recess a youth separately compared the lights with the illumination given by a standard lamp, and called out the result as 'bright,' 'dull,' or 'standard,' as the case might be. In the manager's office were shown a number of very beautiful coloured lamps, and, much more interesting, the apparatus respectively used for measuring the strength of the currents generated by the supplying machinery, and the intensity of the illumination produced."

Magnetism of Organic Bodies.—Herren Wleügel and Henrichsen have investigated this subject and communicated their results to *Wiedemann's Annalen*. We condense the following from a translation in the *Phil. Mag.* for July:—"The authors have examined the magnetism of some compounds of the alcohol radicals C_nH_{2n+1}. The bodies in question, which were partly prepared by the authors themselves and partly obtained from M. Kahlbaum, were all carefully purified before being used. For the measurements, they were placed in a small glass vessel. This was of a somewhat long horizontal shape, and had a bifilar suspension, so that it oscillated between the pointed half-armatures of a large horseshoe electro-magnet. The current was that of 16 – 18 Bunsen's elements. The magnetism excited in the bodies was measured by a torsion method with a mirror reading like that previously used by G. Wiedemann. The results are collated in the following table; *m* is here the specific magnetism, that of water being – 100, μ is the molecular magnetism, and *q* the molecular weight. The negative prefix indicates diamagnetism. The magnetism of the displaced air was taken into account. The numbers here given are only provisionally to be considered as correct, as the authors wish once more to test the purity of the substances used. They are, however, sufficiently trustworthy to justify several interesting conclusions:—

Accident from Lightning in America.—The Rev. H. C. Hovey writes to the *Scientific American* giving an interesting account of the effects of a lightning stroke at the new drill hall of the State University at Minneapolis on June 12:—"At 2 p.m. there were 1,000 children assembled on the stage of the hall, and about 3,000 persons in the audience. A thunderstorm arose, and while the children's choruses were going on it was noticed that the series of electric lamps, fifteen in number, hanging from the dome, were lighted at each flash of lightning, going out again at once, and a sense of uneasiness pervaded the people. Herr Scaria had just opened the rear door of the stage, a solo from him being next in order, when suddenly there was a loud report, as if of heavy ordnance, balls of fire were distinctly seen through the large skylight, and following the electric wires away from the building. Subsequent examination showed that the lightning first struck the flagstaff surmounting the door, thence pierced an oaken beam to which the staff was fastened, the splinters, or the concussion, breaking the glass in the skylight. An iron rod conducted the current to the network of electric wires below, where the charge was divided, a portion being harmlessly distributed over the general circuit, and the remainder shattering several electric masts near the building. What drew the lightning was the metallic ball surmounting the tall flag-staff, fifty feet from the wires, and not the wires themselves. There is not the slightest doubt, says Mr. Hovey, that these latter performed the duty of lightning rods in this instance, although not put up for that purpose. Mr. Noyes, foreman of the Brush Company, tells an interesting experience. He was at work on the wires previous to the storm, and kept on after it burst, although aware of his danger. At the moment the building was struck he was splicing the wires directly above the central lamp, meanwhile taking every precaution possible under the circumstances. For a few minutes he lay unconscious, and then regaining his senses descended to the ground. He says that he did not feel any pain until he reached *terra firma*, when he suffered intensely in his right foot. On examination he found that the bolt had struck his leg below the knee, tearing the clothing to shreds, bursting open his stout boot from heel to toe, and blistering the flesh as if with a hot iron.'

ELECTRO-CHEMISTRY.—Inorganic.

BY DR. G. GORE, F.R.S.

(CONCLUDED FROM PAGE 199.)

In a third similar experiment, by using a large sheet platinum anode and a small platinum cathode, and a current from ten Smee's cells during two hours, the phenomena were the same as in previous experiments. The anode lost 28 grains; much loose platinum collected on the cathode, which was neither corroded nor alloyed. The saline residue contained a trace of dissolved platinum salt, and nearly all the corroded platinum in a metallic state. In a fourth experiment I continued the action during three and a half hours; the results were as before. The loss of the anode was 35·73 grains. The saline residue contained a small quantity of dissolved double fluoride of platinum and potassium, which, after being well washed, was dried and heated to redness; it then shot about as if gas was evolved from it. In a fifth similar experiment, lasting four and a half hours, at the lowest possible fusion temperature, more of the brown platinum salt formed at the anode and dissolved in the liquid. The anode lost 64·81 grains. In a last experiment I electrolysed a gently fused mixture of 900 grains of the pure double salt and 100 grains of pure argentic fluoride, with a large anode of platinum and a large cathode of silver. Conduction was complete with ten Smee's cells. No gas was evolved at either electrode. The surface of the anode disintegrated rapidly and lost 49·84 grains in four and a half hours' action. The separated platinum dissolved only to a small extent in the liquid, and subsided in admixture with the silver to the bottom of the vessel as a fine, black powder, weighing 73·93 grains, which lost less than two per cent. when heated to redness. Some grey silver powder was deposited upon the cathode. In all these experiments with the acid fluoride, saline films continually formed upon the surface of the liquid. They came from the cathode and were more abundant the deeper the cathode was immersed.

I electrolysed a nearly saturated aqueous solution of pure fluoride of potassium by means of a current from six Grove cells with large platinum electrodes. Conduction was copious, and the liquid acquired a nearly boiling temperature. Much gas, having an odour like that of a mixture of ozone and chlorine, was evolved at the anode. A saturated solution of the same salt, electrolysed by a current from ten large Smee cells with large platinum electrodes, evolved gas at each electrode. That from the anode smelt powerfully of ozone, and reinflamed a red hot splint. Several other experiments with variations in the size of the electrodes were made, and with addition of hydrofluoric acid, but the results were similar.

I saturated some pure dilute hydrofluoric acid of 40 per cent. at 60° F. with pure double fluoride of hydrogen and potassium, and electrolysed the solution by a current from 10 Smee's cells, a gold anode, and a platinum cathode, during 5½ hours. Gas was evolved freely from both electrodes, and a strong odour of ozone was observed. The anode lost 1·73 grain, and the cathode acquired first a gilded appearance and then a black coating, and the liquid became black with finely divided matter.

Electrolysis of Potassic Chloride. — KCl. Molecular weight = 74·6. Matthiessen separated the metal from this salt by means of a current from six Bunsen's elements with carbon electrodes. He melted a dry mixture of one molecular weight of potassic chloride and one of calcic chloride, arranging the distribution of the heat so that a little of the mixture remained unfused around the upper part of the cathode. Chlorine escaped at the anode, and pure potassium accumulated around the anode beneath the crust. The crucible was then cooled, and its contents removed under rock oil (Watts's "Dictionary of Chemistry," Vol. IV., p. 692.)

Electrolysis of Potassic Chlorate.—$KClO_3$. Molecular weight = 122·6. According to Brester, the electrolysis of melted potassic chlorate, with a platinum anode, yielded potassium, which united with a cathode of copper or platinum. Chlorine and oxygen, with an odour of phosphorus, were set free at the anode, and formed thick white vapours by contact with water (*Chem. News*, Vol. XVIII., p. 145).

Electrolysis of Potassic Iodide.—KI. Molecular weight = 166·1. According to H. St. Claire Deville, silver renders a solution of potassic iodide alkaline by simple immersion in it; it also liberates potassium by a similar reaction when immersed in the fused salt (*The Chemist*, New Series, Vol. IV., p. 329). I have noticed that mercury, by prolonged contact with a perfectly neutral solution of the salt, renders it faintly alkaline. Faraday found that by passing an electric current through melted iodide of potassium, iodine was set free at the anode and potassium at the cathode.

Electrolysis of Potassic Carbonate.—K_2CO_3. Molecular weight = 138·2. By the electrolysis of solutions of hydropotassic carbonate, carbonic anhydride is very incompletely evolved at the anode (C. Luckow, *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 283). According to Faire and Roche, in the electrolysis of solutions of alkaline carbonates or bicarbonites, the molecule splits up in such a way that an atom of potassium or sodium is set free at the cathode, and liberates hydrogen (*Chem. News*, Vol. XXX., p. 63; *Jour. Chem. Soc.*, Vol. XII., p. 861).

Electrolysis of Potassic Cyanide.—KCy. Molecular weight = 65·1. According to H. St. Claire Deville, even platinum, in a state of fine powder, when immersed in a boiling hot solution of this salt, liberates hydrogen. By the electrolysis of a solution of potassic cyanide, Kolbe observed that potassic cyanate was formed at the anode (Watts's "Dictionary of Chemistry," Vol. II., p. 190). Faraday noticed that the aqueous solution yielded by electrolysis hydrogen and potash at the cathode, but no oxygen at the anode; that the liquid around the anode became brown, that the fused salt, and that aqueous solutions of potassic sulphocyanide and ferrocyanide behaved similarly (Gmelin's "Handbook of Chemistry," Vol. I., p. 458).

Electrolysis of Potassic Ferrocyanide.—KFCy. Molecular weight = 368. When a solution of ferrocyanide of potassium is decomposed by an electric current, ferricyanide of potassium is formed at the anode, and hydrogen and potash appear at the cathode (Watts's "Dictionary of Chemistry," Vol. II., p. 240). The alkaline ferrocyanides yield alkali at the cathode, and hydrocyanic acid and Prussian blue at the anode, unless the anode is composed of copper, in which case a deposit is there formed of cyanide of copper (Porrett, *ibid*, p. 222).

Electrolysis of Potassic Ferridcyanide.—KFdCy. Molecular weight = 329. Carbon charged with hydrogen easily reduces a solution of ferri to ferro-cyanide of potassium (Gladstone and Tribe, *Jour. Chem. Soc.*, Vol. XXXIII., 1878, p. 309). A platinum hydrogen couple does the same readily (*ibid*). Bottger observed a similar effect with palladium containing occluded hydrogen.

When a solution of potassic ferricyanide is electrolysed by a separate current, yellow prussiate is formed upon the cathode (Watts's "Dictionary of Chemistry," Vol. II., p. 247).

Separation of Rubidium.—Rb. Atomic weight = 85·48. A monad cation. Like sodium and potassium, this metal is separated from its fused carbonate at a white heat by simple contact with carbon. It was first obtained by electrolysing its fused chloride with a graphite anode, and a cathode of iron wire. It has been obtained by electrolysing a fused mixture of the chlorides of rubidium and calcium in their equivalent proportions at a temperature a little below redness. It is also obtained as an amalgam by electrolysing a strong neutral aqueous solution of rubidium chloride with an anode of platinum and a cathode of mercury. The metal itself is decidedly more electro-positive than potassium, and both it and its amalgam decompose water readily (Watts's "Dictionary of Chemistry," Vol. V., p. 129).

Separation of Caesium. — Cs. Atomic weight = 132·66. A monad cation. Unlike rubidium, potassium, and sodium, this metal is not liberated from its fused carbonate by contact

Digitized by Google

with carbon at a white heat. An amalgam of the metal may be easily obtained by electrolysing a solution of caesium chloride with a cathode of mercury (Watts's "Dictionary of Chemistry," Vol. I., p. 1,114). M. Setterberg obtained metallic caesium by electrolysing a dry mixture of four parts of caesium cyanide and one of barium cyanide. This mixture fuses more easily than caesium cyanide alone (*Chem. News*, Vol. XLV., p. 94, and Vol. XLVI., p. 249).

Separation of Ammonium (?), H_4N_1, and Electrolysis of Ammonia.—H_3N. Weyl, in 1864, discovered that sodium swells, liquefies, and dissolves in anhydrous ammonia liquefied by pressure, and on removal of the pressure the sodium returns to the metallic state; also that potassium behaves similarly; that barium forms a deep blue liquid with a metallic lustre; and that silver, mercury, copper, and zinc likewise form unstable compounds with the liquefied gas (Watts's "Dictionary of Chemistry," Vol. V., pp. 328-329). Seeley in 1870 subsequently discovered that metallic rubidium, potassium, sodium, or lithium, by simple immersion in colourless anhydrous ammonia liquefied by pressure, dissolved in the liquid, and produced intensely blue solutions of powerfully reducing properties (*Chem. News*, Vol. XXIII., p. 169, Watts's "Dictionary of Chemistry," Vol. VI., p. 60). I have also verified these results, and have examined the action of the sodium solution upon various compounds (*Proc. Roy. Soc.*, Vol. XXI., 1873, pp. 140-147). In all these blue solutions it is supposed that ammonium is set free and dissolved.

Bleekrode ascertained that anhydrous liquefied ammonia was a conductor and an electrolyte. He passed the current from 80 Bunsen cells through it; gas was evolved, and the liquid became intensely blue. He also passed the current from 3,240 cells of De la Rue's chloride of silver battery through the liquid by means of platinum wire electrodes. The anode became black, much gas was evolved, and the liquid became intensely blue. On stopping the current the colour disappeared. In these experiments ammonium was probably set free and dissolved, and produced the colour.

Damp iron filings exposed to the air or to nitrogen induce the formation of ammonia (Berzelius).

Electrolysis of Aqueous Ammonia.—By simple immersion of magnesium in solutions of ammonium salts, ammonia and nitrogen are set free (S. Kern, *Jour. Chem. Soc.*, 1876, Part II., p. 479). By electrolysis of ammonium salts ammonia is produced at the cathode (C. Luckow, *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 285). According to Hisinger and Berzelius a concentrated aqueous solution of ammonia conducts as imperfectly as pure water, but by addition of a little ammonic sulphate it is rendered easily decomposable. A gold anode becomes covered with amber coloured fulminate of the metal and dissolves, and the cathode is gilded. With a mixture of one volume of strong aqueous ammonia and three of water, oxygen is set free at the anode, and the anode becomes corroded. With a cathode of mercury, the bulky "amalgam of ammonium" is obtained (Gmelin's "Handbook of Chemistry," Vol. I., p. 458).

According to Favre, under the influence of the current, ammonic oxide is decomposed thus:—1st, $3\ (NH_4)_2O = 3\ (NH_4)_2 + O_3$. The three equivalents of ammonium set at liberty decompose the water, like potassium or sodium, thus:—2nd, $3\ (NH_4)_2 + 3\ H_2O = 3\ (NH_4)_2O + 3\ H_2$. The oxygen of equation No. 1, reacting upon the ammonium, gives:—3rd, $O + NH_4 = N + 2\ H_2O$. The first equation represents the electrolysis proper (*Jour. Chem. Soc.*, Vol. IX., p. 985).

The so-called "ammonium amalgam" with mercury was discovered in 1800 simultaneously by Seebeck, in Jena, and by Berzelius and Pontin at Stockholm. It is obtained either by the contact of sodium amalgam with strong solution of certain salts of ammonia, or by the electrolysis of a concentrated solution of sal-ammoniac, or certain other ammoniacal salts (not the nitrate) with a cathode of mercury. In each case the mercury swells to a bulky mass, which on the cessation of electrolysis, spontaneously decomposes into liquid mercury and a mixture of two volumes of ammonia and one of hydrogen. It solidifies below 0°C., and crystallises in cubes. It does not decompose below 29°C. if previously frozen. In the separate current process oxygen is evolved at the anode, if the salt employed is aqueous ammonia, or the carbonate, sulphate, or phosphate, but chlorine if it is sal ammoniac, and but little gas is set free at the cathode (Watts's "Dictionary of Chemistry," Vol. I., p. 188). If the cathode consists of spongy platinum impregnated with mercury, much gas is evolved and no amalgam is formed (Wetherill, *ibid*, Vol. VI., p. 103). A concentrated solution of trimethylamine hydrochloride behaves with sodium amalgam just like one of sal-ammoniac (Pfëil and Lippmann, Watts's "Dictionary of Chemistry," Vol. VI. p. 104). Various investigators consider the ammoniacal amalgam to be merely a spongy mixture of mercury and hydrogen (*see* Seeley, *Chem. News*, 1871, Vol. XXIII., p. 169; also Pfëil and Lippmann, Watts's "Dictionary of Chemistry," Vol. VI., p. 104).

Electrolysis of Nitrate of Ammonia.—NH_4NO_3. Molecular weight = 80. The action of a copper zinc couple on a solution of ammonium nitrate showed that both nitrate and ammonia were produced. In the cold the nitrate, even in a solution of 20 per cent., was completely reduced to ammonia in about 24 hours, without the escape of ammonia, free or combined (Gladstone and Tribe, *Jour. Chem. Soc.*, 1878, Vol. XXXIII., p. 150).

According to Divers, dry nitrate of ammonia condenses gaseous ammonia and becomes liquid. The liquid ammoniated ammonia nitrate is a good conductor and electrolyte—ammoniacal hydrogen appearing at the cathode, and nitrogen and ammonia nitrate at the anode. Anodes of silver, copper, lead, zinc, and magnesium are dissolved as ammoniated nitrates. An anode of mercury becomes coated with an almost insoluble compound. When the anode is acted upon the evolution of nitrogen does not occur (Watts's "Dictionary of Chemistry," Vol. VII., p. 860. *Chem. News*, Vol. XXVII., p. 37. *Proc. Roy. Soc.*, Vol. XXI., p. 109). Faraday electrolysed fused nitrate of ammonium. Hydrogen gas, mixed with a little nitrogen, was evolved at the cathode. The aqueous solution of the salt similarly treated yielded the same mixture at the cathode and oxygen at the anode.

Electrolysis of Ammonium Fluoride.—H_4NF. Molecular weight = 37. I electrolysed this salt in a state of gentle fusion by means of a current from six Grove cells, a platinum wire anode, and a platinum sheet cathode. Conduction was copious and heat was set free. Much gas appeared at the anode, but no odour of ozone.

Electrolysis of Ammonia Chloride.—NH_4CL. Molecular weight = 53·5. Hisinger and Berzelius by electrolysing with silver electrodes a solution of this salt observed that oxygen was evolved at the anode and hydrogen at the cathode, and the anode became coated with argentic chloride.

Electrolysis of Ammonic Carbonate.—According to Seebeck, a moistened cup of this salt filled with mercury yields by electrolysis with the mercury as the cathode the ammoniacal amalgam. E. Drechsel electrolysed a solution of ordinary commercial ammonic carbonate, by passing a continually reversed current through it by means of platinum electrodes during eight hours. On evaporating the resulting liquid a salt was obtained crystallising in fine white needles, and containing 64·69 per cent. of platinum. About 0·1 grain of platinum was dissolved in 10 hours by the ammonium carbonate. By working the commutator more slowly the temperature of the liquid rose, and by simultaneously cooling a crystalline precipitate occurred, containing 38·6 per cent. of platinum, and was also a salt of a platinum base (*Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 300). B. Gerdes also electrolysed a solution of ammonium carbonate by continually reversed currents from 4 to 6 Grove's cells and platinum electrodes. He obtained besides ammonium nitrite and nitrate, urea, a fatty substance, and a soluble salt of platinum (*Jour. Chem. Soc.*, Vol. XLIV., p. 27).

Electrolysis of Sulphate of Ammonium.—Am_2SO_4. Molecular weight = 132. A solution of ammonic sulphate is decomposed by the current, acid and oxygen appearing at the anode, alkali and hydrogen at the cathode (Sir H. Davy).

Digitized by Google

With iron wire electrodes, hydrogen and free ammonia appear at the cathode, and at the anode oxygen is evolved, but not until after some time; persulphate of iron also appears (Hisinger and Berzelius).

(CONCLUDED.)

Erratum.—Equivalent of Boron $\frac{10\cdot9}{3} = 3\cdot63$.

ELECTRICITY AND LIGHT.—IV.

BY JOHN T. SPRAGUE.

(CONTINUED FROM PAGE 136.)

31. *Light is one of the forms of radiant energy transmitted by undulations*, and in its capacity for moving in distinct straight lines or *rays* appears to be different from such a radiant transmission as that of sound. It is owing to this linear transmission that shadows are produced by light; if we take a cone of rays issuing from any luminous point, or a beam of the solar light the rays of which are parallel because of their vast distance from the luminous centre, and we interpose a screen in the path of the rays, a distinct portion is cut clearly off, and we have darkness behind the screen.

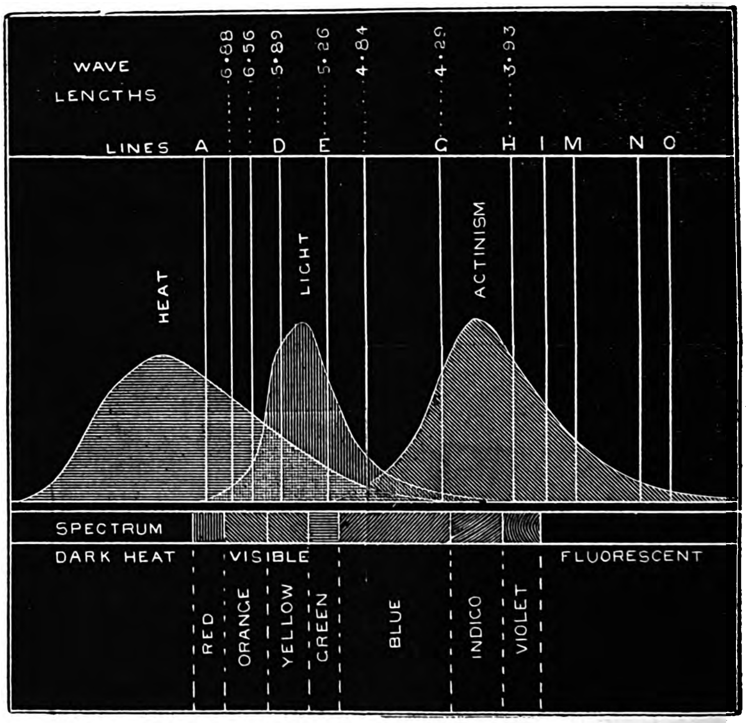
32. *Sound cannot be so cut off*, though its intensity may be diminished. The distinction of the two cases is to be found in the fact that sound turns round corners and light does not; this is at least the apparent distinction. A little thorough examination will prove that it is only apparent, and we can trace out the actual facts through the same illustrations as have already served to explain the various transmissions of energy. If we revert to the conception of Section 17, as developing the linear transmission of energy along a row of billiard balls into a spreading action, we may see that each point of an advancing ray constitutes a fresh radiant point or centre of energy, limited in the direction of its action by that of the surrounding rays, which, constituting the so-called *equipotential* shells, compel the united stream of energy to advance equally in all directions from the centre, and while apparently moving in true radial lines from that centre yet fill all the space they reach and charge every particle of the transmitting agency within that space.

33. The radial lines and the equipotential shells have in fact no true existence. They are produced, not at the apparent centre of action but at each point of the space itself, by the energy transmitted from point to point in the directions of least resistance at each point. The case is identical with the law of transmission of pressure in a liquid, which is equal in all directions, no matter what direction the cause of the pressure acts from. Thus water under pressure turns round any obstacle; *but that obstacle does produce an influence, and is an obstruction.* Thus water flowing through pipes is reduced in quantity by any sharp bends, or by a screen crossing the pipe, although the area available for the stream is not diminished, by a corresponding space being provided beyond the edge of the screen. Now it is evident that behind this screen, where an eddy of water forms, there must be a space in which no stream of water exists; in fact, this screen produces what we may call a *water shadow.* Behind it the lines of pressure of transmitted energy are cut off.

34. *The same effect occurs with sound;* but neither with water nor sound is there complete cut off such as we see with light. The energy presses in all directions and turns round the corners, setting up action behind the screen. But the same thing occurs with light, though not so obviously; it can, however, be traced out by means of the interference of the diffraction lines referred to in Section 29.

35. If we pass a beam of light into a darkened room so as to avoid the effects of diffused light, and interpose an opaque screen to cut off part of the beam and to cast a shadow upon a white screen, we shall find that the line of the shadow edge is not an absolute passing from darkness to equal light. We find it consists of a succession of spaces of greater and less illumination, one set of such fringes extending beyond the true line of the shadow into the light, while another but weaker set occupy a space within the true shadow. The light has thus been subjected to a bending action at the intercepting edge. So evident is this, that if a circular screen is employed, by regulating the dimensions and distances, we may obtain a shadow with a spot of light in its middle, surrounded with a series of dark and lighter circles. These are due to the interferences of the bent rays, which, coming from opposite sides of the circumference, have different distances to travel, and so at spaces corresponding to different wave lengths the two rays reinforce and neutralise each other, while their mutual effect is that of a feeble light thrown upon the true shadow of the screen.

36. *The great rapidity of the motion of light is the cause of the smallness of the quantity of the diffusion.* It is well known that a sheet of thin glass can be perforated by a very sharp and concentrated blow, as by a pistol bullet; in like manner a plank may be perforated by a tallow candle shot at it. With slower motion quite different results occur. On the same principles we can trace effects of deflection of rays of energy through the streams of water, sound, and light as related to the



Spectrum of Radiant Energy.

rapidity of the streams; and in comparing those of sound and light, as related to the wave lengths of the several undulations, which may be roughly averaged as 50in. for sound and 1-50000th of an inch for light.

37. The accompanying diagram represents the analysis of radiant energy as effected by the prism, and as partially manifested in the rainbow. This shows at once that what we call "light" is not a simple entity, but a complex agency, the component parts of which are capable of separation. The first rough separation appears to divide radiant energy into three agencies, or so-called "forces," exhibited by three shaded curves of heat, light, and actinism, or chemical action. The light again appears to be divided into seven parts, distinguished as *colours*, which were at one time supposed to be due to the overlapping of three primary colours; and even yet artists frequently dispute as to whether these three primaries are red, yellow, and blue, as at first supposed, or red, green, and violet.

38. The real truth is that each separate vertical line or section of the spectrum indicates the existence of a distinct agent, each slightly differentiated from its neighbour, and all forming a complete series. The beam of light as it enters and leaves

Digitized by Google

the prism is subjected to a bending action, and the extent of this bending is dependent upon the angle at which the beam crosses the dividing line or surfaces, and the separating power of the prism is dependent on the several wave lengths of the many undulations which compose white light or radiant energy; it simply distributes these distinct undulations in a graduated order of wave lengths.

39. *The spectrum is therefore comparable with the wires of a piano.* Each wire has its own specific rate of undulation, perceived by the ear as a musical note; each line crossing the spectrum has in like manner its own specific rate of undulation and wave-length. *In space, and in the act of transmission, it has no other property,* but it becomes heat, light, or actinism, according to its relations to the object which receives it. Precisely the same occurs with the undulations of sound, which (Section 25) may also be perceived by the sense of touch as a succession of blows. The undulations falling upon the eye produce a sensation which analyses its properties, and light only exists in this sensation and perception. The same ray received upon inert matter sets up certain motions in it, which are *heat;* or the same ray received on some forms of compound matter sets up chemical decompositions. Therefore the three curves shown do not represent distinct forces but the different actions each ray can produce. As a consequence, the curves themselves relate only to particular modes of reception. The normal eye sees the seven graded colours, but it is very doubtful if any two see them exactly alike, and we know that many people are incapable of distinguishing some of the colours. The chemical action also varies greatly with different substances, upon which fact the various photographic processes depend. The actual curve shown is that of the combination of hydrogen and chlorine.

40. The lines shown crossing the spectrum give us the most perfect evidence of these principles. They represent certain dark lines which are found in the solar spectrum, and which are also obtained as distinct bright lines when the light of gaseous flames containing known substances is examined. They are the foundation of spectrum analysis, and as they can be obtained separately they enable their own separate wave length to be measured, as given in 10 millionths of a millimetre in the diagram. This measurement is effected by means of the coloured rings produced when a lens of small curvature is placed upon a flat plate of glass, and still better by the interference lines of light and shade (Section 29), which can be obtained by aid of two mirrors not exactly in the same plane.

41. Solid substances give a complete spectrum corresponding to the conditions, and the conditions depend upon the temperature to which the substance is raised; gaseous substances give only their own specific wave lengths or coloured rays. Thus the line marked D in the yellow is the line of sodium, and is seen when the light of a spirit lamp in which salt is vaporised is passed through a prism. Nothing should be then seen but this bright yellow line, which is really a double one with a dark space in its middle. In the actual experiment there is also a very faint continuous spectrum to be seen, due to the presence of some solid particles in the flame; but this does not affect the conclusions to be drawn from the existence of these constant definite lines accompanying particular substances.

A PHENOMENON IN MAGNETO-ELECTRIC INDUCTION.*

BY C. VERNON BOYS.

This paper dealt with impulses to which conductive bodies are subject when suspended in a magnetic field which suddenly or rapidly varies in strength. A disc of metal hung in a uniform field experiences, when the strength of the field is changed, a twisting force, tending to diminish the angle, and which its plane makes with the lines of force during an increase in the field, and to increase that angle during a diminution of the field. A ring of radius r, sectional area s, specific resistance ρ, at an angle a to lines of force, experiences a couple during a change in the strength of the field $H = -\frac{\pi r^3 S H \sin 2a}{4\rho}\frac{dH}{dt}$. When the field changes from O to H the impulse $= -\frac{\pi r^3 S H^2 \sin 2a}{8\rho}$. If the moment of inertia = M and the value of the torsion of the supporting wire = T, the throw of the ring when the field vanishes will be $= \frac{\pi r^3 S H^2 \sin 2a}{8\rho\sqrt{MT}}$. Corresponding expressions for discs and coils were given. One curious result is that whatever size or thickness (small) a disc of any given material may be, the angular velocity imparted to it during a given change of field intensity is the same.

Discs or coils suspended by torsionless silk threads in a field experience—when that field grows from zero rapidly—throws which depend only on the initial position. The throw is independent of the strength of the field, of the conductivity, or of the moment of inertia of the coil. The time occupied only depends on these things.

In a variable field a disc of metal tends to move to weaker parts during an increase, and to stronger parts during a diminution of field. This effect is so violent in impure copper, which is magnetic, that it appears strongly dia-magnetic.

The results of several experiments were given, which confirmed the formulæ. There was, however, a difference in the strength of a series of fields measured by the new method, and by the deflection of a coil, each in absolute units, which makes further experiments desirable. The method has advantages in point of simplicity and convenience for measuring the electrical resistances of metal in the form of sheets, and for measuring strong magnetic fields.

* Abstract of paper read by him before Physical Society, June 30, 1884.

PATENTS FOR REGULATING ELECTRIC CURRENTS.

BY C. A. STEPHENSON.

It becomes at the very outset necessary for me to wander away from a strict adherence to my subject; but I have to do so in order to lead up to the earlier patents for regulation, which were for automatically regulating the speed of a steam engine driving dynamo machines by means of apparatus actuated by the current produced by the dynamos.

These regulators aim at reducing the speed of the engine as the intensity of the current is increased by the resistance of the circuit being lessened, and are but developments of a still older idea of controlling marine and other engines by electro-magnetic appliances actuated by battery power. It is obvious that very much the same mechanism which was used to set a battery in circuit could be adapted for utilising the current of a dynamo for similar purposes.

In the first patents, therefore, to which I shall call attention, a current of electricity is used for controlling an engine, which itself has no connection with any dynamo or electric current-producing machine.

With these preliminary remarks, I shall now proceed to the question of

Controlling Steam Engines.

The first patent to be noticed was taken out by Mr. Walker Moseley, No. 3802, of 1872. The prime object of this patent is the controlling of marine engines by utilising the motion of the ship for closing the circuit of a battery current. The drawings and details of the specification refer almost exclusively to marine engines, and it would therefore be of little use to reproduce them here. What is material to the present question is that the inventor states that the governor can be actuated by a rotary motion instead of the ship's motion, and could thus be used for controlling land engines; with this view he claims "the use of electro-magnetism for shutting off steam in a land engine when any given abnormal or improper movement of the same takes place." The claim is a very wide one, but as the patent is void it is only as a publication that it has interest. Taking the specification and the claim together they describe the use of electro-magnetism for controlling the speed of an engine by more or less opening or closing the throttle valve.

The next patent bearing in any way on the point is that of Mr. A. M. Clark, No. 2648, of 1874. This patent requires but a cursory notice. It is described as an electro-magnetic governor for steam heating and drying apparatus, "and comprises an engine for working a cut-off valve and a throttle valve of steam-heating apparatus, with automatic apparatus for opening and closing the valves . . . . the apparatus being controlled by electric currents closed and broken by variations of heat through the medium of thermometers in a heated room." This patent is also void.

Digitized by Google

In 1875 Mr. C. C. Walcott took out a preliminary specification, No. 3789, for controlling a marine engine by means of electro-magnetism. In this specification the electric current is used "to control the force exerted for operating the throttle valve of the engine."

In the foregoing patents electricity was utilised as a means of controlling steam engines. The electric currents being produced by batteries were in no way dependent on the engine, but in the patents I am now about to mention a new order of things was introduced.

An electric current is produced by a dynamo driven by a steam engine, and it is attempted to regulate the current by causing it to control the speed of the steam engine through the medium of an electro-magnetic controller. The first patent of this sort was taken out by Mr. St. George Lane-Fox, No. 3988, of 1878. I will describe it in Mr. Fox's own words:—

"In my regulator I make use of what is known as the quadrant electrometer. In this instrument the position of the suspended

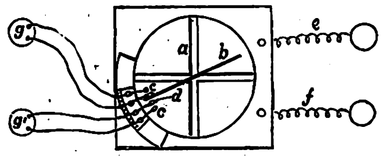


Fig. 1.—Lane-Fox's Electro-Magnetic Regulator.

needle will depend on the relative electromotive force of the so-called quadrants. By connecting this instrument with the main and the earth in the ordinary way, the electromotive force of the main will determine the position of the suspended needle. If it increase or decrease, the position of the needle will be altered accordingly. Now, I fit this electrometer with small pegs, so that a slight deviation of the needle one way or the other will bring it in contact with one of the pegs, and thus complete a circuit, and set up the electric current, which, acting on an electro-magnet, sets a lever or other suitable device in action. The contact with each peg forms a separate circuit, acting independently on two of these levers or other devices, which are in connection with steam valves, one diminishing, the other increasing the supply of steam to the engine which works the electric generators.

"Fig. 1 represents a quadrant electrometer adapted to regulating the electromotive force in the mains as just described; *a a* are the quadrants, *b* the suspended needle, *c c* the pegs of platinum or other suitable material, *d d* are springs situated between the needle *b* and the pegs, *e* is the wire connecting the main, *f* is the wire connecting the earth, $g\ g^1$ are electro-magnets in connection with their respective pegs $c\ c^1$. These magnets act on levers or other devices for operating the steam valves."

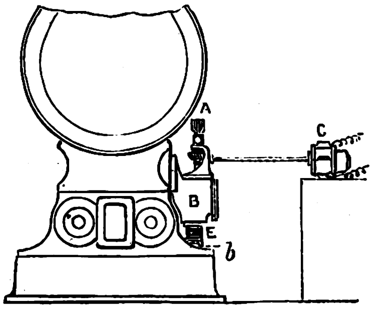

Fig. 2.—Richardson's Electric Governor for Engines.

The foregoing portion of this patent was entirely disclaimed in the second disclaimer to the patent taken out by the Anglo-American Brush Electric Light Corporation on July 30, 1883. The practical effect of this is the same as if all the above was a void patent.

No improvements in this mode of regulation were made for nearly three years, when Mr. John Richardson, of the firm of Messrs. Robey and Co., filed a specification, No. 288, of 1881.

The object of this invention is to regulate to an absolute uniformity the speed of engines employed for driving dynamo machines. To achieve this, in Mr. Richardson's words, "I mount upon the governor itself a small dynamo electric machine, which is actuated by the same current as that which produces the light." A little further on he refers to the dynamo as a motor, and there can be very little doubt that it is his intention to drive the governor of the engine from a motor, the motor being "actuated by a portion of the main current which produces the electric light, and its speed varies in relation to the intensity of the said current, so that when the large dynamo machine which produces the current has reached such a speed as gives the required intensity the governors at the same time attain sufficient speed to shut off all further admission of steam, and the current is therefore retained exactly at this intensity."

Fig. 2 shows an elevation of a Robey engine fitted with the governor.

A is a high speed governor, acting directly upon an equilibrium valve contained within the chest B; C is the motor.

Let it be presumed that the governor acts as described, and that the current in the circuit is kept constant. The infallible law of Ohm's $c = \frac{E}{R}$ will cause the electromotive force to vary inversely with the resistance, so that with every change of resistance in the circuit the electromotive force will vary. Mr. Richardson's conclusion that it is evident that the governing will be perfect will hardly be generally accepted.

In the same year, 1881, Mr. Carus-Wilson took out a patent, No. 5687. The object of this invention is to supplement the action of the governor of an engine so that it shall be made to regulate the cut off with respect to the electromotive force produced.

The revolving governor is acted on by a weight; the weight is controlled by electro-magnets, which are brought into action by currents whose circuits are made or broken by a galvanometer needle.

A reference to Fig. 3 will show clearly how it is proposed to carry this into effect:—*a* is the shaft on which the governor rotates; *b* is part of the rotating gear of the governor, which rises with the increase of speed; *c* is a weight resting on *b* which rises and falls with the governor; *d* is a lever with a fulcrum at *e*, of which the end *f* is forked, and fits into a groove in *c*, so that *c* can turn round and move *d* up and down; $g^1\ g^2$ are two solenoids fixed on a frame *h*, with a common core *j*. *j* is held by a fork, *k*, at the end of *d*; *l* is a spring fixed to *d* and *h*, and capable of being ad-

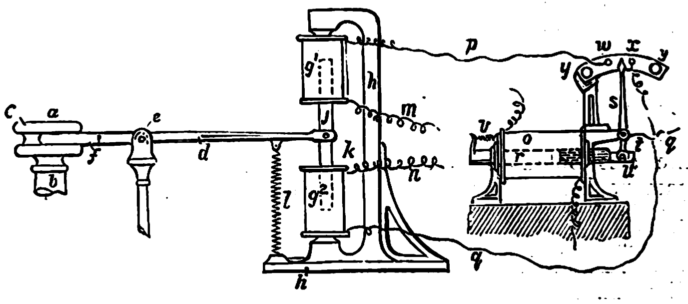

Fig. 3.—Carus-Wilson's Electric Governor for Engines.

justed; the ends *m n* of the solenoids $g^1\ g^2$ are joined together and go to the negative cable of the machine; *o* is another solenoid, with a core, *r*, which extends right through and rides in bearings at each end; the shaded portion is iron; *s* is a pointer pivoted at *t*, and working on a pin, *u*, fixed on *r*; *v* is an adjustable spiral spring; *w x* are two stops of metal, to which are joined the wires *p q*. The wire of the solenoid *o* is in direct circuit between the positive and negative cables; the pointer *s* is of metal and is connected to the positive cable. *v* is adjusted so that at any desired electromotive force the pointer is between the two stops *w x*; *l* is also adjusted so that the weight *c* is raised sufficiently off the governor to allow the engine to attain its proper speed. If for any reason the electromotive force exceeds the proper amount the core *r* is drawn in, *s* touches *x* and makes a circuit between the positive and negative through the solenoid g^2 hence *c* gets lifted, the governor rises, and the speed is diminished.

If, however, the electromotive force falls the converse action takes place, *s* makes a circuit with *w*, and the speed of the engine is increased; *y y* are two screws with milled heads for regulating the position of the stops *w* and *x*.

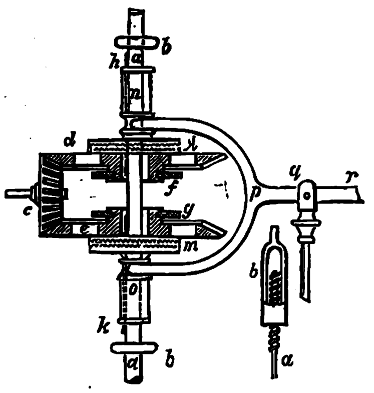
The apparatus is made more or less sensitive by placing the stops *w* and *x* nearer or further from each other; but in any case they should be equidistant from the pointer when in its adjusted position.

The apparatus is somewhat complicated, but Mr. Carus-Wilson explains that it can be simplified by making the core *j* a natural magnet, with a north pole just inside the bobbins g^1, the south pole being just inside the bobbin g^2. The bobbins are wound so that their south poles are opposite each other; *l* is adjusted so as to allow the engine to attain its proper speed; *m* and *n* are joined to the negative, and *p* and *q* to the positive conductor. The whole apparatus lettered *r* to *y* is thus discarded. In this modified arrangement any increase or decrease of electromotive force acts on the governor in the same way as heretofore, but there is a constant current flowing through the coils of the solenoids, the automatic arrangement for making and breaking being entirely discarded.

In the same specification Mr. Carus-Wilson shows "a further development of this principle."

Digitized by Google

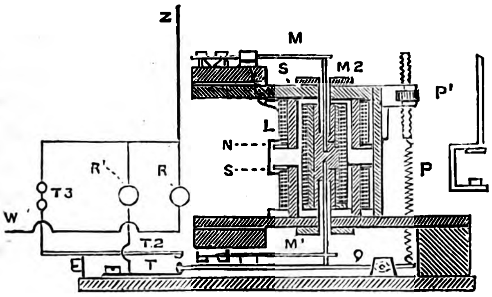
In order to understand the further development a reference must be made to Figs. 4 and 5. In Fig. 4 *a* is one of the rods connecting the governor with the valve gear; *a* moves in bearings at *b b* up and down with the governor, *c d e* are three toothed wheels, *d* and *e*, being driven by *c*; all work in fixed bearings; *d* and *e* move in bearings *f g*. The centres of *f g* are large enough to let pass the rod *a* with keys at *h* and *k*. *d* and *e* carry small collars, *l* and *m*, respectively, each having a row of teeth. Two pieces, *n* and *o*, ride on *a*, and have slots inside to take the keys *h* and k, so that *a* moves freely up and down, but is turned round if *n* or *o* turn round. *p* is a fork at the end of a lever, *r*, pivoted at *q*, and sustains *n* and *o*, so that the rows of teeth on *n* and *o* are just clear of those on *d* and *e*. At the other end of *r* is the arrangement of two solenoids, &c., as shown in Fig. 3. In fact, *r*, in Fig. 4, corresponds to *d* in Fig. 3. *c*, Fig. 4, is turned by being connected to part of the moving gear of the engine.



FIGS. 4 and 5.—Further development of Carus-Wilson's Electric Governor.

Above and below the bearings *b b*, Fig. 4, are connections, as shown in Fig. 5. *a* in Fig. 5 is the shaft *a* of Fig. 4; *b* is a stirrup-shaped piece cut to take the screw on *a*. The other end of *b*, Fig. 5, forms a continuation of the gear between the valve and the governor, and there is an apparatus below similar to *b*, except that the screw is cut the other way.

Now, upon an increase or decrease of electromotive force one or other of the coils g^1 or g^2, Fig. 3, is brought into play as before described, and the top or bottom teeth, Fig. 4, clamp in those opposed to them, the result being that *a* is turned round one way or the other, and the two pieces *b*, Fig. 5, above and below are separated or drawn together, and the necessary regulation is effected at the throttle valve or expansion gear. The governor normally regulates the engine, but its action is supplemented if the electromotive force varies. Simplicity cannot be claimed as a merit for any of the above apparatus. The adjustments of the springs *l* and *v* in Fig. 3 must require the greatest nicety. The whole apparatus appears to be of too delicate a nature for the purpose required. The combinations, however, have the merit of novelty.



FIGS. 6 and 7.—Varley's Regulator.

No further specifications for regulating by controlling steam engines was filed to the end of 1882. This, therefore, completes the list of those under review. Before, however, quitting this portion of the subject of regulation, I must mention a patent of Mr. Varley's, No. 5665, of 1881. Mr. Varley claims for it "the use for controlling the speed of a motor employed to produce electric light," &c. In the patents hitherto mentioned the regulation was confined to governing steam engines. Mr. Varley's regulator, however, is intended to be used not only with steam engines, but with any motor, and would come under a more general heading of

Controlling Motors.

Fig. 6 shows the construction of what Mr. Varley calls the regulator magnets.

L is an electro-magnet, the poles of which, N and S, are tubular, and approach each other in the centre; M and M^1 are equilibrium springs; M^2 and M^3 are conductors, against which the equilibrium springs press; M^2 is attached to, but insulated from, the soft iron cylinder O; M^3 is in electrical connection with the soft iron cylinder; P is an adjusting spring attached to the end of the pivoted lever Q, which rests on a hook at the lower end of M^3, shown separately in another position in Fig. 7; P^1 is a screw nut, by means of which the required amount of strain on the cylinder O can be adjusted.

When this apparatus is in circuit the current passes through the conducting wire W, and divides itself through the electro-magnet L and the resistance shunt R on to the electric lamps Z; part passes through the insulated wire of the electro-magnet L, and through the spring M, to the conductor M^2, and thence to the insulated wire surrounding the soft iron cylinder O; from this the current proceeds *viâ* the metal of the soft iron cylinder through conductors M^3 and lever Q on to the contact spring T and through R^1 to the lamps Z. When the electricity developed exceeds the desired amount the soft iron cylinder O is raised, and the lever Q closes the circuit through the contact spring T^2. This spring T^2 is connected with the electric governor T^3, details of which are given in Fig. 8.

It is not clear from the context how the action of raising the soft iron cylinder is brought about. All that can be gathered from the specification is that the regulator magnet L has tubular extensions, with poles directed towards one another and approaching within a short distance. The soft iron cylinder O is mounted in these tubular extensions, and is there held in a state of equilibrium by springs M M^1 pressing in opposite directions. This explanation by no means makes the matter clear. I may add that I have taken the whole of the foregoing description nearly word for word from the specification.

But to return to the electric governor shown in Fig. 8. X is the revolving shaft of the motor, which communicates through the pawl and ratchet X^1 to the centrifugal governor levers. Y Y^1 are

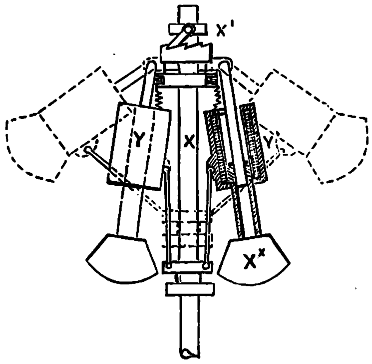


FIG. 8.—Varley's Electric Governor.

the tubular balls of the said levers. Y^1 is shown in section. When the circuit is closed through the helices of Y Y^1 the cores "become electro-magnets, and draw up the weights X^x as indicated by the dotted lines, thus cutting off the supply of actuating fluid from the prime mover (by closing the throttle valve)."

It is evident that when the weights X^x are drawn up the effect is "to reduce the diameter of the orbit through which the governor weights (balls) revolve, and by a well-known law it results that this rate of revolution becomes immediately increased, and consequently they travel round faster than the shaft which communicates motion to them. Thus the balls become raised by the centrifugal force, and the supply of actuating fluid to the motor is arrested by closing the throttle valve in the usual way."

No explanation is given of how the coils of Y Y^1 are brought into the circuit at T^3 (Fig. 6), but obviously there are many ways in which this could be done.

With regard to Figs. 6 and 7, the claim is for "the use for regulating electric currents of a soft iron cylinder, wrapped in two sections with insulated wire coiled in alternate directions, and mounted in a tubular electro-magnet in such wise that when the current exceeds a certain determined intensity the whole, or a portion of it, is diverted into a second circuit, substantially as and for the purpose described."

As regards the governor, the claim is for "the use for controlling the speed of a motor employed to produce electric light, or for other purposes, of a governor so constructed that the effective length of its arms can be altered when desired by the action of an electric current, substantially as described."

Both these claims appear to be novel, but whether such delicate apparatus is suitable for the purposes required of it practical experience alone can determine.

This brings to a close the section for apparatus for regulating by controlling steam engines and motors.

THE FINANCE OF ELECTRIC LIGHTING.

The contrast between the financial prospects and predictions of 1880-1 and the sober certainties of 1884 causes many of those who, in the earlier period, were full of confidence, to speak with mournful assurance of the "collapse of electric lighting." In truth, however, not only has there been no collapse, but there has been a steady and perceptible progress of invention and improvement. That which has collapsed are the avaricious fancies of those investors who allowed themselves to be misled by the glitter and unreality of representations that can only be characterised as fraudulent. So eager was the search for a good investment; and so robust was the faith in what was airily termed "electricity," that any one with a specification for lamp or dynamo found little difficulty in exchanging paper patents for hard cash. Now we have awoke out of sleep, it is the public who have acquired the experience and the promoter the money.

The concession of rights or franchises to supply cities and villages within a certain area with current on demand and at fixed prices was competed for helter-skelter by some of the shrewdest heads in the city of London. No one waited to inquire whether this thing, which was to revolutionise the conditions of life, was or was not feasible and financially profitable. It was assumed that the problem was solved, and the public backed its assumption to the tune of eight millions sterling. The actual state reached by electric illumination was recorded in the history of a couple of exhibitions, in which each exhibit was jealously watched by an army of trained supervisors, and by the achievement of a little public and private lighting, accomplished for the most part at a heavy loss to the the undertakers. Of further actual experience there was none. The daily press fostered the illusion, capital was got together, and so ended the first act of the comedy.

Expert witnesses, lawyers, promoters, accountants, directors, and patent agents were feed on a lordly scale. The workman who could turn up a commutator or could set brushes was paid his own price; but the outflow of money in those channels was found insufficient. "Free exhibitions" and installations at a loss furnished the vent which was needed, and those with rentals at the "price of gas"—whatever that may mean—contributed to the collapse of which we have spoken. But all is not yet lost. There are still some three million pounds uncalled from the shareholders. If the real business of profit earning is set about with open eyes and level heads it is still possible "*tout peut se retablir.*"

We have already dwelt on the legislative restrictions which obstruct the financial development of electric lighting. The letters from Mr. Arnold White and Dr. Fleming which appeared in a recent issue of *The Electrician* are unanswered, and, in our judgment, are unanswerable. But if the Act were repealed, and a measure substituted for it wisely conceived in the interests of progress, while protecting the rights of property, we cannot shut our eyes to the fact that we should be little nearer the desired end if other reforms of a more administrative character were deferred or neglected. The extended scale on which the companies were laid down is better fitted for grappling with the business of a State Department than the languishing operations of a retail trade. Rent of offices and works, directors' fees, and remuneration to staff for the most part were calculated on a turnover of capital which has failed to appear. Unless, therefore, legislative assistance is supplemented by a vigorous use of the pruning knife and an improved administration, no fact in physics is more certain than that the capital yet uncalled will follow the millions which have gone before.

There are in the directorate of the various companies individuals who would not only adorn, but would guarantee the success of any undertaking with which they were connected. On the other hand there are influences which—to speak with moderation—we can only regard with limited enthusiasm. Directors who are connected with a round dozen of companies cannot be expected to give that individual support, or make the resolute efforts without which no enterprise of so complicated and wide a scope as this can hope to succeed. The fact of a man undertaking the trusteeship of proprietors' interests in ten or a dozen companies at one time is a measure of the small importance he attaches to the performance of such duties. His efforts are diluted. "He spreads himself," as the Americans say, "too thin." When Stephenson was building the line to Birmingham he walked fifty-three times between London and the Midlands. Unless some such spirit as that of Stephenson animates those driving the coach, we may call until we are hoarse for a Board of Trade Hercules to pull our wheels out of the mud.

To sum up, electric lighting must be cheapened by a reduction in the permanent charges, *i.e.*, directors' fees, rent, and the cost of official staff. The administration must be seriously

Digitized by Google

undertaken by men who rate the difficulty of their task too highly to suppose that odds and ends of time are sufficient in which to accomplish the end in view. Too great stress cannot be laid on the fact that management which would ruin a butterman is not likely to organise victory for electric lighting. It is said that whatever money has been scraped together has been made up four pairs of stairs. Elevation of principle may not perhaps lead so high as this, but a new spirit of wise economy must permeate every department of electric lighting, or the champagne and glitter of the exhibitions will be the only things the country will remember of this effort to replace the existing method of artificial illumination.

CORRESPONDENCE.

ELECTRIC LIGHTING ACT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 5th inst. you invite expressions of opinion from your correspondents on this subject, but you have already so fully brought under notice the various points that there is little left to be said. Without doubt the interference on the part of the Board of Trade has resulted in almost total ruin of electric lighting. In no way can the Act be called anything else than a gas protection Act, and it has proved itself to be utterly restrictive to electric lighting. But now that this has been demonstrated, should there not at once be an agitation got up for the purpose of having it forthwith removed from the Statute Book? Why should not the electric light companies and those connected with electrical engineering unite together and form some sort of a protective society whose aim should be the repeal of the Act and the promotion of the welfare of electric lighting? And in this connection permit me to point out that although we may blame the Act for preventing the formation of central lighting stations for the lighting of shops, &c., yet what reason has prevented the adoption of the light in mills and other works? Nothing but its enormous cost. Although these places are provided with engine power, attendance, and afford every advantage for the working of the lights, we are prevented from lighting them owing to the exorbitant cost compared with gas. Had the directors of the different electric light companies who have had to go into liquidation been more energetic in getting the prices of the apparatus reduced to a reasonable figure, I venture to say that many of these companies would have been in a satisfactory working condition at the present day. To those who, like myself, have given up good situations to join electric lighting companies, it has been vexing to see so many opportunities thrown away. In this district alone thousands of lamps might have been working, and had these installations been carried out, it would have been the best evidence we could produce in approaching Parliament to show that the Electric Lighting Act is far too severe for any company to undertake the erection of central lighting stations on the terms required by that Act. I might give you the details of the provisional order granted for Dundee; but I am of opinion we all know the ridiculous terms of these orders too well, and that we have already given them more than enough of criticism. Our best plan now is to take action to get the Electric Lighting Act modified, and the prices of the apparatus reduced to a fair sum, so that we may be in a position to carry on an extensive business in mill lighting this ensuing winter, while our position may be under consideration by the Legislature.—Yours, &c., W. C. MARTIN.

Commercial-street, Dundee.

DYNAMOMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On Friday last, while looking through a note book belonging to Mr. Conrad Cooke, the last entry having been made in 1863, I came across a sketch of precisely the same arrangement as that described on page 202. Mr. Conrad Cooke cannot recall the source from which the sketch was taken, but I imagine the plan cannot be well known, as Mr. Kapp had not met with it in his researches on the subject of his very interesting communications.—Yours, &c., ALEX. P. TROTTER.

7, Furnival's Inn, E.C., July 15, 1884.

THE HEALTH EXHIBITION.—II.

The engineer decides that his governor must be very sensitive in order to comply with the demands of the electrician, and next to obtaining a governor that will act in advance, or simultaneously with the change, he provides one that acts almost simultaneously, so quickly, in fact, that it needs a trained eye to detect any lapse of time between cause and action. Another demand upon the engineer is that his engines shall run, without stopping, for a long number of hours at a stretch. This is no new demand, for marine engines are called upon to run almost continuously, but hitherto, with this exception, hardly any engine has been called upon to work so continuously as electric-light engines. Still further, in order to obtain economy, the engines are not only called upon to run and give out, not a nominal horse-power, but frequently a power almost or quite to their full capacity. Comparisons are odious, that we know, and it will be found that some of our most eminent engine builders have failed to please electric-light engineers. It would be interesting, for example, to have full details of the experience of the Brighton Corporation with their engine at the Pavilion. Without attempting to detract from the merits of the ordinary make of engine, we may say—and we would say it most emphatically—that a too great laxity has been shown by our prominent engine makers in the matter of electric light engines. This class of engine needs a special design, while too frequently all that has been thought necessary has been to dub the ordinary engine "good for electric light purposes." A new departure may be chronicled with the Fisheries Exhibition. Engineers learnt something from that exhibition, and have greatly profited by the knowledge so gained. How far the requirements of electricians have been met in the "Healtheries" Exhibition we hope to be able to show. Leaving, however, for the moment the prime motor, we must turn our attention to the intermediate part of the apparatus, viz., the dynamo. The dynamo, like the pump, must be made to fulfil certain conditions. Let us suppose, for instance, that we have a reservoir of water, into which the water has to be pumped by a pump actuated by a steam engine. Further, suppose the water runs out of the reservoir through one very long and comparatively small pipe, with portions at intervals still smaller than portions representing lamps in the electrical pipe or circuit. Suppose, further, the water is required to run out in a constant volume. We see at once this can be done only by the pump pumping the water to a certain height. The pump to do this work would not be constructed similarly to one required when the reservoir was tapped by a considerable number of pipes, all of similar section, it may be, to the pipe above mentioned, and each pipe containing only one small section. The former pump would have to raise a small quantity of water to a higher level, while the latter would raise a large quantity to a lower level. Dynamos have to be designed to do work something after this manner, for lamps, and especially arc lamps, are sometimes arranged one after the other along the same wire, to the tune of 10, 20, and up to 40. The dynamos built to supply lamps arranged like this—as the electricians say arranged in series— have so to speak to raise a small quantity of electricity to a high level (high potential). The dynamos built to supply the lamps arranged upon the other system—called the parallel system—that is, upon a number of parallel or practically parallel wires, each carrying one lamp, have to raise a large quantity to a lower level.

In visiting the Healtheries we shall feel small if, before talking with those in charge of the electrical apparatus, we do not make ourselves pretty familiar with some of their pet tech-

Digitized by Google

nical terms. Thus, to recapitulate, electricity which is analogous to water raised to a high level is said to be at a "high potential." Lamps put one after the other upon the same wire are said to be in "series;" most arc lamps are so placed. When the lamps are placed as in the diagram (Fig. 1) they are said to be in "parallel" or "multiple arc."

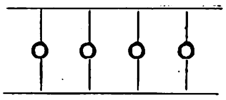

FIG. 1.

The dynamos to supply lamps in "series" are sometimes called "high tension" dynamos. An example of such a machine is the ordinary "Brush" dynamo. The dynamo to supply the parallel system is sometimes called a "low tension" or a "quantity" machine. An example will be found in the "Ferranti" or the "Edison" machine. Lamps are not always arranged so simply, but may be arranged in a combination of the two systems, and dynamos properly designed to supply such combination must be built. The Crompton-Bürgin dynamo may perhaps be cited as one used for such combinations. Thus far it has been attempted to show that the electrician in designing his dynamo must design it with a clear idea of certain work it has to do. He must, however, keep other ends in view besides the one we have so briefly discussed.

The wire which is employed to conduct the electricity—and which, in order to ease our explanation, we have looked upon as similar in the one case to the pipe used to convey the water in the other case—like the pipe, offers a resistance to the passage of the current. It is impossible with the most delicate of instruments to obtain indications of the phenomena called a current of electricity through some materials; in fact, some substances seem to be electricity proof, just as some are waterproof. Those substances which seem "electricity proof" are technically called "insulators." Thus resins, glass, gutta percha, india rubber, &c., are "insulators," though it may be well to say that it is doubtful if there is anything absolutely "electricity proof." Substances, on the other hand, which allow the phenomena of the "electric current" to be easily recognised are termed "conductors." Such are the metals, carbon, acidulated water, and so on. Some of these substances seem only to admit of the phenomena with difficulty—some seem to present hardly any opposition to the current. Silver and copper are among the substances that most easily admit the phenomena, and are therefore termed good "conductors," or substances having the least "resistance" to the current, while "carbon," "platinum," "iridium," "platinum-iridium," &c., offer great resistance, and hence are comparatively bad conductors. When the electrical current passes through a substance it, of course, heats it, and the heating power is some function of the resistance. The *same amount of current* per unit of time passing through a silver and a platinum wire of similar sections would make the platinum wire red or white hot, but would have no visible effect upon the silver wire.

The end we have in view is to show that the designer of dynamos must keep in view the "resistances" he has to deal with, some external to the machine, some internal. While this is the moral, a digression will be allowed in order to obtain familiarity with symbols and terms. Resistance, current, and potential have been mentioned. Difference of potential is called electromotive force. This latter is represented generally by E, the two former by R and C respectively. The relation between these was first determined by Ohm, and is therefore called Ohm's law, and is thus represented $C = \frac{E}{R}$, or $C\,R = E$, or $R = \frac{E}{C}$. No electrician can talk five minutes without referring several times to this law. The words italicised just now will be understood better by reference to the last formula, $R = \frac{E}{C}$. If R increases while C remains constant, then E must increase similarly to R; that is, if R is doubled, E must also be doubled, and so on. Using figures, $3 = \frac{6}{2}$, a fact understood by all who have mastered simple division. Here 3 is the quotient, 2 the division, and 6 the dividend. Keeping the division the same, and making the quotient 2×3, or 6, the dividend must become 2×6, or 12, in order that the answer may be correct, the whole being now written $6 = \frac{12}{2}$. The only figure remaining constant is 2. Now, E in electrical matters is analogous to the head of water, and if the head of water is constant while the section of the pipe varies, the current of water will vary; but if the current must be constant with a pipe of varying section the head of water must vary. A platinum wire of the same length and section as a silver wire has a much greater resistance, R. Therefore, if we take separately two similar pieces of these wires and attempt to send a current through them, we must, in the case of the platinum wire, have a current of greater electromotive force than with the silver wire if the current is to be the same in each case. Although at the risk of tiring some readers, we will attack this question in another way. Given two pipes—one connected to one cistern, the other to another cistern—the pipes being of the same material, length of section, and similarly placed in all respects, except that one pipe is partly filled with sand. The same quantity of water is wanted per minute from each pipe. It will at once be seen that the water in the cistern connected with the pipe partly filled with sand must stand higher than in the other, in order that the head of water may counteract the extra resistance to the passage of water given by the sand. So electricity must be at a higher potential, that is, have a greater electromotive force, when an equal current is required through a substance of greater resistance. If this verbiage has not helped to make the matter of how current depends upon electromotive force and resistance clear, we hope readers will turn to an elementary book on the subject, and continue the study till light is thrown fully upon the question, for, till it be comprehended, little real knowledge can be obtained about electrical apparatus. The electrician has to design his dynamo for the work it is to do. Suppose, then, it is to supply 20 lamps in series, and that the resistance of each lamp is represented by 10. As these resistances come one after the other, the total resistance will be the sum of the separate resistances (we put aside for the moment the connecting wires), or will be represented by $20 \times 10 = 200$. If the current required be 10 he must design a machine to give an electromotive force

$$E = CR = 200 \times 10 = 2{,}000.$$

The electrician will not give bare numbers like these, because he has a name for his units of current, &c. Thus, the unit of electromotive force is called a volt; of current, an ampere; of resistance, an ohm; and the above would be stated. A dynamo to give a current of 10 amperes through a resistance of 200 ohms must give the current with an electromotive force of 2,000 volts.

Looking at a dynamo, two binding screws will be seen, to which the ends of the external wire, or the wire carrying the lamps, are fixed. These are called the terminals of the machine, and it is the difference of potential between these two points that gives the electromotive force. The electricity, comparing it again with water, is as it were piled to a great height at the one terminal, called the + or positive terminal, while the − or negative terminal represent the low points, similar to the low level to which the water runs. Representing the high potential by P, and the low by P^1, then $P - P^1 = E$. When talking about water, the level of the sea is accepted as a datum line; and if a head of water is 100ft. above this, and connected by a pipe to a piston 100ft. below it, the pressure upon the piston is that due to 200ft. of water. The datum potential adopted by electricians is the potential of the earth; but when we deal with dynamos, the potential at the − terminal is generally as much below the zero potential as that at the + terminal is above it. Thus, to get $E = 2{,}000$, the designer would so arrange matters that $P = 1{,}000$ and $P^1 = -1{,}000$, so that $P - P^1 = 2{,}000$.

DYNAMO-ELECTRIC GENERATORS.

We have received from America the report of Mr. Sprague, of the United States Navy, on the Electrical Exhibition at the Crystal Palace. This is hardly the place to ask why we are indebted to America for this admirable report. We are glad that someone has performed the work our own Government or the authorities of the Crystal Palace should have performed. Professor Adams, in his inaugural address to the Society of Telegraph Engineers, gave an excellent abstract of this report, but was of course compelled to pass over without much notice some parts of it. We have thought that some extracts, supplementary to Professor Adams's paper, will prove interesting to our readers. Thus:—The Crystal Palace Electrical Exhibition was the second of a series which is likely to embrace exhibitions in most of the great commercial centres. Following close upon that of 1881 in Paris, it did not promise, in its early stages, to be very successful, either as a commercial enterprise, or as a scientific exhibition of new discoveries and important progress. Despite the activity of invention, it seemed improbable that any great advance had been made in the short time intervening between these exhibitions such as to warrant the organisation of the second. But the Paris Exhibition had served to make prominent that electric lighting was becoming a reality, a new branch of industry was proved successful, gas and the arc light had found a rival, and the great strides made in perfecting the incandescent lamp and developing a system for domestic lighting were awakening not only scientific but popular interest. The many evils attending the use of gas as an illuminant promised much for a means of lighting which would offer any advantages.

The arc light, after several years' trial, while fairly successful in some places, and under certain circumstances, has too many inherent defects to prove generally useful, and its displacement is only a matter of time. Two years ago Henry Draper said that he would not be surprised if we were on the eve of a great change in electric lighting; that the incandescent lamp would entirely take the place of the arc light.

Although this change has not yet come, it is, I think, certain to do so, and my reasons for so thinking will later be evident. It may be thought that on account of the present inequality of light economy between arc and incandescent lamps, an intermediate form, the semi-incandescent lamp, would be the more acceptable because of its steadiness and brilliancy, but in practice and theory certain disadvantages become apparent which negative this idea. The incandescent lamp thus becoming of such importance, any exhibition which would serve to awaken invention, stimulate healthy competition, and enlist public interest and capital would in the end prove successful, both in a scientific and commercial point of view, and such the exhibition at the Crystal Palace finally proved to be, despite the disadvantages of its origin. It was not designed solely for the purpose of electric lighting, especially in the domestic form of application, but was intended to embrace a great variety of inventions in all the different forms in which electricity could be made use of. These were embraced in the following classes:—

I. Static electricity.
II. Batteries and allied apparatus.
III. Magneto-electric and dynamo-electric machines.
IV. Cables, wires, conductors, and allied apparatus.
V. Apparatus for measuring electricity.
VI. Telegraphs, signals, and allied apparatus.
VII. Telephones, microphones, and photophones.
VIII. Electric lighting.
IX. Electric motors and transmission of energy.
X. Electro-medical apparatus.
XI. Electro-chemistry.
XII. Magnets, compasses, horology, instruments of precision, &c.
XIII. Miscellaneous.
XIV. Generators, steam, gas, and hydraulic engines, &c., applicable to electric industries.

Nearly three hundred exhibitors took part, each exhibiting in from one to seven classes. In several of the divisions there was an excellent collection, but in some others very little of importance. Especially so was this the case in Class IX., where there was no evidence of any material progress. This is to be regretted, because the transmission of energy is destined to play a part second only, if even that, to electric lighting. In fact, the two will often go hand in hand. Hence, as far as this exhibition is concerned, electric lighting, especially in the domestic form, was of the greatest interest and importance, and, in view of the necessary character of this report, I shall confine myself almost entirely to such part of the exhibition as relates to this subject. I shall not generally describe exhibits as a whole, but will consider the merits of individual machines, lamps, and systems, discuss the theory of the dynamo machine, investigate the demands of a system of electrical distribution, consider the application of the electric light to men-of-war, and describe our experimental work. And in so doing I shall take what I consider the most important examples.

History of the Dynamo-Electric Machine.

Let me briefly review the history of the development of machines for converting the energy of motion into that of electricity.

In 1831 Faraday, reasoning from the remarkable discoveries of Œrsted, Arago, Sturgeon, and Ampère, was led to make a series of experiments for the purpose of evolving electric currents by the mutual action of closed circuits and magnets, and in the latter part of the same year made public the theory of the "lines of force" or the magnetic field, which is now recognised as determining the action of all electric machines. Not only is the magnetic field present in the case of iron or steel, but it surrounds every conductor in which flows an electric current. Three years after the announcement of the theory of magneto-electric induction, no less important than the laws of electro magnetism which had preceded it, Lenz announced a law which may be enunciated as follows:—That the currents induced by the relative movements of closed circuits and magnets, or of two closed circuits, are always such as to produce mechanical forces tending to stop the motion which produces them.

Pixii was the first to make a practical machine embodying the principles set forth by Faraday. This was in 1832, when he brought out a machine in which he revolved a permanent magnet in close proximity to the ends of soft iron cores, around which were wound coils of wire. He was followed in quick succession by Saxon, Clark, and Page, and later by Wheatstone and Cooke, all of whom invented machines in which the currents were produced by the mutual action of magnets and soft iron, one or the other being surrounded by a coil of wire.

In 1842 Elias produced a machine which is the forerunner of some very successful machines of the present day. This consisted of two rings with six projections on each, one ring being inside of the other, and the projections of the outer ring facing towards the centre, and of the inner ring outwards. The intervening spaces were wound with wire, the direction of winding being reversed in alternate sections. A current being passed through the coils, the projections became poles of a compound ring magnet, alternating north and south. Consequent attraction and repulsion with rotary motion resulted, and when the polar extensions were opposite each other the direction of the current in the coils of the inner ring was reversed, changing the poles, and thus keeping up the rotation, there being as many reversals as there were polar extensions on the ring in one revolution. This machine, however, was designed as a motor, and was not used for the generation of a current.

Then came Schottlaender, Stöhrer, and others, with modifications of the Pixii machine, using a large number of magnets and coils. In 1845 it occurred to Wheatstone and Cooke to use an electro-magnet instead of a permanent one, and this was excited by a battery. Nine years passed, and then Hjorth made a decided advance by designing a machine with a combination of permanent and electro-magnets, such that the current induced in the revolving coils by the permanent magnets was made to excite the electro-magnets, the first

Digitized by Google

attempt at self-exciting. In 1856 the Siemens armature was made, consisting of a long cylinder of small diameter, with two longitudinal grooves cut in it, and filled with wire. In the same year Holmes brought out an improved Alliance machine, consisting of a number of coils on a disc, rotating in close proximity to a number of permanent field magnets, and in 1862 this was used for lighting the Dungeness lighthouse.

In 1858 some unknown person proposed to use the whole of the current generated for the purpose of, in whole or in part, exciting the electro-magnets. About thirty years had now elapsed since Faraday's announcement of his discovery, and all the efforts made had only resulted in producing machines embodying the principles of the first, and depending upon the magnetisation and demagnetisation of magnet cores. Partial self-excitation had also been made possible, and true auto-excitation shadowed forth.

The year 1860 marked a new discovery or invention, one which is the prototype of a large number of the best modern dynamo machines, but which was, like the Elias invention, intended for a motor. This was the design of Pacinotti, which was publicly described four years later. The most interesting and important feature is what he calls a "transversal electro-magnet." This is a ring of soft iron, enveloping which is an endless spiral of wire. Supposing the ring and spiral cut and straightened, there would be an ordinary electro-magnet, with strongly marked poles at the extremities, when a current was passed through the wire. If the ring be again formed, the ends of the coil rejoined, the poles would be no longer apparent, even supposing a current circulating. That is, it would be a closed magnetic circuit. If, now, the wire at two extremities of the diameter of the ring be denuded, and contact be made at these points by the terminals of an otherwise complete circuit, the current would divide and pass in opposite directions around the two halves of the ring. There would then be developed two unlike poles, one at the point where the current entered and one where it left; that is, there would be formed a ring magnet, which might be considered as composed of two semi-circular electro-magnets, placed together, like poles to like. If the current were allowed to enter or leave at the extremities of any other diameter, poles would be as readily formed at these points. Now, by taking a wire from each bight, or coil, to a small piece of metal on the axis, and ranging the pieces in the same order as the bights, two strips of copper could be made to traverse successively the strips, if the ring were made to rotate and the points of current entering and leaving, and consequently the poles of the ring could be made to travel around the ring progressively. This was mounted on a spindle, and placed between the poles of an upright electro-magnet, and the connections were such that the current was passed through the magnet coils and the ring coils in series, as in many dynamo machines. The ring was provided with projections between the coils to bring the poles nearer to those of the electro-magnet. The brushes, which rested on the commutator strips, were so placed that the poles should be formed so as to cause attraction and repulsion. A current being passed through this machine rotation ensued, and the position of the poles in the ring shifting as fast as the ring rotated, they maintained a fixed position with regard to the electro-magnet. The effort of rotation was something like that of a man on a treadmill.

The reasons given by Pacinotti for constructing this machine were as follow:—

1. That according to this system the electric current is continually traversing the coils of the armature, and the machine is kept in motion, not by a series of intermittent impulses succeeding one another with greater or less rapidity, but by a constantly acting force producing a more uniform effect.

2. The annular form of the revolving armature contributes (together with the preceding method of continuous magnetisation) to give regularity to its motion, and at the same time reduces the loss of motive power through mechanical shocks and friction to a minimum.

3. In the annular system no attempt is made suddenly to magnetise and demagnetise the iron core of the rotating armature, as such changes of magnetisation would be retarded by the setting up of extra currents, and also by the permanent residual magnetism, which cannot be entirely eliminated from the iron; and with this annular construction such changes are not required, all that is necessary being that each portion of the iron of the ring should pass in its rotation through the various degrees of magnetisation in succession, being subjected thereby to the influence of the electro-dynamic forces by which its motion is produced.

4. The polar extensions of the fixed electro-magnet, by embracing a sufficiently large number of the iron projecting pieces on the armature ring, continue to exercise an influence upon them almost up to the point at which their magnetism ceases when passing the neutral axis.

5. By the method of construction adopted, sparks, while being increased in number, are diminished in intensity, there being no powerful extra currents produced at the breaking of the circuit.

Dr. Pacinotti further pointed out that when rotating a continuous current was generated in opposition to the battery current. By replacing the electro-magnets by permanent magnets and rotating the ring mechanically the machine would generate currents of electricity.

The direction of the current generated was reversed by reversing the direction of rotation. That of the machine was reversible. One of Pacinotti's machines, a copy he made, was exhibited at the Crystal Palace. Twenty years have passed since this inventor made these discoveries, and it has only been in recent years that he has received at all general recognition for his remarkable discovery. It may be interesting to note the resemblance existing between the Pacinotti ring and that invented by Elias nearly twenty years before.

Two years after the publication of the system of winding and commutator connections devised by Pacinotti, Baron Worms de Romilly patented systems of winding the armature of electric generators, embracing two entirely distinct methods, one of which being the forerunner of the Gramme, and the other of the Siemens or Hefner-Alteneck system.

In the first of these the coils were wound so as to entirely enclose an annular or cylindrical shell, which rotated between outer and inner permanent magnets. In the other, the coils were wound longitudinally along a cylinder, opposite parts of a coil being on opposite sides of the cylinder.

A modification of the first method was a flattened ring, the active parts of the coils being radial, and the magnets being placed at the sides or ends of the ring. A commutator was proposed, but it does not seem to be like the Pacinotti type, for all the coils have the current changed at the same time.

In 1866 and 1877, Varley, Wheatstone, and Siemens, independently, and practically simultaneously, announced in different ways the discovery of the self-exciting principle, one of the most important for practical purposes; and in the latter year Wilde built a machine in which he used a large and small armature, the smaller rotating between the poles of a permanent magnet and exciting the larger electro-magnet. In the same year Ladd devised a machine with two armatures rotating between opposite ends of the same electro-magnets, one supplying the exciting circuit, and the other the external circuit.

We have now come to the year 1870. Most of the machines devised in the forty years following Faraday's discovery, although ingenious, had defects which made them impracticable for the demands of electric lighting, and they generally, if not all, depended on the mutual action of magnets and soft iron—that is, upon the sudden magnetism or demagnetisation of cores which were surrounded by coils of wire. The currents while energetic were really suddenly created or destroyed; the commutation of such alternate currents was accompanied by great sparking and waste; the continuous current resulting was made up of a series of powerful impulses, and there was a great amount of heat developed in the magnet cores. A few of these machines have been since developed into practical generators, but may be considered as obsolete. The Romilly patent had suggested the longitudinal cylinder coils, the radial and ring coils, and the labours of Pacinotti most distinctly pointed out the way for the prac-

Digitized by Google

tical construction of a truly continuous current machine, and the reversibility of electro-motors and generators.

The principle of self excitation from the residual magnetism of soft iron had also been established; yet with all this experience it was not until six years after the publication of Pacinotti's work that a really continuous current practical electric generator was brought forward, and in a short time developed into a pure dynamo with self exciting electro-magnets. And the credit of it is due to M. Gramme.

The year of 1870 marks a new era in the progress of electrical science, and one in which the advance has been very great. Gramme was followed in 1872 by Hefner-Alteneck with a new and ingenious and highly powerful type of machine, now familiar under the name of the makers—Siemens. Then came the labours of Lontin, Farmer, Wallace, Lachaussée, and De Meritens on the older form of machines, of whom the latter is the most successful; and of Weston, Farmer, Maxim, Edison, Brush, Seeley, Bürgin, Schuckert, Heinrichs, Gülcher, Jablochkoff, and a score of others beside; the continued labours of Gramme and Siemens, on the newer forms, or on machines involving to a greater or less extent the main principles of construction and working of the Pixii, Elias, Pacinotti, Romilly, Gramme, and Siemens generators.

I will first give some account of the principles governing the generation of electricity, and a general classification of machines, reserving for individual notice more detailed accounts of the construction and theory of action of such of the modern machines as were exhibited at the Crystal Palace.

Principles and Classifications.

Broadly speaking, an electric generator is a machine for converting mechanical energy into electrical energy, and such conversion is made by the influence of a magnetic field on the conductor of closed circuit. That there may be any such influence brought into operation it is necessary that there should be a change in the magnetic field with respect to the conductor on which it operates. If such a change of magnetic field is made, then a current will be induced in the conductor, whose direction and strength of energy is determined by the quality and amount of change. Every magnet—and we may say that all iron is more or less magnetic—and every conductor in which a current is flowing is surrounded by a magnetic field, and the object desired is to make the most effective use of the strongest field.

We know that when a wire encircles a mass of iron, if the magnetic state of such iron is changed, electric energy is immediately made manifest in the wire, but disappears at the instant the change is completed. So, too, if a conductor is moved in proximity to a wire which is conveying a current, a current is induced in it, depending for its direction on the relative motion of the wires and the direction of the inducing current. Or if two wires are near each other, and a current is established or broken, or its strength changed in one, a current is induced in the other. Again, if a conductor is made to pass the end of a magnet, a current is established in it whose strength and direction is dependent upon certain conditions. Now, what causes all these currents, and why do they change in direction and strength? To follow Faraday's description, a magnetic field may, for all practical purposes, be considered as made up of lines of force. In the case of the free magnetism apparent in iron these lines may be looked upon as lineal. By this I do not mean that the vibratory or vertical movements of the ætheric medium, which conveys electrical manifestations, take place in right lines, for the vibration has probably a spiral or rotary character; but rather that if mapped out, say by means of iron filings, the resultant would show magnetic efforts taking place in lineal directions. These lines are not parallel; but, considering one pole of a magnet, diverge, seem to repel each other, and take the most direct path possible, their divergence and the intervening medium being considered, to the opposite pole. The field surrounding simple conductors is either rotatory or spiral in character. In the case of iron this field may be much changed and intensified by the introduction of a mass of iron, through which the lines of force seem to pass most easily. If a conductor is so moved that a line of force is crossed, a current will be induced in it, and the greater the number of lines cut in a given time the greater will be the activity of the current. The action of conductors upon each other, and of iron upon wire surrounding it, although dependent upon the production of a magnetic field, does not seem so clear; and although I have formed ideas concerning it, I will not attempt their discussion. In the ordinary magnetic field the number of lines of force cut in a given time depends upon the strength of the magnetic field, direction of motion of conductor, velocity of the conductor, and the strength of the current further depends upon the length of conductor. If, then, a generator depends entirely upon the motion of a conductor in a fixed field, the field should be made as strong as possible, reasonably speaking —as much of the field as can be should be called into play; it should be intensified and made regular by the introduction of iron near the magnetic poles; and a long conductor should move at a high velocity at right angles to the strongest field.

So, too, with magnet cores does intensity of current depend on rapidity of change, strength of magnet, length of convolutions, and their proximity to the core.

On the other hand, the object of a generator is to produce a current where chiefly required in a part of the conductor outside of the machine, that is in an external circuit. We have, then, to consider which of the elements useful in producing electric action are disadvantageous.

Just here, however, let me speak of the quantities we have to deal with. These are simply—Electromotive force, current, resistance. The first is what is called into play by the motion of a conductor in a magnetic field, and is the force which tends to make a current circulate in a conductor. It exists in a battery at rest as well as when in action, and may be certainly regarded as in existence in a conductor moving in a field, even though the circuit is not closed. It is a potential, an unequilibrium of electric energy, which, on a path being formed, tends to equalisation. If such a path is opened, energy is immediately made manifest in the form of current, a transition of ætheric vibration over a conductor. This current is dependent upon two elements, the E.M.F. or potential, which is endeavouring to restore equilibrium, and a third quantity, resistance—that quality of a conductor which opposes the free electrical vibration. These quantities, or qualities, are mutually dependent, or rather the current may be better considered dependent on the other two. If expressed as an equation this relation becomes Ohm's law,

$$C = \frac{E}{R}.$$

A current passing over a conductor always does work, and the amount of this work is determined by the strength of the current and the resistance offered in its passage. With a given resistance it varies as the square of the current; with a given current it varies with the resistance. Now the work done appears in the evolution of heat, and unless the heat can freely radiate, the conductor and any metallic masses in contact with it must rapidly heat. If long conductors are used in small spaces they must take the form of convolutions superposed one on another. Hence it becomes necessary to depend to a great extent upon high speed and strong magnetic fields rather than upon length of conductor, when moderate electro-motive forces are produced. Where high external resistance must be overcome the high speed and magnetic field are insufficient, and then long conductors must be used. But where those high electromotive forces are used the currents are small, as in the transmission of energy over long distances, and, on the other hand, in practical work, such as electro-plating and incandescent lighting on the multiple arc system, low electromotive forces are attended by heavy currents.

High conductor speed may be obtained either by a high angular velocity—that is, by a large number of revolutions per minute, or by large dimensioned moving parts. To the first there is of course a limit, and this limit is the more quickly reached if the moving parts are driven directly from the source of motive power, instead of through the medium of

Digitized by Google

belting and gearing. On the other hand, compactness and handiness of parts put a limit also to the size of these, and a medium must be struck depending upon the circumstances under which a generator is to be used.

(TO BE CONTINUED.)

ELECTROLYSIS OF SULPHURIC ACID IN ACCUMULATORS.

Some time ago Professor Frankland suggested that in charging and discharging accumulators hexabasic sulphuric acid was electrolysed. Dr. Gladstone and Mr. Tribe have carried out some experiments in this direction with sulphuric acid of a strength of 4·2 per cent. Their apparatus consisted of a U tube having a stop cock in the centre of the horizontal portion. The hole in the stop cock was so packed with asbestos as to prevent mechanical mixing of the liquids in the two arms of the tube or endosmose. With currents of different strengths they notice that the increase of sulphuric acid in the positive compartment per equivalent of hydrogen set free decreased with the lowering of the current strength. In other experiments with sulphate of copper in one arm and sulphuric acid in the other, they found that the acid accumulated was largely in excess of the copper deposited, this being due to the unequal transference of the ions. From these results and those obtained by other experimenters, they conclude that the electrolytic method is incapable of determining whether dilute sulphuric acid, H_2SO_4, or a hydrate thereof, gives rise to the current; and moreover, from other experiments with copper and zinc sulphates, in which both arms of the U tube were filled with the same solution, they show that neither the composition nor even presence of a hydrated salt in aqueous solution can be determined by this method.

THE IRIDIUM INDUSTRY.*

By WM. L. DUDLEY, Cincinnati, O.

It is my desire to call attention to a new industry which was started about four years ago, through the discovery by Mr. John Holland, a resident of this city, of methods suitable for working the metal iridium. This metal has been known since the year 1803, having been discovered by Smithson Tennant while investigating the metallic residue which remained when platinum ores were dissolved in aqua regia. The metal is classed among the rare metals, as it is not found in large quantities, although it is quite widely distributed geographically. It is found in California, Oregon, Russia, East India, Borneo, South America, Canada, Australia, and in certain parts of France, Germany, and Spain. The principal sources of supply of the metal are Russia and California; it is nearly always found with either platinum or gold, is extracted from those ores as a by-product, and is always found in small grains or fine powder, the largest pieces being about the size of a grain of rice. In nature it is generally alloyed with other metals, and the two metals with which it is most commonly alloyed are platinum and osmium; the platinum alloy is called platin-iridium, and the osmium alloy osmiridium, or iridosmine. The grains of platin-iridium are sometimes found as small cubes with rounded edges, while the iridosmine usually exists in the form of flat irregular grains and occasionally as hexagonal prisms. The supply of metal which is derived from Russia is generally obtained from the platinum mines which are situated in the Ural Mountains; while in California it is found principally in the placer gold-washings. The ores of iridium are a source of great annoyance when mixed with gold dust on account of its specific gravity, which is about 19·3, being nearly the same as that of gold. Consequently, it is impossible to separate the gold from the iridium by the process of washing; the separation may, however, be made either by the amalgamation of the gold (as neither iridium nor its ores combine with mercury) or by dissolving out the gold in aqua regia.

In the mints these metals are frequently separated by melting the gold dust and allowing the molten mass to remain in the crucible for some time, during which the iridium slowly settles to the bottom, as it does not alloy with the gold under such circumstances. The gold is then poured off from the top, and the dregs in the bottom of the crucible are found to contain the greater quanity of the iridium. The gold contained in the dregs is then dissolved and the iridium is found in the residue.

In Russia it is contrary to the law to possess or deal in iridium ore, and consequently the Government takes possession of all the ore which is mined or extracted from the platinum ores in that country, and it is stored in the vaults of the Royal Mint. The reason for the law is, that some years ago the Russian Government found that speculators in gold-dust would sometimes add iridium to it (which often escaped detection by the officials of the mint), for the purpose of increasing its weight. On attempting to work this gold they found the fine particles of iridium distributed through the ingots; on rolling the ingots into sheets, these individual grains or particles produced indentations in their steel rolls; and in striking out the coins the dies were marred and defaced, thus causing considerable loss to the Government. In order to prevent this species of fraud, the Government passed a law prohibiting persons from handling the metal in any way and compelling its immediate surrender.

For a number of years experimenters have endeavoured to melt the iridosmine or iridium in order to utilise it in the arts for such purposes as could with advantage employ a metal of its wonderful properties; but until lately success has been only partial.

I may here briefly describe the properties of the metal itself. Iridium possesses a white lustre, resembling that of steel; its hardness is about equal to that of the ruby; in the cold it is quite brittle, but at a white heat is somewhat malleable. It is one of the heaviest of metals, having a specific gravity of 22·38. When heated in the air to a red heat the metal is very slowly oxidised; but upon raising the temperature to about 1,000 C. it parts with its oxygen, and hence at a high heat (above 1,000 C.) it is not oxidised. It is insoluble in all single acids, but is very slightly soluble in aqua regia after being heated in the state of fine powder for many hours. In a massive state, however, aqua regia does not attack it.

In attempting to fuse iridium heretofore, it has been found by experimenters that the best results that could be obtained were by means of the oxyhydrogen or electro furnaces, but that with either of these means of fusion they could only work a very small quantity of the metal at a time, and obtain a globule of very small size. Previous to the present time iridium has had substantially but one use (with the exception of alloying with platinum), viz., for pointing gold pens. The iridium point is commonly called "diamond point" upon a gold pen, and it consists simply of a small grain of iridosmine which has been selected for the purpose, and soldered to the tip of the pen. These are selected by first removing from the ore, with a magnet, the magnetic oxide of iron which always accompanies it, and then dissolving out, by means of acids, the other impurities which may be present; the ore is then washed with water, dried, and sifted in order to remove the fine dust, and the sifted ore is then ready for the selection of points. This is done by an operator, who rolls the grains of iridium around with a needle point, examining them under a magnifying glass, and selecting those which are solid, compact, and of the proper size and shape. These points are usually selected in three grades, small, medium, and large, depending upon the size of the pen for which they are intended to be used. The grain of iridium having been soldered on to the end of the pen, it is sawn in two (which makes the two nibs of the pen), and ground up in the proper shape.

About four years ago Mr. John Holland, the well known gold pen manufacturer, found it necessary to have pieces of

* Read at the Cincinnati meeting, American Institute of Mining Engineers, Feb., 1884.

Digitized by Google

iridium larger than those generally found in nature for the purpose of making points for the Mackinnon stylographic pen. After many experiments he found that by heating the ore in a Hessian crucible to a white heat and adding it to phosphorus, and continuing the heating for a few minutes, he could obtain a perfect fusion of the metal, which could be poured out and cast into almost any desired shape. This material was found on physical examination to be about as hard as the natural grains of iridium; and in fact seemed to have all the properties of the metal itself. On chemical analysis it was found that the metal fused with phosphorus contained, according to two determinations, 7·52 per cent. and 7·64 per cent. of phosphorus. At this stage of the discovery we became acquainted with it, and began experiments with the intention of putting the product to some practical use in the arts. It was found that the presence of phosphorus rendered the metal quite readily fusible at a white heat, but this, of course, was an obstacle in the way of its use for electrical purposes. Desiring, therefore, to remove the phosphorus, we found by experimenting that by heating the metal in a bed of lime the phosphorus could be completely removed. In this operation the metal is first heated in an ordinary furnace to a white heat, and finally, after no more phosphorus makes its appearance, it is removed and placed in an electric furnace with a lime crucible and there heated until the last traces of phosphorus are removed; the metal which then remains will resist as much heat without fusion as the native metal.

In mechanical applications, where the metal is not subject to great heat, it is melted with phosphorus and cast into the shape desired, and then ground or worked as the application may require. The first application to which it was put was for the manufacture of the Mackinnon pen-points. For this purpose, the metal, after being fused, is removed from the furnace and poured between two slabs of iron which are kept apart the desired distance so as to make a sheet of iridium of the thickness required. The metal is poured, as I have said, between these plates, and the plates are brought suddenly together on the plan of a closed ingot with a hinge, so that as the metal cools it is subjected to pressure which closes the pores and makes a very compact casting. The slabs for the Mackinnon pen-points are about one thirty-second of an inch in thickness, and are broken up into small irregular pieces, which are soldered on a strip of brass, and ground down to a flat surface by means of a copper lap. The copper lap consists of a plate of copper, about one-half inch in thickness and eight inches in diameter, fixed on a spindle, which is made to revolve from eight hundred to a thousand revolutions per minute. The copper of which the lap is composed is wrought copper, well annealed, and consequently very soft. In order to grind with it, corundum or diamond dust is mixed with oil and applied to the flat surface of the lap by means of a flat steel instrument, upon which pressure is applied in order to force the corundum or diamond dust into the copper, thereby making a cutting surface. The iridium to be ground is held against this sharp surface of the lap, and the corundum or diamond dust gradually cuts the metal away. As the cutting material wears from the copper lap, another application of the corundum and diamond dust is made by means of the steel instrument as described; this operation is continued until the grinding is complete. After the slabs are ground to a surface they are then drilled. In the drilling operation, the iridium is first countersunk by means of a diamond drill, consisting of an upright spindle suitably fixed in a frame so as to revolve freely; the bottom of the spindle holds a small rod of brass, to the lower end of which is set a white diamond-splint. This drill is made to revolve about nine hundred revolutions per minute. The iridium is held up against the diamond with a light pressure, and the diamond gradually makes a conical hole or countersink. After countersinking the iridium, it is finally pierced by means of a copper drill, which consists of a piece of soft copper wire, which is filed down to a point and set in a drill similar to that in which the diamond is placed, but this drill makes about thirty-five hundred revolutions per minute. Corundum or diamond dust and oil is put into the countersink opening in the iridium, and then it is held up against the piece of revolving copper. The diamond dust or corundum, embedding itself in the copper, acts as a cutting surface, and finally accomplishes the drilling of the hole. The holes having been drilled in the pieces of iridium which were soldered to the brass, the brass is finally dissolved from the iridium by means of nitric acid, and then we have irregular-shaped pieces of iridium, pierced with holes. These pieces of iridium are then soldered in proper position to the end of the Mackinnon pen, fitting into the opening of which there is a valve consisting of an iridium-pointed wire. The iridium is then ground to the proper shape on the outside by means of a copper lap, consisting of three or more copper cylinders on a common spindle, making about three thousand revolutions per minute.

The operation of sawing iridium is carried on by means of a copper disc, from four to eight inches in diameter, made of soft thin sheet copper, held between two clamps, placed on a spindle revolving at the rate of about twenty-five hundred revolutions per minute. This sheet of copper revolves in a box which contains corundum or diamond dust and cotton-seed oil. The cotton-seed oil with the cutting material adheres to the periphery of the saw, and as the saw comes in contact with a piece of iridium it gradually does the work. Cotton seed oil is preferred for this purpose to any other oil, on account of its viscosity.

I may mention briefly some of the uses to which iridium has been applied. First, I will refer to the draw-plate for drawing wire. There are at present, besides the iridium draw-plate, the ordinary steel plate which is used for drawing heavy wire, and the ruby plate, which is used in drawing gold and silver wires, where it is desirable to have them of uniform thickness. The iridium plate is made somewhat similar to the ruby plate, consisting of a piece of iridium which has been countersunk and drilled in the usual way to the size of the hole required, and set in a brass plate, where it is firmly held by a bushing. This plate is now coming into use, and is rapidly taking the place of the ruby plate, being equal to the ruby in hardness and much more durable, since it is less liable to break or chip by rough handling or heating.

Iridium knives are made for fine scales and balances, the bearing edge of which consists of iridium, soldered firmly to a brass body. These are rapidly taking the place of the agate for fine chemical balances, and there seems to be no reason why they should not have even a more extended use, since they are superior to the agate in that they take a finer edge and thereby make a more delicate balance, and are not so liable to crack or break. They are now being used altogether by Mr. Henry Troemner, of Philadelphia, the well-known scale manufacturer, for the purpose of adjusting his weights for all of his scales.

Hypodermic needles for physicians' and surgeons' use are now made of gold and tipped with iridium, in place of the old steel pointed ones, which are liable to rust or corrode if not properly taken care of. The iridium being hard will take a good edge, and is not subject to corrosion, as is steel.

Styluses for manifold writing are also being made with iridium points, having decided advantages over either steel or agate. Iridium points are also being applied to surveyors and engineers' instruments, and in all places, in fact, where hardness, durability, and non-corrosibility are required. For all the above uses the iridium alloyed by fusion with phosphorus is employed.

Some years ago experiments were made in order to apply this metal to the electric light. We found that an iridium electrode used upon the negative of an arc light would keep its shape and resist the heat, provided the positive carbon which was used with it was not allowed to strike or fall too heavily upon the iridium negative. Since the metal at a white heat becomes malleable, a continual pounding or striking would gradually beat the negative out of shape. The iridium negatives are made by setting a piece of dephosphorised iridium in the end of a brass rod about six inches long and nine-sixteenths of an inch in diameter. The length of the iridium is about half an inch, ground conical in shape. It was found that the brass, being only half an inch from the arc, would resist the action of the heat; but in some cases where the lamp flamed the brass was liable to undergo partial fusion; and in such cases it was found desirable to put a thimble

Digitized by Google

or cap of platinum over the end of the brass and just below the iridium, the platinum thimble being about half an inch long.

One of the most important applications of iridium which has yet been made is to the electrical contact-points of telegraphic apparatus. These contact-points consist of pieces of copper wire tipped with iridium, which are set in the instrument just as platinum points are set. These contacts will outlive many platinum contacts, are not subject to oxidisation or sticking as are the platinum ones, and all that is necessary in order to clean them when they become dirty is to pass over their surface an emery file or a piece of fine emery paper. These contacts have been thoroughly tested by various eminent electricians and also by long-continued use, and the advantages herein stated have been in every case fully demonstrated.

In the past three years we have been experimenting on methods of plating with iridium, and about one year ago we succeeded in obtaining a bright reguline deposit of iridium on base metals. This deposit resembles the natural metal, being quite hard, and resisting the action of acids. There were many difficulties encountered in accomplishing this result, on account of the power of the metal to resist the action of the solvents; but we have succeeded in obtaining a solution which gradually attacks an anode of iridium, and it is hoped in a short time that all the minor practical difficulties will be overcome in the plating of articles on a commercial scale. So far, we have been thoroughly testing our results, and do not feel prepared to place our work before the public until it is perfect in all its details.

LEGAL.—The Universal Electric Company (Limited).

In the Court of Session, Edinburgh, on the 12th inst., before the Lord President and Lords Mure and Shand, a note was presented to the First Division, on behalf of Thos. Wilson, accountant, Glasgow, and Alex. Murray, C.A., Glasgow, joint liquidators of the Universal Electric Company (Limited), asking the authority of the Court for the removal from the list of contributories of the names of David Corse Glen, Robert Sorley, and David Whyte, the liquidators being satisfied that those persons were not properly entered upon the register of shareholders, and that the company could not succeed in establishing liability against them. Authority was also asked to give effect to certain compromises proposed to be effected by the liquidators of claims against certain debtor-shareholders of the company.

The Court sanctioned the deletion of the names requested, and continued the other matter contained in the note until the following week.

Counsel for the liquidators: Mr. Shaw. Agent: John Gill, S.S.C.

The Direct United States Cable Company (Limited).

Report of the directors for the six months ending June 30, 1884, to be presented at the fourteenth ordinary general meeting of the Company, to be held at the Cannon-street Hotel, Cannon-street, on Friday, 25th July. With this report the directors submit the usual statements of account for the half year ending June 30, 1884, which, with the half year's accounts to 31st December last, presented at the ordinary general meeting on the 8th February last, show the financial result of the seventh year's working of the Company. The revenue for the half-year, after deducting out-payments, amounted to £68,573 8s. 11d. The working and other expenses for the same period, including interest on debentures and income tax, but exclusive of cost of repairs of cable, amounted to £19,750 2s. 10d., leaving a balance of £48,823 6s. 1d. as the net profit of the half-year, making, with £3,524 8s. 6d. brought forward from the previous half-year, a total of £52,347 14s. 7d. Three quarterly interim dividends of 1¼ per cent. each, amounting to £45,532 10s., have been declared and paid at the usual times during the financial year, and a final dividend of 5s. per share is now proposed, making, with the three interim dividends, 5 per cent. for the year, being a total distribution of £60,710. The appropriation of the above balance of £52,347 14s. 7d. on the revenue account is thus shown:—Interim dividend for quarter ending 31st December, 1884, £15,177 10s.; final dividend now proposed, £15,177 10s.; carried to reserve fund, thereby increasing it to £360,000, £19,030 15s. 11d.; final balance of liquidation expenses, £175 10s. 1d.; carried forward to next account, £2,786 8s. 7d.; making a total of £52,347 14s. 7d. The interruption in the short section of cable mentioned in the last report has been repaired, and the cost of the repair, £5,127 18s. 9d., has been charged against the reserve fund. The final meeting of the liquidators, closing the liquidation and dissolving the old company, took place on the 17th ult. The repayment of the £100,000 six per cent. debenture loan will be made on the date due, viz., 15th October next.

Two of the directors, Messrs. William Ford and C. J. Gunther, retire by rotation, and being eligible, offer themselves for re-election.

Mr. John G. Griffiths and Mr. John Sawyer, the auditors, retire by rotation, and offer themselves for re-election.

West Coast of America Telegraph Company, Limited.

The Directors present to the shareholders the accounts for the year ending 31st December, 1883, showing the gross revenue to be £57,338 12s. 1d., against the sum of £38,908 2s. 10d. for the previous year, or an increase of £18,430 9s. 3d., and leaving a net balance of profit, after paying debenture interest and all other charges, of £23,314 9s. 7d. The Board declared in January last a dividend of 4 per cent., or 8s. per share, which absorbed a sum of £12,000 out of the net balance of £23,314 9s. 7d. The remainder has been absorbed in forming a reserve fund, and in discharging the last of the liabilities caused by the war and the consequent cessation of the Company's business. The reserve fund amounts to a nucleus of more than £10,000. Since the 31st December last the Board announce a further improvement in the position and prospects of the Company. For the six months ending the 30th June the receipts amount to the sum of £25,850, or—including the sum of £4,400 received from the Chilian Government—£30,250 against a sum of £23,450 for the corresponding period of last year, showing an increase for this year, so far, of £6,800. Out of this the Board have declared a dividend for the half-year at the rate of 4 per cent. or 4s. per share, which will absorb a sum of £6,000. This dividend is payable on the 25th inst. Mr. Matthew Gray having resigned, the Directors have elected Mr. Henry Roberts in his stead. The members retiring by rotation are Mr. R. Kendal and Mr. H. Roberts, both of whom offer themselves for re-election. The auditor, Mr. J. Weise, retires, and is eligible for re-election.

COMPANIES' MEETINGS.

Eastern Telegraph Company (Limited).

The twenty-fourth half-yearly ordinary general meeting of this Company was held on Thursday, July 10, 1884, at the City Terminus Hotel, Cannon-street, London, under the presidency of John Pender, Esq., M.P.

The SECRETARY (Mr. Draper) read the notice convening the meeting and the minutes of the last two meetings, which were signed by the chairman.

The directors' report having been at the request of the meeting taken as read,

The CHAIRMAN said: Before submitting the resolution for the adoption of the report, I wish to give you a little further information on the different items in the report. The details given, however, are very full, as I dare say you will all admit; still, there are some points that I should like to refer to. Our revenue for the six months ended 31st March last amounted to £345,156, against in the corresponding period of last year £328,404, being an increase of £16,752. This increase is largely due to the expedition undertaken by the British Government in the Soudan and the continued occupation of Egypt by the British troops; also to the gradual development of the general traffic. As to the expenses, the ordinary working expenses of the half year amounted £90,482, against in the corresponding period of 1883 £87,827, being an increase of £2,655, which includes a charge of £2,410 for expenses as to the issue of the 4 per cent. debenture stock. The increases and decreases are shown as follows:—The general expenses in London show an increase of £528. This is caused by increased law expenses in this period in connection with the action brought against the Company by the Central News Company, judgment for which has been given in our favour. The working expenses at the stations show an increase, but several of the other items show decreases. These expenses, however, include the working of two additional stations, viz., Suakim and Glasgow. A greater number of clerks have been home on leave of absence and sick leave, necessitating more changes among the staff between one station and the other. The depreciation of cable stores shows an increase of £210. A larger stock of cable had to be depreciated this year than last. The expenses of electrical exhibitions were £446. In connection with the cholera in Egypt the expenses were £101, and there are other items making up this increase. But, on the other hand, there is a decrease in the following items:—For use of patents, £6; foreign agencies, £445; maintenance ships' reserve fund, £1,000; staff endowment assurance, £77. The important point is the expenses attending the repair and renewal of cables. That amounted to £37,113, against £50,901 in 1883, or a decrease of £13,788. We carry to the general reserve fund £65,000, making that sum with interest on investments £614,170. From this amount, as explained in paragraph 5 of the report, the directors have applied the sum of £300,000 in part payment of new cables, leaving the general reserve fund at £314,170. The total amount of reserve funds, including the Sardinian cable and other special reserves, is now £349,777. The investments against this, as shown in Abstract D, are £328,574. In addition to this, £100,000 had been previously taken from the fund in part payment of expenditure on the Aden-Bombay duplicate cable. I may mention that taking the £400,000 from the reserve fund instead of adding it to capital, taking it all round, it is something like a saving to the Company of £10,000 a year, which is available for dividend, and which would not have been the case had we not taken that sum. Since the amalgamation of 1872, the ordinary working expenses have averaged nearly 26 per cent. of the revenue, and the repairs have averaged 11 per cent. The average cost of repairs to cables since 1872 amounts to £55,000 per annum, or something like £3 per mile. The total working expenses, including the expenses of the four maintenance ships, have been about 37 per cent. The average amount carried to reserve fund has been £50,000 per annum. The number of stations in 1881 was 42, and in 1884 it was 50. The number of the staff at the stations in 1881 was 419, and in 1884 the number was 533. There

Digitized by Google

are six grades or classes among our *employés*, and the average salary of each man, excluding superintendents, is £109 per annum. The following cables have been laid since March, 1881: the Malta and Tripoli, 204; the Trieste and Corfu, 303; the Alexandria and Port Said, 153; the Suez and Aden, No. 3 cable, 1,402; connecting Suakim, 178 miles, making a total of 2,440 miles. The present length of cable, including the Black Sea, is about 19,000 miles, and the land lines about 3,000 miles. That is a very remarkable growth in the history of your Company. As you remember, there were some opinions expressed when we issued our £500,000 of debentures.

The SOLICITOR: Debenture stock.

The CHAIRMAN: Debenture stock. That stock was issued partly to pay off the 6 per cent. debentures, and partly to pay amounts which were incurred in the extension of the lines I have just mentioned to you in that 2,000 odd miles. Some thought it was a very bold thing to issue 4 per cent. debenture stock, but I am very happy to say that every shilling of that stock has been taken up, and more would have been taken up if we had had it to allot. I think it will be interesting to you to know how we have dealt with that £500,000, as the more information we give the more I am sure you will appreciate the position. Over expenditure of capital prior to September, 1881, required £28,090; redemption of 6 per cent. debentures £232,000; additions to new buildings at Suez, £3,983; Trieste and Corfu cable, £66,935; Malta and Tripoli cable, £29,268; Alexandria and Port Said cable and Suez Canal and other land lines, £36,799; Suez-Aden triplicate cable and the Suakim diversion £317,716; new stations, £812; increase of stock of cable in hand, £9,850; Direct Spanish Telegraph Company's shares, £39,237; Mediterranean Extension Company's shares, £3,498; addition to working capital invested in spare cable, £6,806, less taken from the reserve fund £300,000. On the other hand, we have spent £775,000. Taking the £300,000 from the reserve fund, that amount is brought down to £475,000, out of the £500,000 of debentures. I think all these figures give you a pretty good idea of the financial position of the Company, and although I have given you all these figures, and you have been given very full details in the report, I think it occasionally my duty to refer to one or two points in the report. As you are aware, we have established two new stations. One is at Glasgow. It may strike some of our shareholders as going a little out of our way to establish a station there; but a very large extent of trade is done between Glasgow and India, and the result of our having established our telegraph wires is that in many instances the telegraph goes to India as quickly as to London under the old system, and in these times, when telegraphy is measured not by hours but by minutes, we cannot be one minute behind when merchants' interests are at stake. We have also a station at Liverpool, and we find that they have answered the purpose immensely well, and have been very great boons to commercial interests there. The next station we established was at Suakim. There is a long history about that, but I will not go into details. I hope, however, that you will see that there was some foresight shown in connection with that matter. We laid down a third cable in the Red Sea at a time when some people thought it was not required. I believe even some of the members of the Government in our correspondence with them thought it was not desirable; but had we not laid down that third cable in the Red Sea we should not have been able to carry one of those cables into Suakim, thus giving the Government and the country an enormous advantage of telegraph communication with Suakim later. I think that is a very important feature in the history of the management of the Company, and we have no reason whatever to regret taking our cable into Suakim, as it has given us a very fair return, besides, as a gentleman by me has just remarked, having made the Government feel that they cannot do very well without us. That is the real fact. When any important war takes place, almost the first consideration is—can we be placed in telegraphic communication with a particular place? And we are always ready to do the work when the work can be done in the interests of the Company and the country generally. The next point I have to mention is that when I last addressed you I mentioned we had made arrangements with the Greek Government for the completion of their system. It is all but completed. I can scarcely give you the names, but there are twenty-five islands now connected, which you see mentioned here (showing map). Those twenty-five islands we have connected in Greece for the Greek Government, and I think I may pay a compliment to the intelligence, and I would say the patriotism of the man now at the head of the Greek Government in placing the islands of Greece in connection with Athens by a most perfect telegraph system. Probably there will be no better telegraph system in existence when this is completed. One of the results of our visit to Constantinople in the autumn was that we have got a concession from the Turkish Government—what we call the Salonica concession—which gives us in the Mediterranean and the Levant a very strong position indeed. I need not go into any details as to that further than to say this—that this concession secures us, as long as we can do the work as well as anyone else, the doing of it. I should have mentioned when I alluded to Suakim that the Government contemplate a railway from Suakim to Berber. If that is done there is no doubt that Suakim will be a port in the Red Sea, and a very important port too. I only wish that I could say that peace was established in the Soudan, but the business is in hand. England in the past has always fulfilled her obligations, and I trust that England in the present and in the future will continue to do so. If those obligations are carefully and fully carried out, there is no doubt that that connection between Suakim and the Red Sea will be a very important system for developing the commerce of that vast continent, and commerce firmly established and properly conducted is the best security for peace in the future.

We have also had another business to deal with during the last six months, securing what I would call a preponderating interest in the Direct Spanish Company. There is a very important telegraphic communication between Spain and this country, and that was an isolated company; it stood alone. It was too small to do a great deal for itself, and still it was one of those systems we could combine and utilise with very considerable economy in our system. In the meantime, it is considered desirable to keep the Company distinct, and they have duplicated their system. For doing that they have issued debentures at 6 per cent., and we have considered it not a bad bargain, seeing that it is practically in our own hands, to exchange with the manufacturers of the cable who have got those 6 per cent. debentures. We have arranged with the Telegraph Construction Company, who manufactured and laid the new cable, to exchange our 4 per cent. debentures for their 6 per cent. debentures. I think that is not a bad transaction in the interest of the Company, seeing that it adds another important link to our telegraph system.

The next point I wish to mention is as to the Mediterranean Extension Company. That was another small link in those waters that we have got possession of. As we sat down at the Board meeting in the next room we received a telegram from Italy stating that the whole thing is completed. My notes said the thing was approved by the Government, but not yet approved by the Parliament; but the telegram that we have received is to the effect that it is approved by the Parliament. That is another very important link in our system which I think we shall turn to good account. I have spoken of the issue of £500,000 of debenture stock at 4 per cent., and I would say that that shows that our credit has been very high in the money markets of the country.

I promised when I last addressed you that, as to our connection with Egypt and the Red Sea, I might give you this time some valuable information. The valuable information is that we have completed all this system, and we have a very sound footing in Egypt, and an equally sound footing in the Red Sea. Our relations with the English Government and the Egyptian Government are such that as long as we continue to do the work in the future as we have done in the past (and I hope we shall always continue to do it better than any new company could), you may rest assured that our position is safe in commanding the traffic of the two countries. I think I need not say more on that, and I think you may be satisfied that what we have done has been done in a way to secure the best interests of the shareholders. I have another matter to refer to which will probably interest you. During the last three years (I stated that we were taking that average) the amount of work done by the Company has been almost startling. During that period the average of paying words has been 10,300,000 per annum. Just conceive what an amount of labour is required to convey those 10,000,000 words! The non-paying words for which we are not paid in our telegrams amount to 3,000,000, or a total of nearly 14,000,000 words transmitted every year during the last three years, making a daily average, including Sundays, of 38,300 words. Now, I looked at this extraordinary traffic for two reasons. First, you can conceive how much we are in the hands of the young men who are employed to convey those messages. In the second place, you can well understand during a time of war what the difficulties of maintaining this system are. And the reason I draw your attention to the subject is, not only to ask your sympathy, but the sympathy of the press and the general public, for our working under the trying circumstances in which we have been frequently placed. I allude to this to-day for the purpose of bringing before you the suit raised against us in the courts, as to which I believe you have nearly all got a copy of the evidence, which after many days' sifting placed us, I think, in a very proud position [hear, hear]. Showing you, as I have done, the difficulties we contend with, the wonder is, looking at the fact of the frequent attempts to tamper with our men, that the thing has come out as pure and satisfactory as it has. I must admit that I sympathise with a man who thinks he is first and finds he is second; but when I look at the amount of press correspondence—the pressure that is in every way brought to bear on the system—you must come to the conclusion that only one can be first; and it is very hard for that one, however well satisfied he may be that he was first, but it is very hard for us also, having two or three cables to work, that we should be forced to such enormous expense as we have been to defend an action of this kind. We have tried to keep our system as correct as possible by the business men you have. We have felt and had confidence in most of our young men; but if any gentleman, whether a press correspondent or another man, attempts to demoralise our men by giving them money to get priority of information, it rests with them and not with us, and they are not the people to come and attack us for doing what they consider an unfair thing to them. I think I have not said a hard word against those who have been suing us. It is done at enormous expense, and causes considerable anxiety, because my friend and your managing director, Sir James Anderson, has been placed as few men have been, and I think you will all agree with me that after seven days' investigation, and the decision of the Lord Chief Justice, he has no reason to be ashamed of holding up his head. I am told that the business is not at an end yet. I am sorry for it, and sorry for the gentlemen who are taking all this trouble; but let them bear in mind what I have said—let them do the best they can, and give us some little credit, as we desire to give them credit, for doing the thing well. It is better than going into litigation. No money can be so badly spent as in the way they are spending money at the present time.

I think I have gone fully into the affairs of our Company. Our ships at the present moment are not employed—that is, they are well employed when doing nothing, as far as the interests of the Company are concerned. But we have to keep them thoroughly equipped, so as to go at an hour's notice when any work requires to be done. With these remarks, I beg to move the following resolution:—"That the printed report and accounts of the directors to 31st March, 1884, submitted to this meeting, be and they are hereby received and adopted; that a dividend on the preference shares of the Company to the 30th of June, 1884, at the rate of 6 per cent. per annum be paid, less income tax; and that in accordance with the

Digitized by Google

directors' recommendation a dividend be and is now declared of 2s. 6d. per share, with a bonus of 1s. per share, both free of income tax, on the ordinary shares of the Company, making with previous payments by way of dividends on account a total payment of 6 per cent. on those shares for the year ended 31st March, 1884."

The VICE-CHAIRMAN (the Marquis of Tweeddale): I beg to second that.

The CHAIRMAN: Before I put that motion to the meeting, if any gentleman wishes to put a question on the report, or any remarks I have made, I shall only be too happy to answer him.

Mr. DELONERGAN: I was not here when you commenced, and I have not perused this report. I see a large sum down for the laying of the third cable in the Red Sea from Suakim. I think it is from Suez to Suakim. Am I right? £300,000 it is. One would imagine that would not pay.

The CHAIRMAN: I think, sir, you have not quite listened to my observations.

Mr. DELONERGAN: I told you I was not here at the commencement of the meeting. I merely wish to ask you if there are any collateral advantages for laying that cable beyond the more traffic that will accrue from laying it, as it appears to me that by and by if peace is established it would not pay by traffic to Suakim. I wish, therefore, to know if you have any collateral advantages in consequence of laying that cable from the Government, or otherwise. I wish also to ask you if you intend to discontinue those service messages, which will create a certain amount of suspicion as long as they are continued. No one should have an advantage over another. It appears to me that the practice of those service messages brought you all this trouble and litigation that you have gone through. With great respect I will suggest that you had better discontinue them altogether. The public will have more confidence in what they are paying for. I am sorry to see that our dividend is not larger, after having all the traffic that we have had in this Company. Six per cent. appears a small thing after all the traffic you have carried, and I suggest that you should cut down the expenses as much as possible.

Mr. HURST: I think it very unfortunate that the last speaker was not present or did not attend to the chairman's remarks. If he had been we should have been spared his remarks. We have listened to and heard with great interest the chairman's speech, and I never here or anywhere else heard anything more satisfactory. The manner in which the business has been transacted—an immense business, a business of such extent that there are few in the world equal to it, to be conducted in the manner in which this has been is highly creditable to everyone concerned in it. The wonderful thing is that mistakes are not made and that such a business can be carried on with the immense amount of regularity with which it has been. A gentleman spoke of the dividends. I would say for myself—and others, I believe, would also say, remembering the past—that I think the dividend is satisfactory. Some years ago—not a great many—when we were receiving 5 per cent., the chairman held out some expectation of a slight increase. I put the question then to him whether we could not look forward to 6 per cent. The chairman shook his head and spoke doubtfully, and spoke of a small increase, but you see that that for which I expressed a hope has been fully realised, and I trust if we can go on with such a business as this receiving a constant 6 per cent. we shall do exceedingly well. If we can get our business into a sound and steady state, not like where you have a great dividend one time and none at another time, I think that that would be a matter for congratulation. This business has been conducted so well, and in such an economical manner, that the dividends seem to be perfectly steady and satisfactory. If we can go on increasing in prosperity, there will be a possibility of something additional being made; but, if that should arise, I should say that it had better come in the shape of bonus than in any increased dividend, because if you give an increased dividend, and it cannot be maintained, there is a great deal of stock-jobbing, and steady investors suffer a great deal from it. Altogether, I think we may congratulate ourselves that we hold property in as sound and substantial a business as any in England, and I trust it will continue in that way. I think the warmest thanks are due to the directors for the energy and judicious manner in which the business of the Company is transacted. As to the third cable that has been spoken of, the chairman fully explained that it had turned out profitable. With regard to economy, considering the responsibility we throw upon the *employés* of the Company, and considering the average payment they receive, I think that none of them are overpaid. I think we may sit down satisfied and feel that we are on the way to a very good business.

Mr. GRIFFITHS: A very able speech has been made to us by our chairman, and I think there is very little room for questions. I would only make one suggestion; it is founded on the last portion of our chairman's speech, as to the very unfortunate litigation into which we been dragged. I say dragged, because we are the defendants, not the plaintiffs, and I believe all the right is on our side. We are successful so far, and I hope we shall be, but no doubt heavy bills of costs will be incurred. It may be that our opponents are not men of great wealth, and if we gain the costs we may not be able to recover them. Having attended the court very frequently, and having heard most of the evidence, I have come to the conclusion that, while we are guiltless, possibly the military authorities exceeded the power which they ought to have exercised. No doubt the military ought to have the first information conveyed by the telegraph; but I think it is going a little beyond their right when they not only obtain it themselves for military purposes, but make use of it for other purposes. I wish our opponents would attack the Government rather than us.

The CHAIRMAN: Will you allow me to suggest that as this case is not yet settled, the plaintiffs having stated they will appeal, let us be generous as well as just, and not discuss the matter?

Mr. JOHN NEWTON: The gentleman who spoke before Mr. Griffiths seems to be satisfied with 6 per cent. I am not. I do think, while I endorse all the eulogiums he has bestowed on you as to the management of the Company, that 6 per cent. is not a very fair return for the capital we have invested in this Company, and also for the immense service this Company is rendering to the world at large. When we find railway companies that have not rendered great services to the community paying 8, 9, and 10 per cent., I think we ought not to be satisfied with 6 per cent. I think from the manner in which you are managing this Company's affairs that we are within sight of an increased distribution, and as to whether it should be dividend or bonus, it will be the same in my pocket whichever it is. We must not, however, be satisfied with 6 per cent. In addition to the capital there are large reserves, which all add to the strength of our Company, and I think we ought to have 6 per cent. on a capital so solidified as this.

The CHAIRMAN: A gentleman who spoke referred to the desirability of abolishing what are called "service messages." If we abolished service messages we ought to shut up our stations altogether. We manage our business by service messages, and to abolish them is impossible, and if you had sat in my seat I think you would never have uttered such a suggestion. It requires a great deal of knowledge and experience to conduct such a system as this. I am sure you have all sympathy with Mr. Newton's remarks. I have. If we go on, if we do a good deal of work, and with the property pretty well solidified, we shall begin soon to sit down and think whether there is anything further to be done. We see the end pretty well, and when we get all that in order Mr. Newton may depend that that which he sees looming in the future will be a reality. We are putting £50,000 a year to the reserve fund meantime, and if we are not putting the money into your pockets, we are in that other way strengthening the position of the Company.

Mr. DELONERGAN: You did not answer one of my questions, whether you have got any collateral advantages from the Suakim cable.

The CHAIRMAN: I made a speech in which I stated that it had already pretty well paid itself, and further that we had got such a collateral advantage that it placed the Company in such a position that, if we do the work in the future as we have done in the past, we shall be likely to have possession of that part of the sea for our submarine cable. I cannot say more. I think I have satisfied the body of shareholders that they are in a very sound position. I wish to give every gentleman a full opportunity of expressing his opinion. Last year the directors stated in their report:—"The directors have concluded an agreement with the Egyptian Government by which this Company engage to connect Suakim with Suez by one of their Red Sea cables." And the present report says:—"The connection of Suakim with Suez and Aden has been effected in accordance with the agreement entered into between her Majesty's Government, the Egyptian Government, and the Company. It is not my business to give you the minute details of this agreement. We consider they belong to the management of the Company; but we should not have put that in the report unless a satisfactory arrangement had been come to.

He then put the motion for the adoption of the Report in the usual manner, and declared it carried unanimously, and intimated that that concluded the business of the meeting.

Mr. GRIFFITHS: Mr. Chairman and gentlemen—I think we can hardly conclude the business of the day without expressing our thanks to those who have managed for us so well. I am sure Mr. Pender's speech gave us very full and very useful information; and this question of our friend, although it might be a good one, was answered before it was put. It requires no ordinary talent to conduct such a business as this, with its capital of over five millions, and its messages of over fourteen million words a year. And it is surprising that so few mistakes, if any, occur. For this successful conduct of our business we are under great obligations to our chairman. We need not discuss here the career of our chairman. It is most interesting to read how that gentleman has risen so high in the world, and has done so much for us. To us the increase of dividend is most satisfactory, and the prospect held out that Mr. Newton's hopes will be realised in time to come must be satisfactory to us all. I hope Mr. Pender will long preside over us.

Dr. WALLER: I have given way to the gentleman who most properly proposed this vote of thanks. I never rose with more pleasure in my life at a public meeting than to-day to second a resolution. Your speech, Mr. Chairman, gave us all great pleasure. It was, as it always is, lucid. It was exhaustive, and most thoroughly satisfactory. There are two or three things that have given us great pleasure. One is the question of the Suakim cable. You explained all about it as far as you could, but you did not go as far as to say anything that would be improperly discussed before a public meeting. We have great reason to congratulate ourselves on the issue of the 4 per cent. debenture stock. I will not detain you any longer, for we have been detained a long time. I shall only address myself now to one question—that is, the propriety of increasing our dividend. I am greatly satisfied with that dividend, and I hope whenever the time comes that we shall pay an extra amount it will not be in the way of dividend, but in the way of bonus as heretofore. There is no better financial barometer.

The SOLICITOR put the motion, which was carried.

The CHAIRMAN: On behalf of my colleagues and myself I have to return you our thanks. I think I can see in the feeling that has been taking place during the last two or three years increased confidence on the part of the shareholders in the management of the Company. I am proud to see that. It is what we desire above all things, and you may rest assured that as we come to our half-yearly meetings we shall keep nothing hidden from you that we think you are entitled to know; if, at any time, it should be that we have kept back anything that we ought to have brought before you, we shall stand arraigned before you. We shall give you all the information we can. I think I may say, during the sad times we have been passing through, when every stock almost in the country

Digitized by Google

has been falling, ours has not only stood the test, but has positively advanced. That is another assurance to us and another evidence to us of the position we occupy. Taking that and the issue of our 4 per cent. debenture stock enables me to say that an investment in this Company may be reckoned among the very best investments in this country or in the city of London. I beg to thank you.

The proceedings then terminated.

United Telephone Company (Limited).

The fourth annual ordinary general meeting of this Company was held on the 15th inst., at the offices, Oxford-court, Cannon-street, under the presidency of Mr. James Brand.

The SECRETARY (Mr. Thomas Blaikie) read the notice convening the meeting, and the report of the directors was taken as read.

The CHAIRMAN said: It is now my duty to make a few remarks to you, but I will detain you as little as possible. I think it may be convenient to say a word as I go along on the different heads alluded to in the report. First, as to capital, we have expended during the year £53,604. This has been spent as follows:—£26,378 in the London business, £13,326 on instruments distributed all over the country earning royalties, and £14,000 in stations worked by ourselves, such as Bristol, Southampton, Brighton, Ipswich, Norwich, and various places in South Wales which have not yet been made over to subsidiary companies. These companies are, however, in course of formation, and when completed will repay us the whole of our outlay in accordance with the arrangement already adopted with other companies we have formed. Meantime, they are doing very well, and have become valuable adjuncts to our business. You will have noted with pleasure that, with the above expenditure of £53,600, our revenue has increased £27,500, while our working expenses show an increase of only £5,500. I think also that you will feel that we are now grappling in earnest with the important matter of depreciation, although we are still without reliable data on which to form our calculations. We have written off over £15,000 this year. The dividend speaks for itself, and I hope you are satisfied. You may think that we might have squeezed out a little more, but our business is still in its infancy, and we never know what surprise may be in store for us, and so we think it much better to make up a good reserve account. We have therefore decided to add £10,000 to our reserve, and carry forward £5,000. This will make, with reserve, against depreciation, over £60,000, which I consider getting towards a substantial amount. As regards the progress of our business, we should have liked it to have been more rapid, but on the whole we must not complain, looking at the generally depressed state of trade all over the kingdom. This has caused the withdrawal of some of our subscribers, and no doubt prevented others from joining our exchanges. During the whole of this year, also, another company has been doing its best to prevent the public from joining our system by offering to give them exchange facilities for £10 instead of £20; but for all this, we have been able to fill up vacancies caused by removals, and to show a very substantial increase, as shown in our revenue account. Then, as to relations with the General Post Office, we have alluded rather fully to this subject in our report, and since that I have been again in communication with the Postmaster-General, who has pledged himself personally to take all our matters in hand, and I hope with a real wish to remedy our grievances so far as is consistent with his duties. I have in this matter to thank many Members of Parliament who have interested themselves in telephone matters on behalf of their constituencies and the public. We have had a very busy and eventful year. We fully advised you of what had been done in the first six months in our circular of the 12th February last. Since then, I am sorry to say, we have been rather busy with law, and we have won two or three important actions against infringers, which has greatly strengthened our hands. We have also had law forced upon us by the Wandsworth Board of Works and the authorities at Bristol, who took proceedings against us in the matter of our overhead wires in their districts. We don't blame them for taking this course, but we were bound to defend our position, and the result has been this: In the Wandsworth case, which was tried first, Mr. Justice Stephen, while deciding that our wires there were not a source of danger or a nuisance to the streets, decided against us that we were technically trespassers on the property of the Board. This would have left matters in a very unsatisfactory state, and we accordingly went to the Court of Appeal, who gave judgment unanimously in our favour. The effect of this is that the authorities must be able to show fairly that danger exists before our wires can be meddled with. The result of this decision has been that negotiations have been entered into, which we hope and expect will lead to a friendly and reasonable settlement in other cases. So far as this goes it is sufficient for the present. The telephone companies, carrying out their business as they do in the interest of themselves and the public, are of course most anxious to meet every requirement of the authorities—not only for the safety of the public, but also to avoid rousing even their susceptibilities. We have already done a great deal to minimise all possible danger by rearranging in every possible case our scattered wires, and running in their stead single cables containing not less than twenty wires. These cables are suspended to strong wires from pole to pole, and also by treble wires in the heart of the cable, so that it is almost impossible that they can fall. On these cables have been expended large sums of money during the last twelve months, and this greatly accounts for the heavy outlay on capital account, while we have only as yet received a very small advantage from them. I think, however, you will find the benefit of them in future balance-sheets. We quite agree with all thoughtful people that matters cannot rest where they are, and to this end we have used every effort to pass through Parliament a Bill for the proper regulation of overhead wires by a competent central authority, such, for instance, as the Board of Trade. We would gladly put all our wires under ground, but as I pointed out at our last meeting, this is for the moment simply impossible. Indeed, notwithstanding a letter that appeared last week in the *Pall Mall Gazette*, I don't think we have yet sufficient experience to prove that an exchange system on a really large scale can practically be worked underground—at any rate, in a city like London. The expense is so enormous, and, as I said at our last meeting, the crowded occupation of our central thoroughfares is so great that they cannot be used for fresh undertakings, especially in view of the wires for the electric light, which must be put underground if they are put anywhere. With regard to trunk wires connecting our exchanges in different towns, I am very sorry I cannot tell of much progress. The position taken up by the General Post Office is so difficult and impracticable that we have found it useless to struggle on with it, and preferred to do almost nothing and wait the result of our present negotiations than commence this branch of our business on the lines now laid down by the Postmaster-General. We hope these negotiations will come to a satisfactory issue, which would immediately result in an immense development of telephonic business, and I believe without doing any injury to the telegraph revenue of the Post Office. With regard to our Bill in Parliament for the regulation of overhead wires, while the Government were not indisposed to go into the whole question, they would not allow us to press forward a Bill on our own account, or introduce a Bill of their own while litigation was pending with regard to the present powers of the local authorities in the matter. No other point occurs to me, but I shall be pleased to answer any question, and, in the meantime, let me congratulate you and myself on meeting for the first time in our new building, which is a standing monument of our substantial advance in prosperity. You can see for youselves how quiet and secluded it is in the very heart of this busy city, and, therefore, how suitable for our business in every way. In conclusion, I must tell you that I have not words at my command to express to our managing director, Mr. Joseph B. Morgan, the grateful acknowledgments we would wish to offer to him for his untiring devotion and self-sacrifice in the interests of us all, and for his invaluable services in the promotion of the use of the telephone. One word more. Mr. Morgan's efforts and all our efforts would have been of no avail had he not had at his disposal the entire devotion of a staff of assistants whose hearts and brains were entirely wrapped up in this enterprise. And I take this opportunity to thank them heartily. And last, but not least, let me thank your legal advisers, Mr. Winterbotham and Mr. Crisp. They have not only given us their own most valuable services, but they have been successful in obtaining for you in all our contests the aid of four of the most eminent counsel at the bar, who have never for one moment left us in the lurch or neglected your interests; and although we have had to pay large sums of money for legal assistance, every shilling has been well spent and honestly earned. I will now conclude by moving the following resolution:—"That the report and accounts be received and adopted, and that a dividend for the half year ending April 30, 1884, of 5s. 6d., free of income tax, per fully paid £5 share (part paid shares receiving in proportion) be now declared."

The DEPUTY CHAIRMAN (Mr. J. S. Forbes) seconded the motion, which, he said, he felt sure would be received with unanimity. He had very few words by which to supplement the speech of the chairman, who, however, had left him a few plums. "The proof of the pudding is in the eating," and what they were very much concerned in nowadays was that there should be no mistake as to whether their implement was an implement of great social and commerical value. There seemed in some minds some doubt of that even now, as one could hardly imagine—if the view which they themselves took of the matter was correct—that a great public department could be indifferent to it, or could be blinded to the fact that the public sooner or later would insist upon having the use of a means so valuable as the telephone. Besides the department referred to there was a great deal of misunderstanding about it. He was very often surprised to find men of the greatest intelligence who never appeared to have considered how they could add to their own comfort and the efficiency of the way in which they conducted their affairs by the use of the Company's instrument. That morning he had been in a great establishment, and to his surprise he found no telephone about the place. He said to the manager, "I do not understand you. You have your relations all over London, all over your own establishment, and you use enormous time, and undergo great discomfort in doing that which you could with the telephone do instantly with perfect ease." He himself was able to sit in Victoria-street, and with the use of the telephone he could make all his business dovetail in; and, in fact, what used to be a difficult thing was now perfectly easy and certain by the use of the telephone. Persons could communicate with each other and arrange business, and get business conducted in the course of an hour or so, while under the old system it took the whole day. Their progress, notwitstanding the immense advantages they offered, was not as rapid as they could wish, but still it was very substantial. Four years was a very short time for an enterprise of that kind to be in existence. In the first year, ending with April, 1881, they had 914 subscribers on exchange lines, and there were 943,000 calls; while in 1884 the number of subscribers had increased to 3,350, and the calls to 6,120,000. As to private lines, in the first year there were only 186, and that number had since grown to 715, and grown notwithstanding all the difficulties they had had put in their way by a department which he respectfully suggested ought to know better—the Post office, with their restrictions, their obstructions, and general absurdities—and by the difficult questions that had had to be overcome as to way leaves, and so on. There were a good many fallacies about on that subject. The shareholders had heard what had taken place, and how, when they grappled with the questions of danger and disadvantage, all that was said went off into air. What were the facts? He had been surprised to read the other day, in the *Pall Mall Gazette*, an article by

Digitized by Google

Silvanus Thompson, who was an electrical engineer and a philosopher. He did know whether that gentleman had done what Mr. Morgan had done. Mr. Morgan knew what the difficulties were in practice, and they were without any record of the dangers which Mr. Thompson wrote about. The Company, too, had had some experience, and Mr. Thompson felt that. He knew that he could not found upon experience so far, and therefore had gone into "bogey." He said—although nothing had happened in the past four or five years—if you wait long enough you will have such a crop of accidents that will send all your wires underground. The experience the Company had was, moreover, not confined to this country. It required a great deal of tact and determination to overcome the difficulties and prejudices they had encountered. He had been to America, and although he did not run amuck in favour of American institutions generally, America was a go-a-head country, and it put one to the blush that such a country as ours, with such cities as London, Liverpool, and Manchester, should be so far behind. A report had just been put into his hands of the American Bell Telephone Company for last year. They had given the figures relating to the United Company, and he might state that the American company had the astounding number of 123,000 subscribers, the increase in the number for the year ended last January being 25,000. Of course the American company covered more ground than the United Company, but still let them consider for a moment, 123,000 subscribers on one exchange in America in one company! What did that mean? Why, that their American friends had appreciated the enormous advantage of this invention, and were not obstructed as this Company had been by the State. That was the reason for it. Was it worth while listening to them *versus* Silvanus Thompson, or the philosophers, and alarmists, and people who did not trouble to arrive at conclusions based on facts? The report of the American company said:—"It is common to see in the public papers round statements that the wires ought to be at once ordered underground. In this matter we and our associates have the strongest motives for wishing to get the wires underground as far and as soon as it can be done, without destroying the efficiency of the service. The plant would be more permanent and no longer liable to interference from municipal authorities or individuals, or destruction from storms; and its maintenance would be cheaper and easier. There were the motives. But although short trunk lines work fairly well beneath the surface, as shown in Boston and elsewhere, in the present state of the art it is impracticable to put the bulk of the wires underground without interfering seriously with facilities upon which the public are now getting to depend. Conversation over long lines (those reaching the suburbs even) is difficult and often impossible to those who are connected through the underground cables. Were the electrical difficulties overcome, a mixed system would still be needed, as the distribution of the wires would probably have to be overhead, as well as the wires in the more sparsely covered parts of a city. Overhead cables are rapidly coming into use, and as they can be taken on small fixtures, and carry many wires in a small compass, while attracting far less notice than the open wire system, besides being safer in case of storm or fire, their adoption is a step in the right direction, and will go far to remedy the evils of the present overhead system." They themselves had arrived at precisely the same conclusions. Cables were used in place of overhead wires where they could do so; but the real point was this, if they were to have a great public convenience it was sure to be attended with some slight drawback, some possible drawback; and they could not have the telephone, any more than railways, steamboats, and cabs, and obtain the enormous advantages thus secured without some possible drawback. What they had to do was to look before they leaped, and not to be alarmed into doing anything owing to the crotchets of people who aired their views rather easily in the Press. He concluded by endorsing the chairman's eulogies on Mr. Morgan and the staff.

The CHAIRMAN put the motion, which was carried unanimously. In reply to questions he said that they would give ample notice when they required to make a call on the new shares. At present they did not want the money. The shares of the Lancashire and Cheshire Company were saleable to-day at 27s. As to the National Company, they had paid one per cent. dividend, but he did not know what the shares of the Company were worth. If the enterprise in which they were engaged succeeded as they expected, the shares in the National Company, the Northern District Company, and the Telephone Company of Ireland would one day—and not at a very distant date—represent their nominal value.

The retiring directors, Mr. James Brand and Mr. J. S. Forbes, and the auditors, Messrs. Quilter, Ball, and Co., and Messrs. Price, Waterhouse, and Co., were next unanimously re-elected.

The CHAIRMAN, in reply to a question, stated that the agreement with the Globe Company was not yet finished. They had the power to make the agreement, and he did not know that it would be first submitted for the ratification of the shareholders.

Mr. E. H. GALSWORTHY thought it would be unwise to discuss the question, as it was really not before the meeting; and, moreover, he thought the matter might be very well left in the hands of the directors. The meeting then terminated in the usual manner.

TELEGRAPH CONSTRUCTION and MAINTENANCE COMPANY (Limited).

NOTICE is hereby given that the TRANSFER BOOKS of this Company will be CLOSED from the 14th to the 22nd inst., both days inclusive, preparatory to the payment of an ad interim dividend of 12s. per share to all shareholders on the Register on the 14th inst.

By order,
E. DICKENS, Secretary.

38, Old Broad-street, E.C., July 11th, 1884.

CLEVEDON, SOMERSET.

The CLEVEDON LOCAL BOARD of HEALTH are desirous of receiving TENDERS for the PUBLIC LIGHTING of their District for the period of NINE MONTHS, commencing 15th August next, either by Electric Light, Oil, or otherwise. Also for REPAIRING, Painting, Cleaning, Lighting, and Extinguishing the Public Lamps (about 186).

The lamps to be lit at sunset and extinguished at midnight.

Tenders to be sent to me on or before the 29th instant.

The Board do not bind themselves to accept the lowest or any Tender.

HY. C. FRY, Clerk.

Clevedon, 10th July, 1884.

WANTED at once, an intelligent MAN, experienced in manufacture of electric light carbons, to take charge of a small Carbon Plant in a factory near London, S.E. district. State experience and wages required.—Address replies, "Coppered Carbon," care of *Electrician*, 1, Salisbury-court, Fleet-street, London.

THE ADVERTISER seeks a SITUATION as PHYSICAL DEMONSTRATOR. Has had five years' experience at two colleges. Reason for leaving the present position is the rearrangement of classes. Good practical knowledge of electrical testing. Good testimonials. Address, "Ohm's Law," *The Electrician* Office, 1, Salisbury-court, Fleet-street, E.C.

Just Published. Price One Shilling. Second Edition, Enlarged, with 25 Illustrations.

MAGNETO AND DYNAMO ELECTRIC MACHINES.

By J. ANGELO FAHIE, C.E., Member of the Society of Telegraph Engineers and Electricians.

London: E. and F. N. SPON, 16, Charing Cross. New York: 35, Murray Street.

"ELECTRICIANS" WANTED.—Any one who wishes to SELL *THE ELECTRICIAN* of January and February, 1882; April 9, 1882; May 6, 1882; March 25, 1882; August 26, 1882; and February 10, 1883, call at 52, York-terrace, Regent's Park.

FOR SALE, SIEMENS, BURGIN, and GRAMME DYNAMO MACHINES and ARC LAMPS. Little used. Offered at low prices.—Mackay and Mess, C.A., 104, Commercial-street, Dundee.

AUTUMN ELECTRIC LIGHTING.—FOR SALE, ENGINES, DYNAMOS (BRUSH), LAMPS, &c.—Apply Richard Fyfe, 2, Walbrook, E.C.

Digitized by Google

NOTES.

UNITED ASBESTOS COMPANY.—We notice that this company has reduced its capital to £110,000.

ELECTRIC LIGHTING IN NEW YORK.—It is said that the extension of electric lighting in New York has put out no less than 3,000 gas lamps.

LIGHTNING CONDUCTORS.—The current number of the *Edinburgh Review* contains an article on this subject, which we hope to notice at length in a future issue.

EASTERN EXTENSION TELEGRAPH COMPANY.—The coupon of this company's Six per Cent. Debentures, due August 1st, will be paid on and after that date at the Consolidated Bank, Threadneedle-street.

PYRAMID ELECTRIC COMPANY.—Creditors of this company should send in their names and particulars of their claims before the 15th August to the liquidators, Messrs. Foster and Brain, Whitecroft, near Lydney, Gloucestershire.

DIVIDEND.—The directors of Edwin Fox and Co. (Limited), of the Magnetic Telegraph Wire Works, West Ferry-road, E., have declared an interim dividend at the rate of 10 per cent. per annum for the half year ended 30th June last.

SOUTH KENSINGTON MUTUAL ELECTRIC LIGHTING COMPANY.—Creditors of this company should send in their names and particulars of debts to Mr. G. A. Cape, 8, Old Jewry, E.C., the official liquidator, before the 15th August.

THE TREE OF LIBERTY AT STRASBURG.—A heavy thunderstorm broke over Strasburg on Thursday, the 17th inst., during which the lightning felled to the ground the tall poplar planted in 1792 to commemorate the advent of the Republic.

ANGLO-AMERICAN TELEGRAPH COMPANY.—This company, after placing £37,500 to the renewal fund, have declared an interim dividend for the past quarter of 17s. 6d. per cent. on the Ordinary, and 35s. per cent. on the Preferred stock.

KELWAY'S ELECTRIC LOG SYNDICATE.—The 12th of August has been fixed as the last day for receiving the names of creditors of this company, and particulars of their claims. Mr. E. J. Morris, of 58, Lombard-street, E.C., is the liquidator.

VOLTAMETERS.—After experimenting with various liquids, M. Guillaume finds that the distance between the electrodes, which has but little influence in a sulphate of copper voltameter, has considerable effect in a sensibly pure water voltameter.

PATENT EXAMINERS.—An examination for the post of assistant examiners in the Patent Office will be held shortly. Applications will be received up to 29th August, and all particulars can be had of the secretary, Civil Service Commission, London, S,W.

THE TELEGRAPH IN SIAM.—*The Times* correspondent at Bangkok says:—"The construction of a telegraph line has been sanctioned, and will be pushed on and completed in the next dry season, from Bangkok to Zimmay, and thence afterwards to Burmah."

ELECTRIC LIGHT MATERIAL WANTED.—Tenders are invited for the supply of dynamos and lamps for various installations of incandescent lamps. Tenders are to be forwarded, before 2nd of August, to Mr. W. C. Martin, electrical engineer, Commercial-street, Dundee.

ACCIDENT FROM LIGHTNING.—On Wednesday, the 16th inst., during a storm, a house in the village of Chantemerle, Geneva, was struck by lightning and set on fire. There being no water available to extinguish the flames the fire spread, and the whole village was reduced to ashes.

ELECTRIC LIGHTING IN WORKS.—The new British Iron Company have recently increased the number of arc lamps in their works at Corngreves, near Cradley. It will be remembered that several Weston lamps were put up in these works some time since by the Maxim-Weston Company.

ELECTRIC LIGHTING IN VIENNA.—It is stated that the Office of Works for the City of Vienna has approved of a specification for the lighting of portions of the new Rathhaus with electric lamps. It is to receive the sanction of the magistrates and common council, and then tenders will be invited.

SUBMARINE TELEGRAPH COMPANY.—The accounts of this company for the half year ending June 30, show a balance, subject to audit, which enables the directors, after adding 15 per cent. of the gross receipts to the reserve fund, to recommend a dividend at the rate of 13 per cent. per annum.

THE NEW ATLANTIC CABLE.—*The Times* correspondent at Philadelphia telegraphs, under date July 21, as follows:—"In a telegram from Dover Bay, New Hampshire, it is stated that the laying of the new cable has been completed, and that messages are successfully passing between Dover Bay and Waterville in Ireland."

ELECTRIC LIGHTING ON RIVER STEAMERS.—The Hudson River steamer St. John has, says an American contemporary, been furnished with Edison electric lamps on quarterdeck, in kitchen, and in dining room, as an experiment. The success has been sufficient to lead to the extension of the system to all parts of the steamer, and it will also be placed on the Drew, of the same line.

ELECTRIC LIGHT WORK IN 1883.—We have received a copy of a pamphlet by M. Ph. Delahaye, a well-known French engineer, entitled "L' Industrie de l' Eclairage Electrique en 1883." It is a reprint of a paper read by M. Delahaye at the recent Congress of the Société Technique de l' Industrie du Gaz held in Paris, and contains some interesting figures as to the relative cost of gas and electric lighting.

FAURE ELECTRIC ACCUMULATOR COMPANY.—The creditors of this company should send in their names and claims before the 14th August to the liquidators at the office of Messrs. Cooper Brothers and Co., of 14, George-street, Mansion House, E.C. Vice-Chancellor Sir J. Bacon has made an order for the winding up to be conducted under the supervision of the Court of Chancery.

THE MONARCH CABLE STEAMER.—On Wednesday week this cable ship completed the repair of the Forth cable, which had been damaged close to the Burntisland shore. On Wednesday last she laid a cable between Barra and the mainland of Orkney, thus connecting the principal southern islands and fishing stations of Orkney with Kirkwall. After replacing one of the Shetland cables, broken last winter, she was to proceed to the Isle of Man.

THE TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.—At the meeting of this company held this week, a report of which appears in another column, the chairman, Sir Daniel Gooch, stated that they had manufactured 4,322 miles of cable in the last six months, and laid over 4,800 miles. They were hard at work, he said, endeavouring to complete the lighting of Paddington station, and hoped to have all ready by November or December.

ELECTRIC LIGHTING AT WALHAM GREEN.—At the fête of the Butchers' Charitable Institute at Walham Green on the 15th inst. the grounds, ball marquee, and tents were beautifully illuminated with six arc lights and fifteen Woodhouse-Rawson incandescent lamps of 20 candle-power. The steadiness of the arc lights was commented upon by all present. The work was carried out by Messrs. Woodhouse and Rawson, and the installation consisted of an eight horse-power portable engine, with separate dynamo machine for arc and incandescent circuits.

EARTHQUAKES.—On the night of the 19th inst. an earthquake was felt at Agram. It lasted four seconds, and was accompanied by subterranean rumblings. No damage was done.—A telegram from Rome, dated July 23, says: A strong shock of earthquake, accompanied by loud subterranean rumblings, was felt at twenty minutes to one o'clock this morning at Forio, in the island of Ischia. No damage was done, but in a telegram to the *Stampa* it is stated that it is impossible to describe the consternation of the inhabitants, who anticipate a renewal of last year's catastrophe.

CRICKET MATCH.—The annual cricket match between teams of the Manchester and North Lancashire District of the Lancashire and Cheshire Telephonic Exchange Company was played at Ewood Park, Blackburn, on Saturday, July 12, and after a very pleasant and enjoyable game ended in a victory for North Lancashire District by the narrow majority of six runs. Afterwards the members of the Manchester team were entertained at the White Bull Hotel, when a very pleasant evening was spent, during which several members of the two districts gave a sample of their musical vocal powers.

HAIL.—M. Colladon, of Geneva, has observed some remarkable movements on the part of particles of sleet, which, remaining motionless for one or two seconds after their fall, were afterwards projected to a height of ·25m. or ·30m., as if by an impulse imparted by the earth. This curious phenomenon was noticed in two falls of sleet at Geneva, one on the 19th January, 1881, the other in March, 1883, and a third time during a fall of hail at Hauts-Crêts, at the summit of the hill of Cologney. Mr. Colladon quotes two other similar observations of M. Melsens, published in *La Lumière Electrique* for 26th February, 1881.

REIS'S TELEPHONE.—At the last meeting of the New York Electrical Society Professor VanderWeyde, the president, exhibited copies of the Reis telephonic apparatus, made from the original designs of 1860. The exhibition included working models of the various receivers and transmitters of Reis, with improvements of his own. The professor stated that he gave an exhibition of these instruments as long ago as January 7, 1869, in that very room, at which time the persons present thought they could distinguish articulate sounds, although he then thought it impossible. All that he imagined it to be capable of doing was the transmission of musical sound.

ELECTRIC LIGHTING IN DETROIT.—The city authorities of Detroit, Michigan, having executed a contract with the Brush Electric Light Company to light the city by means of the tower system, two citizens, stockholders in the Excelsior Electric Light Company, have filed a bill in Chancery, and applied for an injunction to restrain the city from carrying out the contract, on the ground that proposals were not received and the contract not awarded in accordance with the terms of the charter. The parties to the suit also ask that the Brush Company be enjoined from erecting towers in the public streets and places. No preliminary injunction was asked for, and the case will be tried on its merits.

RAIN TO ORDER.—A French electrician, says a contemporary, suggests the following method for producing rain as required. His plan is to send up one or more balloons freighted with panclastite or some other equally explosive compound. They are to be connected with a battery on the ground by means of a fine wire, and when they attain the necessary altitude—that is, when they enter the cloud-zone—the spark is to be transmitted. The detonation will follow, and a refreshing shower will be the result. We noticed in these columns not so very long since that a Victorian colonist had laid plans before the Government of that colony for producing the same happy result in identically the same way. If the idea ever becomes a practical reality we may find political parties making use of it to disperse open-air meetings of their opponents. What an effect might not a heavy downpour have had upon the Franchise meeting in Hyde Park on Monday, for instance?

SHIP LIGHTING.—The latest addition to the fleet of the Glasgow and Steam Shipping Company is the "Thistle," which has been built by Messrs. Henderson and Co., Partick, Glasgow, and lighted, to the specifications of Professor Jamieson, by the Pilsen Electric Light Company, of London, with 41 Gatehouse lamps, each of 20 candle-power actual. The ship is wired in four distinct circuits, all being controlled from one switchboard in the engine room. The lamps in the saloon are fitted with switch holders, so that any lamp may be turned out at pleasure. The machine is compound wound, of the Pilsen-Schuckert type, manufactured by the company, having an armature of the hoop-iron construction, and only requiring a speed of 450 revolutions to give the necessary current, which is 25·4 amperes, or ·62 per lamp. The engine is a Westinghouse high speed, built by Messrs. Alley and M'Lellan, of Glasgow, and fitted by them to the same bed plate as the dynamo. We understand the work has been carried out to the entire satisfaction of the owners and the consulting electrician, and reflects great credit on the company.

ELECTRIC LIGHTING IN HULL.—At a meeting of the Lighting Committee of the Hull Town Council, held on Thursday week, the town clerk reported that on the 10th inst. the council passed a resolution rescinding the contract with Messrs. Siemens for lighting the Old Town with electricity from the 28th inst. He had given the necessary notice to Messrs. Siemens, and requested them to make arrangements for removing all their plant and machinery, and had received a letter in reply informing him that the necessary instructions would be given for the removal of the plant. Some discussion arose amongst the members of the committee as to whether tenders should not be invited from other firms for electric lighting, and many were by no means pleased to learn that the Works Committee had that morning passed a resolution to light the Old Town with Sugg's lamps. In the end it was resolved, on the motion of Mr. Hall, seconded by Mr. Grindell, that the committee be instructed to give the borough engineer instructions to obtain tenders for, and report to the committee on, the best means of lighting the public lamps and the Town Hall within the area at present lighted with or without electricity.

THE ELECTRO-CHEMICAL EQUIVALENT OF SILVER.—In the *Journal de Physique* for July M. Mascart has an article in which he gives an account of recent experiments undertaken by him to determine the weight of silver deposited or dissolved during one second by a unit of current. Some few months ago he arrived at the conclusion that the quantity was 11·24 m.g. Kohlrausch gives 11·36, and Lord Rayleigh 11·19. Since these determinations F. and W. Kohlrausch by a fresh series of experiments have found it to be 11·183, and Lord

Digitized by Google

Rayleigh has recently, March, 1884, made it 11·18. Accordingly, M. Mascart thought it necessary to re-verify his calculations, and acknowledges that he was deceived. Without going into his calculations, we may say that he now gives his result as 11·156 mg. The chemical action of one ampere per second, or of one coulomb, will therefore be, says M. Mascart:—

According to Kohlrausch...		1·1183 mg. of silver dissolved.		
Ditto	Rayleigh ...	1·118	ditto	ditto
Ditto	Mascart	1·1156	ditto	ditto

Lord Rayleigh's method of determination and the results obtained will be found described at p. 607 of our last volume, *Electrician*, May 10, 1884.

The Turks and the Telegraph.—The Turkish Government exercises a very wide discretion as to what may and may not be despatched or received per telegraph wire in its dominions. Thus *The Times* correspondent at Constantinople states that "For some months past any telegram containing direct or indirect reference to Egyptian affairs has been considered objectionable, and even the Queen's Speech at the opening of Parliament was suppressed for that reason. At present this oppressive kind of censure can be patiently borne, because newspapers and letters are received through the foreign post-offices, and telegrams can be easily sent through the same channels to some telegraph office beyond the frontier. But if the postal communication falls into the hands of the Turkish authorities, this means of softening the rigours of the present absurd system will be destroyed, and foreigners in Turkey may be condemned to isolation almost as complete as if they lived in Central Africa." The Turks are evidently of one mind with the Boer, whose opinion was that telegraphs were a nuisance. If the news were worth having, he opined that it would keep, and if bad he thought it had better not come at all.

The Electric Light for War Purposes.—On Thursday night a series of trials were to be carried out at Aldershot to test the applicability of the electric light to the purposes of searching for the wounded. Lord Hartington was to be present, together with a number of the Army Medical Department and representatives of the War Office. A parade of the garrison was ordered for 9 p.m., when the experiments were to begin. The apparatus employed was to consist of Messrs. Sautter, Lemonnier and Co.'s portable electric light tackle, with engine, dynamo, and lamp on one carriage, very similar to that illustrated in *The Electrician* for July 1, 1882, Vol. IX., p. 153. This portable apparatus is used in the French army to a considerable extent. It will be remembered that at the time of the Vienna Exhibition the Austrian Government carried out a series of experiments of identical character with those made on Thursday night at Aldershot, the results being only partially satisfactory. Sautter and Lemonnier's apparatus was used on this occasion also. A short notice of these experiments will be found in our issue for Oct. 27, 1883, p. 555. We shall give further details of the Aldershot trials in our next issue.

The Telephone in Plymouth.—The *Western Morning News*, of the 17th inst., has some very hard things to say of Mr. Fawcett concerning the telephone business in Plymouth. Our readers are well acquainted with our view of the question. Here is the view taken by our western contemporary:—"Much was hoped from placing so able and enlightened a statesman as Mr. Fawcett at the head of the Post Office, and proportionately great is the disappointment at finding that in the matter of the telephone and telephone exchanges there is nothing but procrastination, repression, and narrowness, resulting in financial failure and public inconvenience. In Plymouth, Devonport, and Stonehouse, three years ago, there were 150 residents, each of whom could speak to the other through a telephone exchange. But official pique on the part of the Post Office put a stop to this, and established a so-called Post Office Exchange. The number of members has never exceeded forty-six; it has now fallen back to forty-two; and several other subscribers have given notice to leave unless the numbers are so increased as to make the exchange really worthy of the name. Plymouth is but a sample of nearly every other town where the Post Office monopoly has taken effect and Post Office Exchanges have been instituted. But for the Postmaster-General's veto a real and useful exchange might be established in the three towns next week, at a subscription far less than that which the Post Office demands."

Recording the Vibrations of a Tuning Fork.—The exact determination of the rate of vibration of a tuning fork by means of the siren has heretofore been attended with errors resulting from imperfections of the recording gear and difficulty of maintaining and counting the beats of the two tones. These errors have been sought to be removed by obtaining autographic records of the rate of the siren and of the difference between this rate and that of the fork. The experimenter, while obtaining these results, being freed from the necessity of even counting the beats, no personal element enters into the observation, and the records, being permanent, can be studied at leisure. The apparatus with which these results are obtained is described in the *American Journal of Science*, the method employed being the following:—A strip of chemically prepared paper, which rests on a metal wheel, being drawn by clockwork under three platinum pens placed in electric circuits, three simultaneous electro-chemical records are obtained. One of these is a line of dots made at the rate of one a second, by a chronometer placed in the circuit of the same battery with one of the pens. The second is a row of dots made by a closing of the same circuit by a siren once in each revolution, while singing nearly in unison with the fork. The third is a row of dots made by the closing of the circuit of a second battery, once for each beat of the fork and siren. It thus results that from the same strip of paper can be counted the number of revolutions made by the siren in any number of seconds (which gives the number of impulses produced by the siren) and the number of beats in the same time, which is the difference between the number of shocks imparted to the air by the siren and the number imparted by the fork. The record being made without throwing any work upon the fork, the rate of vibration of the unconstrained fork results.

A Peroxide of Lead Cell.—In his excellent report to the United States Government on "Submarine Mines," Colonel Abbot makes the following remarks on the peroxide of lead cell: "In 1876, Charles T. Chester introduced in New York, under the name of 'magazine battery,' the De la Rive peroxide of lead cell. This element is remarkable for its high electromotive force, and, among single fluid cells, for its constancy of action. The depolarising substance is expensive; and, as put upon the market, it contained traces of nitric acid, which proved destructive to the zincs. Notwithstanding the latter defect, the cell exhibited incontestable merits. Two cells were tested. In both the negative plate consisted of a carbon plate embedded in peroxide of lead contained in a porous cup. This cup was 3 inches in diameter and 5·5 inches high. The positive plate was the common Leclanché cylinder of zinc, ½in. in diameter and 7in. long. They were placed in a cylindrical glass cell, 4in. in diameter and 6in. high, half filled with fluid,

which for one cell was dilute sulphuric acid (1 part of acid to 14 parts of water), and for the other cell a saturated solution of sal-ammoniac. The internal resistance of the former at the first closing of the circuit was 1·7 ohm, and at the end of the trial 7·5 ohms. These cells were allowed to stand for a few days without closing the circuit, and the change in electromotive force was noted by Law's method as follows: Feb. 19, 1876, acid cell, 2·305 volts; sal-ammoniac cell, 1·800 volts. Feb. 24, acid cell, 2·128 volts; sal-ammoniac cell, 1·664 volts. Feb. 25, acid cell, 2·057 volts; sal ammoniac cell, 1·689 volts. Feb. 26, acid cell, 1·994 volts; sal-ammoniac cell, 1·642 volts. They were then placed at work continuously for five days. After a rest of two days, and a re-amalgamation of the zincs which had begun to suffer, the circuit was again closed, the electromotive force being 1·580 and 1·490 volts respectively. At the end of the thirty-third day both cells were exhausted, new zincs and fluids being required. About a minute after the circuit was finally broken, the electromotive force of the acid cell was ·471 volt, and of the other, ·803 volt.
